

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

### Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

### About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

# CHEMICAL ABSTRACTS

Vol. 13.

JANUARY 10, 1919.

No. 1

## 1. APPARATUS.

L. C. JONES.

A device for introducing a vapor into a gas. E. H. ZEITFUCHS. *J. Am. Chem. Soc.* 40, 1899(1918); illus. E. J. C.

A simple method of rapidly and accurately calibrating pipets. S. ENGLISH. *J. Soc. Glass Tech.* 2, 216-9(1918).—Original graduations are seldom correct. The error due to (1) inaccuracy of first calibration or (2) change due to afterworking of the glass may be as great as 0.2 cc. Afterworking may be minimized by annealing and allowing the pipet to stand for a month or so before calibration. Calibration by weighing, if carefully done, takes at least 15 min. An improved rapid method consists in (1) inverting the pipet over one stopper of a 2-necked Woulfe bottle, the other neck of which is connected to a H<sub>2</sub>O reservoir at higher level, (2) filling the pipet, (3) running the H<sub>2</sub>O back into the bottle, which at the same time forces an equal amt. of displaced H<sub>2</sub>O to flow into an auxiliary bulb with calibrated neck, this bulb having been previously calibrated against a standard pipet. Details are given. The method is rapid, 30 pipets per hr. being handled. C. H. KERR.

Apparatus for measuring chimney heat loss (CHOPIN) 21. Theory of the thermionic amplifier (VAN DER BIJL) 3.

Sulfur burners. PRATT ENGINEERING & MACHINE CO. Brit. 118,097, July 13, 1918. A method of burning S consists in maintaining in a chamber a pool of molten S, and in considerably increasing the surface area exposed to the combustion air, e. g., by spraying the S in fountain-like jets by means of air blasts delivered into the pool. The air supply in the vicinity of the pool is restricted to the amt. for volatilizing the S at the desired rate, and the oxidation is completed in a series of combustion chambers. A suitable app. is specified.

## 2. GENERAL AND PHYSICAL CHEMISTRY.

WILLIAM D. HARKINS AND E. B. MILLARD.

The trained man of science in the war. J. S. AMES. *Science* 48, 401-10(1918). E. H.

The ionic theory of solid substances. A. L. BERNOULLI. Univ. Basel. *Helvetica Chimica Acta* 1, 289-96(1918); cf. *C. A.* 12, 2468.—Nernst and Lindemann have computed the mol. heat capacity of rock salt and sylvine from the data of Rubens and Hollnagel on the wave length of the residual rays. This is in good agreement with the thermal data. Koref gives a method of calcg. the frequency of each atom in a binary compd. from the m. p., and mol. vol. of the compd. and the at. wt., at. vol. and density of the elements. This is supported by the exptl. work of Russel, which showed the change in the frequency on entering into chem. combination. Hence the absorption bands in a chem. compd. are not exactly identical with those of the components. In

the previous article the formula of Einstein for the calcn. of the wave length from vol. elasticity in the case of monatomic metals was subject to a correction. This theory is now extended to polyatomic compds. From X-ray analysis it is known that rock salt is composed of a cubic lattice with Cl and Na atoms at alternate corners. Thus the salt consists of ions and is completely dissociated. On this assumption the wave length is found as before. For binary compds.  $\lambda = 657.6 \rho^{1/6} \cdot \sqrt{x} \cdot M^{1/2}$ , where  $\rho$  is the d.,  $x$  the coeff. of cubical compressibility, and  $M$  the mol. wt. of the ion constituent. The derivation is admittedly not rigid. Observed and computed values for  $\lambda$  are given, in the case of NaCl, KCl, KBr, KI, CaCO<sub>3</sub>, CaF<sub>2</sub>, and SiO<sub>2</sub>. For NaCl the agreement is considered good. In KCl, the frequencies of the K<sup>+</sup> and Cl<sup>-</sup> are so close together as to be hardly distinguishable by this method. For CaCO<sub>3</sub> and SiO<sub>2</sub> the simplifying assumptions do not hold, but the agreement is fair. For Na<sup>+</sup> in NaCl  $\lambda$  observed = 53.6 and  $\lambda$  calcd. 54.9; for Cl<sup>-</sup> observed  $\lambda$  = 53.6 and calcd. 50.3. Examples are given of the computation of elasticity data from wave length. From the kinetic theory the wave lengths of the 2 constituents of a compd. should be related to the at. wts. of the ions by the equation  $\lambda_2 = \lambda_1 \sqrt{M_2/M_1}$ . B. shows this to be the case for NaCl, KBr, and CaF<sub>2</sub>. F. C. HOYT.

The heat of dissociation of diatomic gases in connection with the increased values of  $\sqrt{a}$  for free atoms. J. J. VAN LAAR. *Chem. Weekblad* 15, 1124-37(1918).—No noteworthy exceptions have been observed to the rule that the values for  $b$  and  $\sqrt{a}$ , in the van der Waals equation of state, are additive. The quantity  $b$  is quite independent of whether the atom is free or combined; but  $\sqrt{a}$  depends largely on this factor. The central atom in such compds. as CH<sub>4</sub>, NH<sub>3</sub>, SiCl<sub>4</sub>, etc., exerts no attraction outside the mol.; hence in these cases  $\sqrt{a} = 0$ . A double bond gives partial freedom, so that in C<sub>2</sub>H<sub>4</sub>  $\sqrt{a}$  becomes 1.55; and a triple bond gives full freedom, so that in C<sub>2</sub>H<sub>2</sub>  $\sqrt{a}$  has the full value of the C atom, 3.1. This rule of the additivity of  $\sqrt{a}$  explains observed facts much better than the valence rule of Mathews, to which many serious exceptions occur. For atoms in the free state, the values are greatly increased (30 to 40 instead of 1 to 11). This increase represents the actual valence attraction, while the lower values in compds. represent residual attraction. Certain elements at their crit. temps. show partially increased values of  $\sqrt{a}$ , indicating dissociation. The following examples are cited: As<sub>4</sub>, 20% dissociated; Se, 30%; Te, 80%; Br<sub>2</sub>, 5%; I<sub>2</sub>, 10%; P<sub>4</sub>, not dissociated. Atomic C gives a value of 32, which is 10 times the value for the C atom in compds. Te has the peculiarity of exerting its entire residual attraction even in the compd. TeCl<sub>4</sub>, the value of  $\sqrt{a}$  being 9 instead of 0. This is ascribed to the high at. vol. of Te. A similar effect is noted in SbCl<sub>3</sub>, and to a less extent in PCl<sub>3</sub>, POCl<sub>3</sub>, AsH<sub>3</sub>, AsCl<sub>3</sub>, and SbH<sub>3</sub>. That the central atoms in such compds. as CCl<sub>4</sub> and SnCl<sub>4</sub> exert no outside attraction has the effect of making the crit. temp. much lower than it would otherwise be. Thus, calcg. the crit. temp. of CCl<sub>4</sub> on the assumption that  $\sqrt{a}$  is increased by 3.1 (the normal residual attraction of the C atom) gives 453° instead of the actual value 283°. On the other hand, elements occurring in the atomic state, in which  $\sqrt{a}$  is increased by the valence attraction, have extremely high crit. temps. The metals are the most important examples. If free C were associated to C<sub>2</sub> its crit. temp. would be about -150°. The author shows, from mathematical considerations based on the van der Waals equation of state, that the heat of dissociation of H<sub>2</sub>, N<sub>2</sub>, O<sub>2</sub>, etc., is completely accounted for by the increase in energy due to the valence attraction of the liberated atoms. Upon the same basis he presents calcns., from the known heats of dissociation of H<sub>2</sub>, N<sub>2</sub>, O<sub>2</sub>, Cl<sub>2</sub>, Br<sub>2</sub> and I<sub>2</sub>, of the values of  $\sqrt{a}$ . These support the contention stated above. The paper closes with a criticism, in the nature of a general polemic, against those who foster the fallacy of connecting the Nernst heat theorem with the equation of Gibbs (1878), Planck (1887) and others for the dissociation of gases.

JULIAN F. SMITH.

**Relation between vapor pressure and temperature.** M. KATAYAMA. *J. Tokyo Chem. Soc.* 39, 547-84(1918).—In the well-known vapor-pressure formulas, the pressure is represented as a function of temp. K., expressing the sp. heat of liquid and gaseous phases as a function of temp., has transformed the formulas of Clausius and Clapeyron into:  $A - (B/T) = \log p + C_p^n - D_p^{2n}$ , in which  $n = 1/2$  and  $C = 0.05875 + 20.05D$ . Therefore  $A - (B/T) = \log p + 0.05875 p^{1/2} + D(20.05 p^{1/2} - p^{1/2})$ , which gives a result in satisfactory agreement with observations by other investigators. The constants  $C$  and  $D$  have some relation to the association of liquid. S. KOMATSU.

**Determination of the normal density of ethylene.** T. BATURCAS. *Helvetica Chimica Acta* 1, 136-41(1918); *J. chim. phys.* 16, 322-49(1918).—Data for the exact d. of ethylene are old and unreliable or inadequate. The investigations of Bretschger and Stahrfass are inadequate in that the gas was obtained from but one source. B. prepared the gas by the four following methods: (1) dehydration by phosphoric acid, (2) dehydration by boric anhydride, (3) dehydration by  $H_2SO_4$ , (4) catalytic dehydration by Al. The gas was purified by washing with KOH, refractionating, and by scrubbing with the liquefied gas. The results showed that the purification was very satisfactory. The density was detd. by the balloon method used in Geneva. Although Hg is not attacked by ethylene a paraffin oil manometer was selected, since it is 15.5 times as sensitive as a Hg manometer. Thus the slightest variations in pressure were easily noted. The balloons used had a vol. of 0.6 to 0.8 liter. The mean density values obtained represent the result of about seven detns. per balloon. (1) 1.26021, (2) 1.26024, (3) 1.26042. The density of ethylene is then 1.2603 under normal conditions. T. SHEDLOVSKY.

**A consideration of causes for abnormal boiling points.** A. BERTHOUD. *J. chim. phys.* 16, 245-78(1918).—Polemical. Contrary to Forcrand's (cf. *C. A.* 12, 886) opinion, mol. dissociation tends to raise the b. p. of a pure liquid appreciably. The hypotheses of Forcrand, according to which the abnormal b. ps. of water, HF and  $NH_3$  would be related to the heats of formation and to the dissymmetry of the mols., do not conform to the facts. The calcs. based on the addition of the const.  $\sqrt{a}$  and  $b$  of van der Waals presented by van Laar show that, of the substances studied, AcOH is the only one whose relatively high b. p. and critical temp. may be explained by association alone. In the case of water, alcs., and ammonia another factor enters. These substances have abnormal critical pressures, not accounted for by mol. association. The cause which produces these great critical pressures and also helps raise the b. p. and critical temp. of water and alcs. is found in the particularly high value reached by the const.  $a$ , independently of mol. association, in those substances which contain the OH group. In the case of  $NH_3$  there is a greater diminution in the const.  $b$  than in the const.  $a$ . T. SHEDLOVSKY.

**Cineole as a solvent in cryoscopy.** C. E. FAWSITT AND C. H. FISCHER. *J. Roy. Soc. N. S. Wales* 51, 467-72(1917).—The f. p. of cineole has been found to be  $0.9^\circ$  instead of  $-1^\circ$  as usually given. With benzophenone, nitrobenzene, bromobenzene, toluene, benzene, and chloroform as solutes the cryoscopic const. has been found to be 6.7.  $Et_2O$ , EtOH and butyl alc. give lower values. The latent heat of fusion for cineole is calcd. to be 22.2. D. MACRAE.

**Silicic acid gels.** HARRY N. HOLMES. Oberlin College. *J. Phys. Chem.* 22, 510-19(1918).—H. gives a method for making  $SiO_2$  gels which will set in a given time. He also studies the effect of high H-ion concn. and of temp. on the time of set.  $CO_2$ -free water-glass is poured into an equal vol. of acid and stirred quickly. The electrolyte is not removed. The mixt. is considered set when a tube of it can be inverted

and tapped without causing the gel to flow out. The set occurs most rapidly for slightly basic mixts. A plot is given showing the time of set for several different concns. of a few acids. As the H-ion concn. increases, the time of set is delayed, but at great concns. the time of set again becomes measurable; 24 *N* H<sub>2</sub>SO<sub>4</sub> gives an immediate set. Fleming stated that the time of set depends only on the catalytic effect of H- or OH-ion concn. of silicic acid, and the temp. Since Fleming did not work at high concns., he did not notice that here the time of set decreases again. While at low concn. the H-ion exerts the greater influence on the time of set, above a certain concn. the dehydrating effect predominates. Increased temp. hastens the time of set, the accelerating effect being between the temps of 20° and 60°. At higher temps. the dehydrating effect of non-ionized mols. probably decreases; therefore, the time of set will be about the same with any acid, if these are of the same strength. The dehydrating influence of non-ionized mols. must be considered as a factor in detg. the time of set of gels.

A. W. CONTIERI.

**Investigations on the imbibition of water by gelatin.** E. B. SHREVE. *Science* 48, 324-7 (1918).—The imbibition of water by gelatin gels depends not only on the concn. of the gel used, but also on its previous history with respect to the concn. to which the original gelatin soln. was made up. Of two gels of the same concn. of which one was made by evapn. of a dil. soln. of gelatin and the other from a more concd. soln., the first shows greater imbibitory power than the second. Freshly cut cubes of gel immersed in water show equal ratios of increase along all 3 dimensions, but if they have previously undergone evapn. the increase is greatest on those dimensions perpendicular to the surfaces from which most evapn. has occurred, *i. e.*, the distribution of amt. of increase along the 3 dimensions is in the same ratio as the diminution by shrinking has been. The evapn. of water from the surface of gelatin changes in some way the physical structure of the gelatin; therefore, for reproducible results it is necessary to see that the original compn. of the gelatin soln. is always the same, that the previous history of all the gel used is the same and if water loss is to take place before absorption then pieces of identical shape must be used, and all measurements must be made on similar axes.

H. I. MATTELL.

**The osmotic action of cane sugar, silver nitrate, and lithium chloride in pyridine when separated from pyridine by a rubber membrane.** ALFRED E. KOENIG. *J. Phys. Chem.* 22, 461-79 (1918); cf. *C. A.* 2, 3181.—The first part of the paper gives a detailed description of the app. used, together with an account of the methods employed to obtain pure reagents. The osmotic pressure of sugar in pyridine is in good agreement with the value demanded by the gas laws, the 0.1 *M* soln. showing the closest agreement. The osmotic pressure of AgNO<sub>3</sub> is much lower than the theoretical value. LiCl also shows values which are too low even on the assumption that the salt is undissociated. By using different membranes, different values for the osmotic pressure are obtained. This fact K. considers as being in accord with the selective or chem. theory of osmosis, maintained by Kahlenberg. The pressures, after reaching a max., decreased. This seems to be due to an alteration in the nature of the rubber membrane due to its contact with pyridine, as a used membrane shows lower values than a fresh one. The pressure obtained, therefore, depends on the nature of the membrane employed.

A. W. CONTIERI.

**The thermo-electricity of tungsten.** H. PÉCHEUX. *Compt. rend.* 167, 487-9 (1918).—Here are recorded the results of a study of the resistivity and thermo-elec. power of three W filaments containing various amts. of Fe. The increase of resistivity with temp. is considerably less with those richer in Fe. W lies between Cu and Pt in the thermo-elec. series, and Cu is between Ta and W.

G. L. CLARK.

The coefficients of magnetization of oxygen and nitric oxide, and the theory of the magneton. E. BAUER, P. WEISS AND A. PICCARD. *Compt. rend.* 167, 484(1918).—Three methods for measuring coeffs. of magnetization are described. In two of these the magnetic value of water is measured first in an atm. of  $H_2$ , and then in the gas studied, the susceptibility being thereby obtained by the formula  $x = x_0 \cdot (h - h_0)/h_0$ , where  $x_0$  is the susceptibility of water. Certain systematic errors are found and corrected. For example, the soln. of a magnetic gas in water lowers the diamagnetic susceptibility 4 to 6 per 1000. But if water changes its properties from one expt. to the next and if it dissolves only some  $H_2$  without influence upon its susceptibility in detg. the value of  $h_0$ , while it absorbs some paramagnetic gas in detg.  $h$ , the error may be as great as 3.3 per 100 for  $O_2$  and 5 per 100 for NO. The third method is new and independent of these variations: A horizontal column of paramagnetic gas is in access to the atm. at one end and the other is in a magnetic field. By means of a small  $H_2O$  manometer the excess pressure in the field over the exterior pressure is directly measured. The following values are obtained ( $x$  = coeff. of magnetization and  $\sigma$  = magnetic moment per g.-atom or mol.):

$$(O_2) \quad x_{20} = 1.077 \times 10^{-4} \pm 0.003 \times 10^{-4}; \sigma = 1.587 \times 10^4.$$

$$(NO) \quad x_{20} = 0.487 \times 10^{-4} \pm 0.0025 \times 10^{-4}; \sigma = 1.033 \times 10^4.$$

Dividing by the g.-magneton deduced by Langevin from kinetic considerations, 1123.5, there is obtained for the atom of O  $n = 7.06$  and for NO  $n = 9.20$ , two values which are not whole numbers and whose deviations therefrom cannot be attributable to exptl. error. These facts contradict the theory of the magneton; either O and its compds. are exceptions to the general law or the observed discordances indicate disagreement between the classic kinetic theory and the facts. G. L. CLARK.

The equilibrium between carbon monoxide, carbon dioxide, sulfur dioxide and free sulfur (FERGUSON) 6.

### 3. SUBATOMIC PHENOMENA AND RADIOCHEMISTRY.

---

GERALD L. WENDT.

The radioactive properties of the mineral springs of Colorado. O. C. LESTER. Univ. Colo. *Am. J. Sci.* 46, 621-37(1918).—This investigation covers some 200 springs in Colo. They show a high average activity. Though some are inactive, some (as high as  $305 \times 10^{-10}$  curie Ra Em per l.) are the most active yet found in the U. S. and are surpassed by but few foreign springs. The greatest activity of spring gases (1280, in the same units) is exceeded in the world only by a few springs in the Yellowstone National Park. Location of the springs is not given. No connection was found between the activity of the water and its chem. properties or its temp., nor between the activity of water or gas and that of solid deposits. Of the active springs 61% are in pre-Cambrian formations, 14.7% in igneous rock and 24.2% in sedimentaries of various formations. There is no connection between active springs and the location of deposits of Ra ores. The most active springs are found on both slopes of the Continental Divide and not far from it, and no bodies of radioactive ores are near them. The activity of the waters is probably slowly accumulated by long flow over weakly active material. If there had been contact with Ra ore deposits the activity of the water would have been of quite different magnitude. The "boiling-out" method was used for the detn. of the Ra Em in the waters. G. L. WENDT.

Polarization measurements at wire cathodes in separately ionized gases. C. A. SKINNER. *Phys. Rev.* 12, 136-42(1918); cf. C. A. 11, 909. 1783.—A report on the

wire cathode in separately ionized O and H. If  $V_b$  is the polarization p. d. and  $j$  the current density at the cathode for both plates and wires the ratio  $V_b/j^2$  is constant over a considerable range of polarization potentials. The lower limit of this range is detd. by the temp. of the positive ions and their reflection constant, and has practically the same value for both H and O, viz., 10–11 v. The upper limit for H is about 80 v. and for O about 140 v. If it is true that under this bombardment potential the liberation of electrons from the cathode becomes sufficient appreciably to increase the ionization in the surrounding gas, it must be concluded that H ions produce at 80 v. velocity what O ions require about 140 v. to accomplish. The upper limit is about the same for both plates and wires, while the lower limit for wires is slightly lower than that for plates.

A. L. FEILD.

**Simplified theory of the cathode fall in gases with application to plates and wires.** C. A. SKINNER. *Phys. Rev.* 12, 143–57(1918).—It is shown that an extremely small electron current, conceived to be liberated from the cathode under the bombardment of the positive ions, may account for the ionization between the cathode and the negative glow. Since  $1/2$  the current in the negative glow is carried by positive ions, and the rate of production of ions at any pt. is proportional to the total rate of ionization between that pt. and the cathode, it follows that: at one ionizing interval from the negative glow toward the cathode, the positive ions carry  $3/4$  of the current; at two ionizing intervals  $7/8$ , and so on. It is conjectured that the actual conditions may be effectually represented by assuming a localized source of ions either in the negative glow or somewhat nearer the cathode. With this as a basis the resulting potentials between the effectual source and the polarization region at the cathode are calcd. for both plane and cylindrical cathodes. The theory is exptly. tested with Al cathodes in H. With a plate cathode the effectual source lies somewhat nearer the cathode than the point of minimum gradient in the negative glow. Otherwise the theoretical curves fit the observations for different currents, and the various currents agree in furnishing the same value for the mobility of the positive ions. With wire cathodes the agreement between the theory and observations is practically perfect. The closeness with which the simple theory of localized ionization fits the results is strong evidence of an excessive degree of ionization in the negative glow as compared with that in the space toward the cathode. The results seem to indicate a condition similar to that exhibited by  $\alpha$ -rays, namely, increasing ionization with decreasing velocity. Assuming that the polarization region at the cathode is marked in extent by the cathode glow, the polarization p. d. is found to be proportional to the potential gradient per mean free path of the positive ions at their entrance to this region.

A. L. FEILD.

**The phenomena of fluorescence.** DESMOND GREGGHEGAN. *Chem. News* 117, 322 (1918).—A brief statement of commonly known facts, the conclusion being: "The phenomena of fluorescence arise from a diminution in the refrangibility of the ultraviolet rays which are ordinarily too refrangible to render them visible to the eye."

G. L. WENDT.

**The spectrum of cadmium in the inactive gases.** J. N. COLLIE AND H. E. WATSON. *Proc. Roy. Soc. London* 95A, 115–20(1918).—A preliminary report on the appearance of the spectra of electrode metals in discharges through the inactive gases. Cd was used because of its bright and broad spectrum but Zn, Mg, Pb and Bi act similarly. The brightest Cd lines appear in the spectrum of the gas in the cathode region even at relatively high gas pressures. Ne at 60 mm. pressure and He at 40 mm. showed some of the lines. The lines differ in brightness. Some are nearly always absent; some vary sharply with the pressure. It is difficult to obtain the lines at all in Kr while in Xe the electrodes melt. There was no obvious connection in the behavior of a line at different pressures or in different gases or of different lines in the same gas.

At one time there formed at the cathode a green ball of Cd vapor with a red tail 7 cm. long. This rotated slowly round the cathode with the tail pointing down the tube, and soon broke up. The Cd and A gases seemed to be separated. No explanation of the various phenomena is offered. The metallic spectrum appears with the feeblest currents when the tube and electrodes are quite cold. These phenomena are absent when diatomic gases are used.

G. L. WENDT.

**Measurements in the spectrum of molybdenum according to international normals.**

MARTHA PUHLMAN. *Z. wiss. Photochem.* 17, 97-131(1917); *J. Chem. Soc.* 114, II, 142.—Measurements were made with a large concave grating. Results in the region  $\lambda 2420$  to  $\lambda 4888$  are compared with those of Exner and Haschek. No evidence was found for constant frequency differences in certain pairs of lines, as suggested by Paulson.

G. L. WENDT.

**The arc spectrum of tungsten according to international units.** MARIA BELKE.

*Z. wiss. Photochem.* 17, 132-42, 145-68(1917); *J. Chem. Soc.* 114, II, 142.—The region  $\lambda 2249$  to  $\lambda 6984$  was measured and treated as in the preceding abstract, with the same conclusions.

G. L. WENDT.

**Arc spectrum of europium and of a new element between europium and samarium.**

J. M. EDER. *Sitzb. Akad. Wiss., Wien.* 126, 473-531(1917); *Science Abstracts* 21A, 264-5; cf. *C. A.* 11, 1081, 2637.—A table of the wave lengths and intensities of about 1200 lines from  $\lambda 7370$  to  $\lambda 2373$  is given. No evidence that Eu is anything but a simple element was obtained. In a Eu fraction containing Sa a no. of unknown lines were observed which seem to belong to an element lying between Eu and Sa, and for which the name euro-samarium is proposed. The lines, more than 200 in number, extend from  $\lambda 6300$  to  $\lambda 3260$ , being for the most part of low intensity. It is possible that they may belong to one of the rare earths whose spectrum has not been thoroughly investigated. The evidence, however, does not point to this conclusion. A Eu prepn. free from Sa did not give the new lines.

A. L. FEILD.

**Crystal structure of the alums and the role of the water of crystallization.** L.

VEGARD AND H. SCHJELDERUP. *Ann. Physik* 54, 146-64(1918); *Science Abstracts* 21A, 266.—By means of Bragg's  $\alpha$ -ray reflection method, measurements were made on the 4 following alums: ammonium alum, potassium alum, iron-ammonium alum, and chrome alum. A table is given of reflection angles and relative intensities, with the Rh line as a source of monochromatic X-radiation. The position of the  $H_2O$  groups and the complete structure of the crystal are shown by means of models. A very complex structure obtains in all cases.

A. L. FEILD.

**Theory of the thermionic amplifier.** H. J. VAN DER BIJL. *Phys. Rev.* 12, 171-98

(1918).—Theoretical treatment of the operation of the thermionic amplifier, together with a discussion of certain features of design. A voltage amplification of several hundred fold is not difficult to obtain, while a power amplification of several hundred fold was found possible when a plate voltage of only about 100 v. was used.

A. L. FEILD.

Radiation pattern of the transformation of magnesium hydroxide to magnesium oxide, etc. (V. D. LINGEN) 8. Coefficients of magnetization of oxygen and nitric oxide, and the theory of the magneton (BAUER, *et al*) 2.

#### 4. ELECTROCHEMISTRY.

COLIN G. FINK.

Surplus electric power after the war. J. W. BECKMAN. *Trans. Am. Electrochem. Soc.* 34 (advance copy); *Elec. Rev. West Elec.* 73, 735-6(1918); *Chem. Met. Eng.*

19, 613(1918).—A very important electrometallurgical development awaiting a successful solution is the direct manuf. of steel from iron ore. The other industry which would serve to help to consume elec. power after the war is the fertilizer industry. This includes the N-fixation industry and the elec. extn. of sol. phosphates from phosphate rock. The elec. method makes the phosphates completely sol. whereas by the old  $H_2SO_4$  method only a small % of P is rendered sol. C. G. F.

**The electric furnace after the war.** FRANCIS A. J. FITZGERALD. *Trans. Am. Electrochem. Soc.* 34 (advance copy); *Elec. Rev. West. Elec.* 73, 726-7(1918).—The induction type furnace did not develop as was expected, during the war, but the outlook for the future is very bright. The advantage of dispensing with the electrodes cannot be overlooked. Owing largely to the shortage of graphite crucibles and the consequent high expense involved, the development of the elec. furnace for brass has been greatly stimulated during the war and now there can be no question that elec. brass furnaces will be largely employed. The use of the elec. furnace greatly increased during the war and is bound to be still further extended after the war. Government ownership of hydroelectric systems is the most serious menace to the future of the elec. furnace so far as the larger developments are concerned. C. G. F.

**Performance and equipment of two-ton electric furnace.** ANON. *Elec. Rev. West. Elec.* 73, 747-8(1918); *Elec. Engineering* 52, No. 5, 12-3(1918).—The furnace, of the Heroult type, has a capacity of 2 tons. It is used for melting nichrome and high-nickel steel. The temp. of the furnace averages about  $2200^\circ$ . The primary side of the transformers is at 2200 volt, 60 cycle, 2 phase. There are 2 400-kva transformers. They are Scott connected so that they change the high-voltage 2-phase current into low-voltage 3-phase current, so as to have 1 phase for each of the 3 electrodes of the furnace. The power factor is from 85 to 90%. Full details are given and 6 cuts are shown. Cf. Easton, C. A. 12, 2068. C. G. F.

**Electric smelting of manganese ores.** ANON. *Elec. Engineering* 52, No. 5, 26(1918).—In 1917 115,000 tons of Mn ore containing more than 40% of metallic Mn were electrically smelted in U. S. compared with 27,000 in 1916 and 4,000 tons in 1913. C. G. F.

**Performance data on a brass-melting furnace.** A. S. WITMER. *Elec. World* 72, 891(1918).—Record of an 8-day run of a Baily furnace for brass melting. Energy per 100 lb. of brass poured, 12.7 kw. hr. Metal loss per 100 lb. of brass poured, 1.13 lb. The usual metal loss with oil-fired brass furnaces is 7 lb. With oil at 6 c. per gal., elec. energy at 1.5 c. per kw. hr. and metal at 20 c. per lb., the saving amounts to \$1.22 per 100 lbs. of metal poured. C. G. F.

**Federal nitrate plant (Cincinnati) power contract features.** ANON. *Elec. World* 72, 894(1918). C. G. F.

**The Zorzi system for the electrolytic production of hydrogen and oxygen.** G. CARRARA. *Elettrotecnica* 5, 86-90(1918); *Science Abstracts* 21B, 185.—The Zorzi cell is characterized by absence of diaphragms and by the peculiar shape of the electrodes. Each battery is formed of 16 Fe bells, open at the top, soldered to Fe bars and equally spaced. Each Fe bell is covered by a glass bell, also open at the top. A larger glass bell covers the column so as to lead the gas into a collector pipe. The gases developed at the surfaces of the Fe bells are immediately sent through the collector pipe to reduce to a minimum diffusion of one gas into the other. H and O collector pipes connect with trunk pipes which lead to gasometers. The electrolyte is a soda soln. (sp. gr. 1.17). The gases have a high degree of purity: 1.92% H in the O; 0.34% O in the H. The Zorzi cells are in successful operation at Varese.

W. H. BOYNTON.

**Storing direct-current aluminium arresters for the winter.** F. T. FORSTER. *Gen. Elec. Rev.* 21, 820-1 (1918).—When d. c. Al arresters are taken out of service the electrolyte should be poured into clean bottles and the Al plates washed in gasoline and then rinsed in clean warm water, after which they should be put back into the empty jar until again needed for service. This method is decidedly better than allowing the electrolyte to remain in the jars and applying a low voltage throughout the winter. Tests have shown that the Al film has the property of acquiring a critical voltage value corresponding to any voltage that is applied to it for a considerable length of time, provided this voltage is below the max. critical value. Detailed tests are tabulated and discussed. C. G. F.

**Experimental examination of the arc in gases under pressure.** W. MATHIESEN. *Electrician* 81, 451-3 (1918); see *C. A.* 12, 2069. C. G. F.

---

Synthetic nitrogen products (MORSELLI) 18. "Gasteam" plant (ANON.) 21.

---

**Storage battery.** B. FORD. U. S. 1,280,982, Oct. 8. Structural features.

**Electrolytic production of permanganates.** M. SCHOELD. U. S. 1,281,085, Oct. 8.  $\text{Na}_2\text{MnO}_4$  is converted into  $\text{NaMnO}_4$  by electrolysis and  $\text{KMnO}_4$  is then produced by reacting on the  $\text{NaMnO}_4$  with  $\text{K}_2\text{CO}_3$ . An electrolytic cell for use in the production of the permanganate is described.

**Electrolytic production of alkalis.** N. STATHAM. Brit. 118,355, Sept. 26, 1917. A diaphragm between an anode chamber and an empty cathode chamber allows passage of sufficient electrolyte to prevent back diffusion of  $\text{NaOH}$ . It may be faced on the discharge side with less porous material arranged so as to render the lower parts of the diaphragm less permeable than the upper parts. Uniform percolation throughout the diaphragm can thus be obtained. The body of the diaphragm may be of asbestos board or paper, and the facing of finer asbestos, incorporated with or applied to the body, and either stepped or steadily increasing in thickness downwards. Percolation takes place preferably at such a rate that, with concd. brine in the anode compartment, the cathode liquid may contain about equal proportions by wt. of alkali and salt, say 11 parts of the former to 10-11 parts of the latter. A direct overflow from the anode compartment of about 100 cc. of brine per sq. ft. of diaphragm surface may be provided for. The perforated cathodes may be sustained by perforated ribs on coverplates. Cf. 5,197, 1893, 20,889, 1903, and 27,830, 1907.

**Electrically fusing and depositing metals.** E. H. JONES. Brit. 116,308, Apr. 12, 1917. An arc electrode contains all the constituents requisite for the deposition of *high-speed steel*, and is covered with slag-forming material. *E. g.*, the electrode may consist of a mild-steel trough filled with a mixt. of 1.3 parts of C, 22 of W, 9 of Cr, and 0.25 of V, the Fe of the trough amtg. to 67.45 parts. In some cases, the steel only requires 6% of W. Mo may partly replace W, and other materials such as Ni and Co may be added. The whole is wound with asbestos yarn. Cutting parts of tools may be made or renewed by deposition from such an electrode; or the steel may be received by a mold at the bottom of which is the second electrode. Cf. 3,762, 1911 (*C. A.* 6, 2036), and 109,652 (*C. A.* 12, 123).

**Reducing iron ores.** H. A. GREAVES and H. ETCHILLS. Brit. 118,647, June 12, 1917. Gases given off in smelting Fe ores in an elec. furnace are passed through a rotary tube furnace through which the ores are passed on their way to the elec. smelting furnace. Details of construction and operation are specified.

**Alumina.** NORTON Co. Brit. 118,605, July 11, 1918.  $\text{Al}_2\text{O}_3$  is prepd. in fused condition from crude materials such as bauxite and clay by fusing the material with

an excess of C in an elec. furnace, sepg. the reduction products of the impurities, and then adding a solid oxidizing compd. to oxidize the partial reduction products of the  $\text{Al}_2\text{O}_3$ . As oxidizing agents,  $\text{Fe}_2\text{O}_3$ ,  $\text{SiO}_2$ , or  $\text{TiO}_2$  may be used, or crude bauxite or volatile materials such as  $\text{ZnO}$  or  $\text{Na}_2\text{CO}_3$ . An excess of the oxidizing substance may be employed, with or without some C, to reduce a part of the excess.

**Alumina.** NORTON CO. Brit. 118,606, July 11, 1918. In the fusion of  $\text{Al}_2\text{O}_3$  in an elec. furnace having a C hearth, the partial reduction of the lower layer of the charge is prevented by mixing with the lower layer small proportions, such as 5%, of a reducible material contg. O, such as  $\text{Fe}_2\text{O}_3$ , or, preferably, a material the products of reduction of which will be volatilized during the treatment, *e. g.*,  $\text{ZnO}$  or soda ash. When a volatile substance is added, the quantity may be considerably in excess of the amt. necessary to prevent reduction, so as to protect the  $\text{Al}_2\text{O}_3$  completely.

**Purifying drawn tungsten wire.** A. PACZ. U. S. 1,280,825, Oct. 8. Drawn W wire which has become associated with impurities such as C during its manuf. is heated to redness with air for a short time and afterward heated for some time at a white heat, in an atm. of N 88 and H 12%, to reduce oxides formed during the heating in air. The method is especially adapted for treating W previously treated to render it "non-off-setting."

**Tungsten filaments.** C. T. FULLER. U. S. 1,280,704, Oct. 8. W filaments which have been formed by ordinary mechanical drawing are heated at least to redness in an oxidizing atm., after which they may be heated to a higher temp. *in vacuo* or in an inert gas to increase their ductility and pliability and improve their capacity for retaining these properties during use in incandescent lamps. The process is especially adapted for the treatment of "non-off-setting" filaments.

## 6. INORGANIC CHEMISTRY.

H. I. SCHLESINGER.

**Observations on the rare earths. VIII. Separation of yttrium from erbium; the ratio  $\text{Er}_2\text{O}_3 : 2\text{ErCl}_3$ .** E. WICHERS, B. S. HOPKINS AND C. W. BALKE. *J. Am. Chem. Soc.* 40, 1615-9(1918); cf. *C. A.* 11, 237; 12, 1156, 1157, 2072.—A comparative study was made of newer methods for sepg. Y and Er using material of at. wt. 108.5 free from other rare earths. Both the cobalticyanide and nitrite pptn. methods gave good results, but the classic nitrate fusion method gave far superior results. Er material of high purity was prepd. by this method. The ratio  $\text{Er}_2\text{O}_3 : 2\text{ErCl}_3$  was found to vary with the temp. and length of ignition of the oxide.  $\text{Er}_2\text{O}_3$  prepd. by ignition of the oxalate and ignited for several hrs. at nearly  $800^\circ$  and 2 hrs. at nearly  $900^\circ$  was found to retain  $\text{CO}_2$ . This is contrary to Hofmann (*C. A.* 5, 254) and brings into dispute the accepted at. wt.

A. R. M.

**Preparation and properties of yttrium mixed metal.** J. F. G. HICKS. *J. Am. Chem. Soc.* 40, 1619-26(1918).—The "mixed metal" was prepd. by decompn. of the anhydrous chlorides *in vacuo* by Na and by electrolysis of the fused chlorides. Electrolysis of the soln. of the oxides in fused cryolite was less efficient. Loss of  $\text{YtCl}_3$  by volatilization was demonstrated. The metal was obtained in coherent form by sintering the metal powder *in vacuo*. The sintered metal was blue-gray, of low luster, soon tarnished by air, decompd. warm water rather rapidly, and reacted violently with dil. acids. The metal disintegrated in time to a powder, especially if exposed to air. These properties made impossible a satisfactory metallographic study. A. R. MIDDLETON.

**Zirconyl basic chromate.** F. P. VENABLE AND L. V. GILES. *J. Am. Chem. Soc.* 40, 1653-6(1918).—Soln. of  $\text{Zr}(\text{OH})_4$  in hot dil. soln. of  $\text{CrO}_3$  followed by diln. and

boiling gives a yellow ppt. approx.  $2\text{ZrO}(\text{OH})_2 \cdot \text{ZrO} \cdot \text{CrO}_3 \cdot 8\text{H}_2\text{O}$ . The results appear to controvert Haber (*Monatsh.* 18, 667(1897)).

A. R. MIDDLETON.

**Scandium from a Brazilian source.** C. JAMES. *J. Am. Chem. Soc.* 40, 1674 (1918).—Sc was conclusively identified in Brazilian  $\text{ZrO}_2$ . Other Zr minerals will be investigated.

A. R. MIDDLETON.

**Basic carbonates of copper.** H. B. DUNNICLIFF AND S. LAL. *J. Chem. Soc.* 113, 718–22(1918).—In 13 samples of com. Cu carbonate CuO was found to vary from 66.16 to 78.60%, controverting the statement of Pickering (*C. A.* 4, 29) that com. carbonate has a formula identical with that of malachite in which  $\text{CuO} = 71.94\%$ . The low values were proved not due to adsorption of water. Five samples containing  $\text{CuO} = 69.55\text{--}71.71\%$  were found to contain  $\text{CO}_2 = 17.35\text{--}18.1\%$ , much below the requirement for malachite or azurite. It is concluded that the com. carbonate is a mixt. of very varying compn. Attempts to prep. a carbonate of definite compn. gave products in which CuO varied from 71.08 to 78.85% according to conditions of prepn. By maintaining definite conditions products of nearly the same compn. were obtained and these approximated closely to  $2\text{CuCO}_3 \cdot 5\text{Cu}(\text{OH})_2$  or  $7\text{CuO} \cdot 2\text{CO}_2 \cdot 5\text{H}_2\text{O}$ .

A. R. MIDDLETON.

**The equilibrium between carbon monoxide, carbon dioxide, sulfur dioxide and free sulfur.** J. B. FERGUSON. *J. Am. Chem. Soc.* 40, 1626–44(1918).—A careful study is made in this paper of the reaction  $\text{CO} + \frac{1}{2}\text{SO}_2 \rightleftharpoons \text{CO}_2 + \frac{1}{2}\text{S}_2$ . The latter two products are formed between  $1000^\circ$  and  $1200^\circ$  together with possibly traces of COS in mixtures rich in CO. Equil. constants for these temps. have been detd. from which calcns. are made for the constants up to  $1500^\circ$  with the aid of the free-energy equation of the reaction and of  $\text{SO}_2$  from its elements. A semi-stream method is found to avoid errors in the original stream method. App., including a *constant-temp. elec. resistance furnace*, and methods of analysis of the mixed gases are fully described.

G. L. CLARK.

Crystal structure of the alums and the role of the water of crystallization (VEGARD, SCHJELDERUP) 3.

## 7. ANALYTICAL CHEMISTRY.

E. G. R. ARDAGH.

**The quantitative analysis of small quantities of gases.** H. M. RYDER. *J. Am. Chem. Soc.* 40, 1656–62(1918).—This method involves the freezing out of  $\text{CO}_2$  and  $\text{H}_2\text{O}$  vapor by means of liquid air and solid  $\text{CO}_2$ , addition of O and combustion of the dry gases remaining, and redetn. of  $\text{CO}_2$  and  $\text{H}_2\text{O}$  vapor. By it  $\text{H}_2\text{O}$ ,  $\text{CO}_2$ , CO, O, H, N and  $\text{CH}_4$  can be detd., but not O and  $\text{CH}_4$  in presence of each other. When the total amt. of sample was less than 5 cu. mm., an av. analysis shows a max. error of 6% in the element present in the greatest quantity. Much greater accuracy is obtained with larger quantities.

IRENE F. SMITH.

**Simple method for determining sulfur dioxide.** G. W. JONES, J. H. CAPPS AND S. H. KATZ. *Mining Sci. Press* 117, 415–8(1918).—The authors describe in detail, with graphs and an illustration, a method and app. for detg.  $\text{SO}_2$  by I titration for the use of engineers working in the field. The app. is strong, cheap, easily replaceable, and assembled into a case designed for portability. The method is not accurate beyond 2 significant figures, but has a range of about 10 parts per mil. by vol. to 1% or more. With the aid of a table giving the effect upon the senses of varying concns. of  $\text{SO}_2$ , it is possible to est. the small proportions of  $\text{SO}_2$  without analysis. Cf. WELLS *et al.*, *C. A.* 10, 436.

F. W. SMITHER.

**Zirconium content in ores and alloys.** J. D. FERGUSON. Detroit. *Eng. Mining J.* 106, 793-4(1918); cf. *C. A.* 12, 2075.—The procedure for Zr steel differs from that described in the previous paper in the following details: After dissolving in HCl and  $\text{HNO}_3$ , add 6 cc. of  $\text{H}_2\text{SO}_4$  before evapg. After washing the  $\text{SiO}_2$  ppt. with hot  $\text{H}_2\text{O}$ , wash with HCl (1:1) and then again with hot  $\text{H}_2\text{O}$ . Instead of weighing the ppt. after ignition, treat directly with  $\text{H}_2\text{SO}_4$  and HF; evap. only to the appearance of  $\text{SO}_2$  fumes, dil. the residue and add to the main filtrate. Treat with 6 cc. of  $\text{NH}_4\text{HSO}_4$  soln. instead of  $\text{Na}_2\text{S}_2\text{O}_3$ ; cool, and neutralize with  $\text{NH}_4\text{OH}$  (1:1). Acidify with 10 drops of concd. HCl if the Zr is to be pptd. with  $\text{PhNHNH}_2$ , or with 2 cc. of concd.  $\text{H}_2\text{SO}_4$  if it is to be pptd. as phosphate. For the former, add 1 cc. of  $\text{PhNHNH}_2$  per 100 cc., boil, let stand 30 min., filter and wash with hot  $\text{H}_2\text{O}$ . Redissolve the ppt. in hot dil. HCl and  $\text{H}_2\text{SO}_4$ , reduce with 1 cc. of  $\text{NH}_4\text{HSO}_3$ , neutralize and proceed as before. This frees the Zr and Al from Fe. The final sepn. can be made by fusing with  $\text{Na}_2\text{CO}_3$ , filtering, igniting the insol.  $\text{Na}_2\text{ZrO}_4$  and fusing it with  $\text{K}_2\text{S}_2\text{O}_7$ , dissolving and pptg. as  $\text{Zr}(\text{OH})_4$ . It is then ignited and weighed as  $\text{ZrO}_2$ . Or the sepn. can be effected by the use of "cupferron" as follows: Dissolve the hydroxides in 40 cc. of hot HCl (1:1), dil. to 100 cc., cool and add a 6% soln. of cupferron till the Zr is pptd., then in excess ( $1\frac{1}{2}$  the total vol.). Let stand 15 min., filter, wash with cold dil. HCl (1:5), followed by  $\text{H}_2\text{O}$ ,  $\text{NH}_4\text{OH}$  and again by  $\text{H}_2\text{O}$ . Ignite and weigh as  $\text{ZrO}_2$ . The  $\text{PhNHNH}_2$  and phosphate methods agree very closely, generally within 0.05%. IRENE F. SMITH.

**The determination of tin in high grade wolfram ores and the use of lead as a reducing agent in Pearce's assay.** A. R. POWELL. *J. Soc. Chem. Ind.* 37, 285-87(1918).—The aqua regia method of detg. Sn in wolfram ores gives good results but is slow, as are also the method of fusion with KCN and the sepn. by means of Na tungstate and stannate. P.'s method is not only rapid but also gives good results. He fuses the ore with bisulfate, adds tartaric acid, filters and fuses the ppt. with  $\text{Na}_2\text{O}_2$ . The presence of Cu, Bi or Mo necessitates previous treatment of the ore with  $\text{HNO}_3$ . Instead of reducing the  $\text{SnCl}_4$  soln. with Fe and titrating with I, P. reduces with Pb which gives a more accurate end point, due to yielding a colorless soln. after reduction. I. F. S.

**The spectroscopic determination of lead in copper.** C. W. HILL AND G. P. LUCKEY. *Bull. Am. Inst. Mining Eng.* 142, 1581-92(1918).—The present paper deals with the development of the previously reported method (*C. A.* 12, 31) in the factory, giving the details of app. and its standardization, and presenting a comparison of the accuracy of the method with that of the standard electrolytic detn. The advantages claimed are facility and accuracy. The analyses can be made in the refining plant by the foreman, and the process of refining can be followed rapidly, without holding the furnace for a chem. analysis. Illustrations, curves, and tables are given. F. W. SMITHER.

**The iodometric determination of copper.** I. M. KOLTHOFF. Utrecht. *Pharm. Weekblad* 55, 1338-46(1918).—It was found by Moser (*Z. anal. Chem.* 43, 597-616 (1904)) that in the de Haen titration of Cu with KI, the results are too low if the soln. is acidified with HCl instead of  $\text{H}_2\text{SO}_4$ . This he ascribed to the soly. of CuI in HCl; but K. considers it much more probable that the effect is due to formation of complex compds. of the  $\text{Cu}^{++}$  ion with HCl. Expts. showed that the soln. can be titrated immediately after adding KI. The same results are obtained in neutral as in acid soln., but the titration is much slower. Dilg. the soln. does not affect the results; but, as in neutral soln., the titration is slower. In the KCNS modification, the manner of adding the reagents is important; if KI and KCNS are added to a neutral soln. of  $\text{CuSO}_4$ , the liberated I oxidizes some KCNS to HCN and  $\text{H}_2\text{SO}_4$ , causing low results. But if the KI and acid are added before the KCNS, and the soln. is then titrated at once, this error is avoided. Either HCl or  $\text{H}_2\text{SO}_4$  may then be used. The larger the amt. of KCNS, the more rapid is the titration; but if much is present, a slight error is introduced

owing to lessened sensitivity of the starch iodide reaction. For greatest rapidity, the soln. should be very dil. and should contain about 20 cc. of 25% KCNS soln. per cc. of  $N$  KI used. A correction of 0.05 cc. of 0.1  $N$   $Na_2S_2O_3$  should then be added. This method gives excellent results in sugar detns., and is much cheaper than the old method without KCNS. It can be used to advantage to det. sugar in milk directly, without prepg. the serum. Neither the old method nor the KCNS modification is applicable in the presence of Fe; but this, if present as  $Fe^{+++}$ , can be rendered harmless by adding  $Na_2P_2O_7$ . Or, addition of NaF causes the formation of  $Na_3FeF_6$ , in which form Fe does not liberate I. The titration can then be carried out as usual.

JULIAN F. SMITH.

**Volumetric estimation of zinc by acidimetric titration.** R. HOWDEN. *Chem. News* 117, 322(1918).—The Zn should be present as  $ZnCl_2$ , and the soln. should be free from salts of other heavy metals or  $NH_4$ . Evap. to small vol. (to expel free acid), dil. to 20 cc., add 1 drop of Me-orange soln. and carefully neutralize with 0.1  $N$  NaOH soln. Add a few drops of phenolphthalein soln. and titrate the combined acid with 0.1  $N$  NaOH soln. The end-point is indicated by a pink color which does not disappear on boiling the soln. Standardize the NaOH against a soln. of known concn. prepd. from pure Zn. The  $Zn(OH)_2$  ppt. does not interfere. "Expt. shows that absolutely concordant results can be obtained." No results are reported. F. W. SMITHER.

**Analysis of commercial zinc.** L. BERTIAUX. *Ann. chim. anal.* 23, 161-9, 181-91 (1918).—A detailed account, with illustrations of app., of the methods used in the lab. of the French Metals Co. **Sampling:** Use the largest no. of slabs practicable, boring completely through each, grinding the borings in a bronze mortar, and then mixing; or, saw through each slab and pass a magnet over the sawings. The final sample weighs 500 to 700 g. **B.** gives tables showing the irregularities (segregation) of the Pb content of 2 lots of Zn. **Detn. of Pb:** Treat 10 g. of the sample with 100 cc.  $Cu(NO_3)_2$  (made by treating 100 g. of pure electrolytic Cu with 500 cc. of 36° Bé.  $HNO_3$  and dilg. to 1 l.), 100 cc.  $H_2O$ , and 62 cc.  $HNO_3$  (36° Bé.); boil a min. to expel nitrous vapors, dil. to 300-350 cc., and electrolyze with a current of 0.3 amp. **Detn. of Fe:** In a 500-600-cc. erlenmeyer treat 25 to 50 g. of the metal (previously tested with a magnet) with concd.  $H_2SO_4$  (1 cc. for each g. of sample + an excess of 5 cc.), dilg. progressively to  $\frac{1}{8}$  strength. When the action abates (if too slow, add 2 drops of 50%  $NiSO_4$  soln.), heat till all dissolves, then boil a few min.; cool, filter through a wad of cotton, wash, and titrate with  $KMnO_4$  (1 cc. = 0.001 g. Fe). This gives the approx. amt. of Fe; if this exceeds 0.002, dil. to a known vol., transfer an aliquot containing not over 0.002 g. Fe to a cylinder, add 2 cc.  $HNO_3$  (36° Bé.), then 30 cc. of  $NH_4CNS$ , dil. to 500 cc. and det. Fe colorimetrically. **Tin:** To 50 g. of the Zn in a 600-cc. beaker add 60 cc.  $H_2O$ , then portionwise 191 cc.  $HNO_3$  (36° Bé.), warm, dil. to 450-500 cc. with boiling  $H_2O$ ; add several cc. of  $NH_4NO_3$  soln., boil several min., let settle (no turbidity indicates absence of Sn); filter, wash with hot 10%  $HNO_3$  till Zn-free, then with hot  $H_2O$ , ignite, and weigh as  $SnO_2$  (may contain Sb), and use factor 0.76 for Sn (theory = 0.7881). For an exact detn., fuse the  $SnO_2$  in a porcelain crucible with  $Na_2CO_3$  + S, cool, dissolve in warm  $H_2O$ , filter, and wash with  $H_2O$  + a few drops of  $Na_2S$  soln. To the filtrate and washings, add 10 cc. of 50%  $(NH_4)_2SO_4$  soln., evap. to dryness, take up with  $HNO_3$  and 5 cc. of  $H_2SO_4$  (1:2); evap. again to dryness to eliminate the S. Let cool, add  $H_2O$ , then 4 cc. HCl and 20 g. of  $(NH_4)_2C_2O_4$ ; warm to dissolve, dil. to 200 cc. and pass a current of  $H_2S$  for 1.5 hrs. through the nearly boiling soln. Filter rapidly on a filter impregnated with  $(NH_4)_2SO_4$ , and wash with hot  $H_2O$  (+  $H_2S$  and  $(NH_4)_2SO_4$ ). Heat the filtrate to expel  $H_2S$ , oxidizing the last traces with  $H_2O_2$ ; add 20 cc. concd. HCl, then 10 g. of  $(NH_4)_2C_2O_4$ , dil. to 300-350 cc., and electrolyze at about 40° with a current of 1 to 2 amp. In the presence of Sb the Sn may be sepd. in the detn.

of Cd. *Copper*: Treat 10 g. of Zn with 100 cc.  $H_2O$ , 15 cc. concd.  $H_2SO_4$ , and 25 cc.  $HNO_3$  ( $36^\circ B\acute{e}$ .), finally warming; dil. to 300–350 cc. and electrolyze (1 amp.). With very small amts. of Cu, after washing the deposit, redissolve in a little  $HNO_3$ , evap., add  $H_2O$  and  $NH_4OH$ , and det. colorimetrically. *Cadmium*: In a 700–800 cc. erlenmeyer, attack 25 to 50 g. of the sample with concd.  $H_2SO_4$  (1 cc. per g. of Zn + 15 cc. excess), dilg. progressively to  $\frac{1}{4}$  strength (adding previously, if necessary, 2 or 3 drops of 50%  $NiSO_4$  soln.); boil to complete soln. of the Sn (a residue of metallic Pb and Cd remains). Dil. to 500 cc., pass  $H_2S$  through for 30 min., filter, wash with satd.  $H_2S$  soln. containing 3% by vol. of concd.  $H_2SO_4$  to remove Zn (if Sn is to be detd. at this stage, treat the ppt. with warm  $NH_4HS$ , wash with satd.  $H_2S$  soln.; evap. the filtrate and washings to dryness in porcelain on a sand bath, take up with concd.  $HNO_3$ , add 5 cc.  $H_2SO_4$  (1:2), evap. again, and proceed as under Sn above). Dissolve the impure CdS in boiling  $HNO_3$  (1:2), then aqua regia, boil, and add hot  $H_2O$ , receiving the solns. in a porcelain dish; add 5 cc.  $H_2SO_4$ , evap. on sand bath until all  $SO_3$  fumes are expelled, take up with a measured amt. of  $H_2SO_4$  (1:10), heat to dissolve sol. sulfates; filter, wash with a known vol. of  $H_2SO_4$  (1:10); dil. the filtrate and washings to a content of 3%  $H_2SO_4$  by vol., pass  $H_2S$  through for 30 min. (the CdS will contain Cu, As, Sb, and Sn sulfides, unless the 3 latter were removed as above). Filter, wash with 3% (by vol.)  $H_2SO_4$ , then with  $H_2S$  water; treat the ppt. on the filter and in the pptg. vessel with a mixt. of 20 cc. of  $NH_4HS$  + 20 cc. of 20% KCN soln., then with  $H_2S$  water to remove KCN. Redissolve in hot  $HNO_3$  (1:2), then with hot aqua regia (1:2), and wash with boiling  $H_2O$ . Add to the united solns. 5 cc.  $H_2SO_4$  (1:2), evap. on sand bath until  $SO_3$  fumes disappear, cool; add  $H_2O$ , warm to complete soln., neutralize with NaOH soln., add 40 cc. of an 18% alc. NaOH soln., then 40 cc. of 20% KCN soln., dil. to 300 cc. and electrolyze (0.4 amp.). *Arsenic*: To 25 g. of the Zn (covered with  $H_2O$ ), in a l. casserole covered with a funnel, add portionwise 102 cc.  $HNO_3$  ( $36^\circ B\acute{e}$ .); after action ceases, add 31 cc. concd.  $H_2SO_4$ ; mix, evap. on sand bath to complete disappearance of  $SO_3$  fumes. Transfer the dry sulfates to a flask, add 15 g. of  $FeSO_4 \cdot 7H_2O$ , then 150 cc. concd. HCl and distil  $AsCl_3$  in the usual manner. Neutralize the distillate with satd.  $Na_2CO_3$  soln., acidify with HCl, add  $NaHCO_3$ , and titrate with I soln., using 5 cc. of a 1% starch soln. as indicator. Or, transfer the distillate to a flask, dil. to 250 cc. with  $H_2O$  and titrate cold with  $KBrO_3$  soln. (0.7427 g. per l.; 1 cc. = 0.001 g. As) until methyl orange (2 drops of 1% soln.) is decolorized. *Antimony*: Transfer the residue in the distn. flask from the As detn. to a round-bottom l. flask, add 250 cc.  $ZnCl_2$  soln. (d. 2.0) and 5 g. of  $(CO_2H)_2$  and distil  $SbCl_3$  in a current of  $CO_2$ . Neutralize the distillate with  $NH_4OH$ , acidify slightly with dil.  $H_2SO_4$ , pass in a current of  $H_2S$ ; filter, wash with satd.  $H_2S$  soln.; dissolve the  $Sb_2S_3$  in NaHS soln. (d. 1.22–1.225), wash 2 or 3 times with tepid NaHS soln. Add 20 cc. of 20% KCN soln., mix, and electrolyze (0.5 amp.). *Sulfur*: Det. by evolution method, treating 20 g. of the Zn with 200 cc.  $H_2SO_4$  (1:10) and 25 cc. HCl and absorbing the  $H_2S$  in ammoniacal  $AgNO_3$  soln. (10 cc. of a  $AgNO_3$  soln. containing 10 g. Ag per l. + 25 cc.  $NH_4OH$  of  $22^\circ B\acute{e}$ ., dild. to 50 cc. with  $H_2O$ ). A current of  $CO_2$  is passed through the system during the operation. Filter off the  $Ag_2S$ , wash with  $H_2O$  +  $NH_4OH$ , ignite, and weigh;  $Ag \times 0.1481 = S$ . *Carbon*: Use 5 g. of sample. Det. by  $CrO_3$ - $H_2SO_4$  wet combustion method, using the app. previously described (cf. C. A. 8, 35), except slightly moist granulated KOH is used as an absorbent. Tables are given showing the analyses of several varieties of French and American Zn.

F. W. SMYTH.

The evaluation of zinc dust: a proposed method of analysis. L. A. WILSON. *Chem. Met. Eng.* 19, 32–4 (1918).—A modification of the Meyer method (SCOTT, "Standard Methods of Chemical Analysis." The chief departures are the use of strong acid and the addition of  $FeSO_4$  and a small piece of sheet Pt, the latter 2 acting as catalysts. To

simplify calcn., a correction tube of dry H over Hg, inverted in a cylinder of Hg, can be used. After detg. the vol. of H in this tube, pure  $H_2O$  is let in and the vol. read again at equil. The % of metallic Zn is then  $(V_D \times V_s \times 0.29196) / V_d$ , where  $V_D$  is vol. of gas evolved in the detn.,  $V_s$  is vol. of dry H in the correction tube at standard conditions, and  $V_d$  is the vol. of the same H over  $H_2O$ , read under the same conditions as the H evolved. The factor is due to the fact that the vapor pressure of  $H_2O$  over 10%  $H_2SO_4$  is lower than over pure  $H_2O$ .

IRENE F. SMITH.

**Rapid method of estimating phosphorus in bronzes.** T. E. ROONEY. *Inst. Metals*, Sept. 11, 1918; *Engineering* 106, 332 (1918).—Dissolve in a 600-cc. erlenmeyer 0.5 to 2 g. of bronze in a mixt. of 20 cc. concd.  $HNO_3$  and 10 cc. concd.  $HCl$  (or 60 cc.  $HNO_3$  (d. 1.135) + 10 cc. concd.  $HCl$ ), and heat, without boiling, until most of the red fumes have been evolved. (If the concd. acids are used dil. to about 70 cc.) Cool, add slowly with const. shaking 40 cc.  $NH_4OH$  (d. 0.96), then 35 cc. of molybdate soln., and shake well for a few min. Let stand until the ppt. settles out (1 to 2 hrs.), filter on pulp, wash acid-free with  $H_2O$ , transfer the filter and ppt. to the flask, add excess of 0.05 N  $NaOH$  soln. and titrate back with 0.05 N  $H_2SO_4$ , using phenolphthalein as indicator. *Notes:* The digestion with acid must be long enough to oxidize all the P, or the results will be low. Boiling or heating must not be too prolonged or Sn will be pptd. and will be difficult to redissolve. A table is given showing the compn. of com. bronzes and the results obtained by the above volumetric method and the usual gravimetric method. The results by the 2 methods show excellent agreement. F. W. SMITHER.

**A method for the colorimetric estimation of cobalt.** E. G. JONES. Univ. Liverpool. *Analyst* 43, 317-9 (1918).—It is possible to est. 0.01-0.1% Co in materials such as varnish and ZnO-paints. Incinerate a weighed quantity of varnish in a porcelain crucible and ext. the ash with concd.  $HCl$ . If any insol. matter remains, add aqua regia followed by  $HCl$  to remove  $HNO_3$ . Evaporate to dryness, dissolve in hot  $H_2O$  with the addition of a few drops dil.  $HCl$  and dil. the soln. to a convenient vol. Transfer an aliquot to a Nessler cylinder, add 5 cc.  $NH_4$  citrate (dissolve 500 g. citric acid in 250 cc.  $H_2O$  and add 500 cc.  $NH_4OH$  (d. 0.880); this is not a neutral soln., but contains excess  $NH_3$ ). Dil. the mixt. nearly to 100 cc., add 5 cc.  $\alpha$ -nitroso- $\beta$ -naphthol soln. as prepared by Attack (*J. Soc. Chem. Ind.* 34, 641-3; *C. A.* 9, 2363). Mix the contents of the cylinder, then match against different amts. of standard soln. of Co to which have been added the same amts. of  $NH_4$  citrate and  $\alpha$ -nitroso- $\beta$ -naphthol as used with the sample. The amts. of free  $NH_3$  should be nearly the same in all solns. compared. The most satisfactory amt. of Co for comparison is about 0.1 mg. Varnishes to which were added the following % amts. of Co: 0.0095, 0.039, 0.066, 0.072, 0.0104, 0.180, showed 0.009, 0.037, 0.062, 0.070, 0.103 and 0.178, resp. The mineral matter in these consisted mainly of  $Fe_2O_3$  with traces of  $SiO_2$  and Pb and sometimes minute traces of Cu and Mn. Modifications are necessary in presence of Cu (except in minute traces of Ni or of Mn). Remove Cu by  $H_2S$ , having the acidity of the soln. about 0.05 N with  $HCl$ . Filter, and remove excess  $H_2S$  from the filtrate by boiling. There is serious interference caused by Ni unless the amt. present is much smaller than that of Co. Add a few cc.  $NH_4$  citrate soln. to the neutral or slightly acid soln., dil. to about 100 cc. with  $H_2O$  and heat nearly to boiling. Add 1% soln. dimethylglyoxime ( $EtOH$  soln.), about 1 cc. for every 2 mg. Ni, then  $NH_4OH$  drop by drop until slightly alkaline. Stir, allow to stand 5 min. in a warm place, filter and wash with hot  $H_2O$ . Dil. the filtrate to a convenient vol., transfer an aliquot to a porcelain dish, evap. to dryness and gently ignite. Treat the residue first with aqua regia, then with concd.  $HCl$ , and evap. to dryness. Add a drop of dil.  $HCl$ , ext. with  $H_2O$  and det. Co in the usual way. If the amt. of Mn present is very considerably greater than that of Co, it must be removed, not necessarily completely, but in greater part. To the soln. contg.

the metals as chlorides, add about an equal vol. of  $\text{HNO}_3$  (d. 1.2), and a small quantity of sodium bismuthate. Digest on a hot plate until the permanganate color disappears and the Mn is pptd. Filter, make up to a suitable vol., transfer an aliquot to a Nessler cylinder. Add 5 cc. neutral  $\text{NH}_4$  citrate, neutralize the liquid with  $\text{NH}_4\text{OH}$  (litmus) and add a measured quantity of  $\text{NH}_4\text{OH}$  (about 10%  $\text{NH}_3$ ). Match the color against a standard Co soln. to which has been added the same amts. of neutral  $\text{NH}_4$  citrate,  $\text{NH}_4\text{OH}$  and  $\alpha$ -nitroso- $\beta$ -naphthol. The procedure for ZnO-paints is similar to that employed for varnishes. Specimens to which were added 0.063 and 0.114% Co, resp., showed 0.063 and 0.103% by this method. H. M. LANCASTER.

**Determination of chromic oxide in chromite.** W. C. RIDDELL AND E. KITTRIDGE. *Mining Sci. Press* 117, 558-9(1918).—Based on exptl. data reported, the following method was developed for the rapid detn. of  $\text{Cr}_2\text{O}_3$  in ores and mill products submitted for analysis in connection with the War Minerals Investigation, being conducted by the U. S. Bureau of Mines. Transfer 0.5 g. of the ore (100-mesh) to a 20-cc. spun-Fe crucible containing 4 to 5 g. of  $\text{Na}_2\text{O}_2$ , mix thoroughly by stirring with a glass rod, cover with a little  $\text{Na}_2\text{O}_2$ , and fuse at a red heat. After the charge has melted, it should remain in the molten condition for 5 min. Let cool, place in a 400-600-cc. beaker, add about 100 cc. of  $\text{H}_2\text{O}$  and digest until the fused mass has disintegrated, after which remove and rinse the crucible; boil for at least 5 min. to decompose the  $\text{Na}_2\text{O}_2$ ; without filtering, neutralize the soln. with  $\text{H}_2\text{SO}_4$  (1:4) and add 25 to 30 cc. excess. Dil. to 300 to 400 cc. with cold  $\text{H}_2\text{O}$ , add about 0.2 N  $\text{FeSO}_4$  soln. in slight excess and titrate back with 0.2 N  $\text{K}_2\text{Cr}_2\text{O}_7$  soln., using  $\text{K}_2\text{Fe}(\text{CN})_6$  as an outside indicator. About 40 detns. can be run in 8 hrs. When Fe, as well as Cr, is to be detd. a heavy 20-cc. porcelain crucible should be used. When the fusion is made over a burner, the crucible should be covered and care exercised to avoid spattering; with a muffle, no cover is necessary. F. W. SMITH.

**Determination of nitrates in caliche and its products.** J. E. CLENNELL. *Eng. Mining J.* 106, 660-3(1918).—A modification of the Pelouze method for the detn. of nitrate in caliche is described. The author finds that  $\text{FeSO}_4$  is not easily oxidized by the atm., as is commonly supposed. Prolonged boiling of caliche with  $\text{FeSO}_4$  does not completely oxidize the  $\text{Fe}^+$  to  $\text{Fe}^{++}$  unless the mixt. contains a considerable concn. of  $\text{H}_2\text{SO}_4$ . When chlorides are present in the caliche, they also are reduced, causing high results. They also reduce  $\text{KMnO}_4$  in the final titration unless the decomposed sample is sufficiently dild. A standard soln. of  $\text{FeSO}_4$  with the necessary amt. of free  $\text{H}_2\text{SO}_4$  does not keep owing to the formation of an insol. ppt. C. advises a soln. only slightly acidified. Since the boiling cannot be hurried, a detn. requires about 45 min. IRENE F. SMITH.

**The determination of hypochlorites and chlorates in presence of each other.** I. M. KOLTHOFF. *Utrecht. Pharm. Weekblad* 55, 1289-95(1918).—In detg.  $\text{HOCl}$  by oxidation of  $\text{As}_2\text{O}_3$ , the drop test on KI-starch paper can be avoided by direct use of indigo, or better still, methyl red in the acid soln. The titration can be carried out in either  $\text{HOAc}$  or  $\text{HCl}$  soln., without any interference by chlorates. Contrary to the  $\text{HOCl}$  detn., indigo is a better indicator than methyl red for titrating chlorates. The best procedure is to add 10 cc. of 39%  $\text{HCl}$  and 10 cc. of sample to 25 cc. of 0.1 N  $\text{As}_2\text{O}_3$ , boil gently for 5 min., and titrate the excess of  $\text{As}_2\text{O}_3$  with 0.1 N  $\text{KBrO}_3$ . In com. bleaching powder, low available Cl is more often due to faulty packing or shipping, allowing the material to get wet, than to fraudulent adulteration. This can usually be decided by detg. both the hypochlorite and the chlorate content before shipping and after receiving. The loss of available Cl will appear as increase of chlorate. The strength of Cl water is readily detd. by the method described above for hypochlorites. JULIAN F. SMITH.

The separation of germanium from arsenic by the distillation of the chloride in the presence of a chromate. P. E. BROWNING AND S. E. SCOTT. *Am. J. Sci.* 46, 663-5(1918).—A modification of the method previously reported (*C. A.* 11, 3190). The distn. flask consisted of a 75-cc. Pyrex Erlenmeyer beaker fitted with a 2-hole rubber stopper; through one opening was inserted a bent glass tube, the other end of which dipped just below the surface of 3 cc. of  $H_2O$  in a test tube immersed in ice- $H_2O$ ; through the second opening another tube was inserted so as to have its end about 1 cm. below the surface of the liquid to be distd. This tube is connected through a wash bottle with a  $CO_2$  generator. Place the mixt. to be distd. in the flask, add 5 cc. of 10%  $K_2Cr_2O_7$  soln. and a few drops of  $H_2SO_4$ ; warm about 1 min., add 10 cc. concd.  $HCl$ , and distil in a current of  $Cl_2$  to about half its vol.; cool in  $CO_2$ , and ppt.  $GeS_2$  in the distillate with  $H_2S$ . Exptl. results reported show that 0.0005 g.  $GeO_2$  can be readily detected when present with 0.1 g.  $As_2O_3$ .  
F. W. SMITHER.

Separating barium from strontium. J. WADDELL. *Mining Sci. Press* 117, 495-6 (1918).—To 50 cc. of the neutral soln. (equiv. to 0.3 g. of  $BaCl_2 \cdot 2H_2O$ ) in an erlenmeyer, add 10 cc. 30%  $AcONH_4$  soln., heat to boiling, and, while giving the flask a swirling motion, add 5 cc. 10%  $(NH_4)_2Cr_2O_7$  soln. Boil for 1 min., cool, filter through a Gooch crucible, and wash with cold  $H_2O$  + a few drops of the  $AcONH_4$  soln. Dissolve the ppt. by pouring through the crucible as little hot 1:1  $HNO_3$  as will serve the purpose, alternating with hot  $H_2O$ , and receiving the solns. in the original erlenmeyer; wash free of acid, dil. to about 50 cc., and heat to boiling. Add dil.  $NH_4OH$  until a permanent but not abundant ppt. forms, then add 10 cc. 30%  $AcONH_4$  soln. and 5 cc. 10%  $(NH_4)_2Cr_2O_7$  soln.; boil for about 1 min., cool, and filter as described. Dissolve the  $BaCrO_4$  in cold dil.  $HCl$  and det. Ba volumetrically as previously described (*C. A.* 12, 1445). In the sepn. of Ba from Sr in barite, if the amt. of Sr is known to be small one pptn. suffices. Cf. *C. A.* 12, 2175.  
F. W. SMITHER.

Detection and characterization of malonic acid. J. BOUGAULT. *Ann. chim. anal.* 23, 154-5(1918).—A résumé of a previous paper (*C. A.* 8, 478). B. reports the soly. in  $H_2O$  of the cinnamylidene compd. as 0.02%, and suggests this correction in quant. detns. The disadvantage in the use of Ca malonate for the prepn. of the compd. is obviated by the addition of 0.5 g.  $AcONa$ .  
F. W. SMITHER.

The oxidizing action of potassium dichromate as compared with that of pure iodine. CARL R. McCROSKY. *J. Am. Chem. Soc.* 40, 1662-72(1918).—Analytical reactions of  $K_2Cr_2O_7$  were studied to det. its status as an analytical standard. Some samples liberate more I in the oxidation of HI than is indicated by the normal equiv. The removal of dissolved air by means of indifferent gases acts as a corrective of this. Varying results are due to such impurities in the  $K_2Cr_2O_7$ , as are not removed by crystn., crystn. alone not being sufficient to produce theoretical values. I. F. S.

Important change in a sodium thiosulfate solution. H. I. WATERMAN. Dordrecht. *Chem. Weekblad* 15, 1098-9(1918).—Although standard  $Na_2S_2O_3$  solns. usually keep for months, one was observed to change in 1 month from 0.923 to 0.981 N, and in 15 days more to 1.023 N (measured iodometrically), after which it remained const. The change is too great to have been caused by the presence of  $CO_2$ . The cause is not known, but the change indicates that old  $Na_2S_2O_3$  solns. are not to be relied upon.

JULIAN F. SMITH.

A new indicator of vegetable nature. C. MARINI. Torino. *Ann. chim. applicata* 19, 32-6(1918).—M. made a study of the coloring matter of the myrtleberry. The method of prepn. is as follows: Take 250 g. dry, very ripe berries of the myrtle well cleaned of stems and leaves, mix with 750 g. 90% alc., and heat under a reflux for 1 hr. Decant and filter. Add to the wine-red colored filtrate 1 cc. N alc. for every 200 cc.

liquid, and divide into 2 equal parts. Make 1 of these parts still more alkaline so that 10 drops of the tincture placed in a tube with 10 cc.  $H_2O$  give a green color with 1 or 2 drops of  $N$  alk. and then change to a carmine with 1 or 2 drops of  $N$  acid; the edges of the liquid will have a greenish color. Take the other half, make it alkaline with the same vol. of alkali as used with the 1st half, then acidify with 1 cc.  $N$  acid, producing a liquid having wine-red edges. Mix the 2 halves together. Divide again into 2 equal parts, add  $\frac{1}{2}$  cc.  $N$  acid to one part, and mix the parts together again. Divide into halves once more, make the 1st alkaline with the least possible amount of alkali that colors the edges green; acidify the 2nd with 0.1  $N$  acid till the edges are colored wine-red. Keep the 2 liquids sep. Immerse slips of paper in each. When dried, those from the alkaline liquid will be colored a beautiful green, while the acid liquid will produce slips of a Bordeaux-red color. Two drops of weak acid (0.005  $N$ ) will produce upon the green paper a carmine-red. Two drops of weak alkali (0.005  $N$ ) will change the Bordeaux-red paper to a dark green. The indicator is more sensitive than turnsole.

ROBERT S. POSMONTIER.

**Determination of albuminoid ammonia in liquids containing gas liquor.** H. F. STEPHENSON. *Analyst* 43, 213-4(1918).—Allowance must be made for the thiocyanate present. To a measured portion of the liquid (which should be alk.) add  $Al_2(SO_4)_3$  sufficient to give a decided ppt. Shake well, allow to stand for a few mins. and then filter under suction through ignited asbestos. Acidify the clear filtrate with dil.  $HNO_3$  and remove thiocyanate by means of  $AgNO_3$ . Transfer the final filtrate along with the asbestos filter and adhering ppt. to the distn. app., make alk. with  $Na_2CO_3$  and est. albuminoid  $NH_3$  in the usual way. Owing to  $AgCNS$  being slightly sol., the figures obtained as above are always too high by a small amt., which is practically const. A blank expt. with distd.  $H_2O$  to which a little thiocyanate has been added will det. the necessary correction once for all.

H. M. LANCASTER.

**New reaction of formic acid and bisulfites.** E. COMANDUCCI. Univ. Naples. *Boll. chim. farm.* 57, 101-2(1918).—C. has previously shown (*Rend. soc. chim.* 1904, No. 16) that  $HCO_2H$ , when gently heated with a concd.  $NaHSO_3$  soln., produces a characteristic yellowish red color which is not given by substances such as glycerol,  $AcOH$ ,  $MeOH$ , etc., in which  $HCO_2H$  occurs as an impurity; this test cannot be directly applied to a liquid which is red or yellow in color but may be made upon a distillate obtained by distg. the liquid in a current of  $CO_2$ . C. now finds that the test can be directly applied to such a colored liquid provided it is gradually heated with  $NaHSO_3$  to incipient boiling and is then cooled and treated with a dil., freshly prepd. soln. of Na nitroprusside;  $HCN$  is evolved and a more or less intense green or blue coloration, depending on the amt. of  $HCO_2H$  present, is produced. The test is rendered more sensitive by pouring the Na nitroprusside soln. on the 1st mixt. so as to form 2 layers; a green zone which soon turns blue and finally yields a blue ppt. is produced. Formates also give this color reaction. The latter is due to the reaction of Na nitroprusside with the  $Na_2S_2O_4$  produced by the reaction of  $NaHSO_3$  and  $HCO_2H$  or  $HCO_2Na$ . A concd., freshly prepd.  $Na_2S_2O_4$  soln., when mixed with a dil., freshly prepd. Na nitroprusside soln., causes evolution of  $HCN$  and  $SO_2$  and the production of a green or blue color with finally a blue ppt.; when  $Na_2S_2O_4$  is present in excess the liquid is colored dark red and then becomes blue with evolution of  $HCN$ . The above reaction is not produced when  $K_4Fe(CN)_6$  or  $K_3Fe(CN)_6$  is substituted for Na nitroprusside. The above blue ppt. had a compn. corresponding to  $Fe_2(CN)_4Na_4$ .

H. S. PAINE.

**Use of enzyme reagents. II. Detection of pyrimidone and differentiation of the naphthols.** LUCIANO P. J. PALET. *Anales. soc. quim. Argentina* 6, 250-7(1918); cf. *C. A.* 12, 1333.—A poorly defined violet-blue color was obtained after about 24 hrs. when a well washed root (containing oxidases and peroxidases) of *Medicago sativa*

was added to a soln. of pyramidone. The appearance of the color was hastened by also adding a few drops of  $H_2O_2$  but the intensity of color was not increased; when, in addition,  $\alpha$ -naphthol was added a distinct wine-red color was almost instantly produced. When  $\beta$ -naphthol instead of  $\alpha$ -naphthol was added there was produced a blue color which changed at once to yellow with greenish tints;  $\alpha$ - and  $\beta$ -naphthols may thus be differentiated and traces of  $\alpha$ -naphthol may be detected in the presence of a great excess of  $\beta$ -naphthol. Since pyramidone is usually present in excess in such cases a blue color first appears, but the pieces of alfalfa root gradually turn red if  $\alpha$ -naphthol is present. The color changes observed after 24 hrs. contact of (1)  $\alpha$ -naphthol + alfalfa root, (2) the preceding +  $H_2O_2$ , and (3) the immediately preceding + pyramidone were: (1) roots slightly blue, liquid colorless; (2) roots intense blue, liquid blue; (3) roots and liquid, intense red. The corresponding color changes when  $\beta$ -naphthol was substituted for  $\alpha$ -naphthol were: (1) no change; (2) roots slightly yellow, liquid colorless; (3) roots and liquid, orange. In toxicological examn. by the Stass-Otto method the ordinary tests for pyramidone are either not sp. or are masked, since most of the alkaloids and medicaments such as antipyrine and antifebrine are found in the same analytical group ( $Et_2O$  ext. of a soln. rendered alk. with  $NaOH$ ). The following procedure gave satisfactory results in the case of partially decompd. viscera containing an abundance of ptomaines and a minute amt. of pyramidone. A portion of the residue from evapn. of the alk.  $Et_2O$  ext. was dissolved in a small amt. of distd.  $H_2O$  and transferred directly to a test tube without filtering and without removal of fatty and resinous substances. A well washed portion of alfalfa root and 4-5 small crystals of  $\alpha$ -naphthol were added and the mixt. was shaken and allowed to stand; the root acquired a more or less intense red color. This color may be estd. by washing the root with distd.  $H_2O$  and shaking in alc.

H. S. PAINÉ.

## 8. MINERALOGICAL AND GEOLOGICAL CHEMISTRY.

EDGAR T. WHERRY AND J. H. BOWER.

The dispersion of the optic axial angle of monoclinic feldspars. S. KÔZU. *Bull. soc. franc. min.* 40, 36(1917); *J. Geol. Soc. Tokyo* 25, 31-7(1918).—An equation is presented for determining the dispersion formula of the optic axial angle in monoclinic feldspars when  $V$  is large. The  $n_s$  computed from this formula are compared with the observed values, determined by the total-reflectometer.

S. G. GORDON.

Tear-figures on certain minerals. I, II. MIKIO KUHARA. *Mem. Coll. Eng. Kyoto Imp. Univ.* 1, 267-74, 279-86(1917).—Characteristics of the tear-figures on stibnite, galena, sphalerite, pyrite, vivianite, enargite, calcite, gypsum and barite are described.

J. H. B.

Radiation pattern of the transformation of magnesium hydroxide to magnesium oxide; serpentine, malachite, and pseudomorphous quartz; Bultfontein apophyllite; diamond tests by radiation patterns; diffraction from the edges of a square plate of iodine. J. S. V. D. LINGEN. *Trans. Royal Soc. S. Africa* 7, 59-63(1918).—A perfect piece of brucite showing the usual interference pattern without radial lines on transmitting Röntgen rays parallel to the trigonal axis, was heated over  $300^\circ$ . The mineral then showed only 6 radial lines, which increased in number, when exposed at room temperature, with no trace of the usual pattern. The displacement of the water mols. thus causes a displacement of the 3 principal points of the usual pattern, so that they become drawn out along radial lines, which seems to indicate a weakening of the lattice of the original homogeneous crystal, with a uniform displacement of the reflecting planes. A plate of Carolina (Transvaal) serpentine was placed so that the threads

were perpendicular to the incident rays, and exposed for 4 hours. The plate showed a pattern symmetrical about the direction of the threads, the radial lines parallel to the threads showing a greater intensity than the subordinate lines. This symmetry indicates that serpentine is not triclinic. Malachite cut parallel to the slightly radiating fibers showed three lines parallel to the threads, and a number of secondary lines perpendicular to the principal line. Quartz pseudomorphous after crocidolite showed an intense dispersion around the central spot, accompanied by thin radial lines, making a small angle in the direction of the threads, indicating that the substance is microcrystalline, and that the miniature crystals are so oriented that their normals to the reflecting planes favor the direction of the threads. The radial lines indicate the loci of the principal point pattern of the original crystal, and also give an indication of the stability of the lattice. A perfect and an imperfect apophyllite were successively irradiated normal to the cleavage plane. The imperfect crystal showed a discontinuity along the cleavage plane, indicating an irregular distribution of the intensity of the individual spot due to the irregularity caused by the cleavage cracks. A diamond twin showed the usual pattern, together with a similar one rotated through  $180^\circ$ . No discontinuity of the lattice was shown. A diamond with a black spot showed a slight discontinuity of some of the spots, but the lattice remained perfect. A spotted stone showed a ruptured lattice, the usual elliptic spots being represented by irregular discontinuous markings, spaced at various intervals. The diamond as a whole seems to consist of units more or less similarly oriented, each of which tends to produce its individual pattern. A 4 mm. square plate of I exposed for an hour normal to the diaphragm showed diffraction from the edges of the crystal. S. G. GORDON.

**Kimberley diamonds, especially cleavage diamonds.** J. R. SUTTON. *Trans. Royal Soc. S. Africa* 7, 65-96(1918).—A detailed description of the physical properties of the diamonds from the several S. African localities. The stones in any one pipe are remarkably uniform, but from one to another pipe they differ markedly in quality, size, crystallization, surface, color, general appearance, texture and tone. In addition to the gem diamonds, bort and "stewartite" also occur, the latter being a bort high in Fe, which is steel-gray, fibrous, equal in hardness to diamond, but lower in sp. gr., about 3.45, and also showing magnetic polarity. The explosive fracturing of diamonds is believed to be connected with the presence of inclusions having greater coefficients of expansion. Trade terms are discussed, and it is pointed out that "cleavages" includes not only broken fragments, but also mis-shapen stones that require cleaving before cutting. Statistics of production are included. S. G. GORDON.

**Pyrolusite from Virginia.** THOMAS L. WATSON AND EDGAR T. WHERRY. *J. Wash. Acad. Sci.* 8, 550-60(1918).—The geology of the Mn deposits near Woodstock, Va., is described in detail. A cryst. mineral having the physical properties of pyrolusite is abundant there. Two new analyses, by S. D. Gooch, are presented and compared with those of "pseudomanganite" from India. The  $MnO_2$  in all of them is over 92%, confirming the detn. as pyrolusite. An elaborate crystallographic study of the Va. mineral has been made, and the axial ratio proves to be close to that of some manganite, although there are 7 forms not heretofore noted on that mineral, and the habit is likewise unusual, being hemimorphic on the  $b$ -axis. The difference between the axial ratio and that usually accepted for manganite is perhaps connected with the loss of H, corresponding to the change into pyrolusite, taking place chiefly in the direction of the  $b$ -axis. On the other hand, the material may not be pseudomorphous at all, but represent primary pyrolusite, and further studies are to be undertaken to throw light on this question. E. T. W.

**Geology and ore-deposits of the Platoro-Summitville mining district, Colorado.** HORACE B. PATTON. *Colo. Geol. Survey, Bull.* 13, 122 pp.(1917).—The rocks of

this district are described petrographically, analyses of quartz-biotite latite, biotite-hornblende latite-vitrophyre, augite-andesite, and monzonite being given. The rocks show extensive alteration, to kaolinite, sericite, alunite, etc. There is considerable pyrite scattered through some of the altered rocks, and on weathering it gives rise to Fe sulfates, which yield a bitter taste to the surface waters; 4 analyses of these are given. From a complete analysis of an alunite-bearing rock, its mineral compn. is calcd. to be: alunite, 31.22; kaolinite, 43.33; quartz, etc., 25.57; sum 100.12%. The physiography and geology, and the individual mines are described in detail. At one locality covellite occurs in large amount, sometimes in good crystals over 2 inches across. The ore deposits appear to be due mostly to ascending waters, but the association of Au with limonite shows clearly that secondary concn. by meteoric waters has occurred.

E. T. W.

**Manganese ore in Georgia.** ANON. *Science* 48, 360-2(1918).—Examn. shows the existence of large reserves of both high-grade Mn ore and Mn-Fe ore. The high-grade ore of Cartersville contains about: Mn 42.0, Fe 6.0, SiO<sub>2</sub> 6.0, P o. 14 to o. 20%. The Mn-Fe ore of the district: Mn 15.0, Fe 20.0, insol. 30.0, P o. 17%. J. H. B.

**Two-phase convection in igneous rocks.** FRANK F. GROUT. *J. Geology* 26, 481-500(1918).—Based upon a study of the Duluth gabbro, the idea of a convection circulation in magmas is considered possible. This paper summarizes the signs of convection and suggests its probable mechanism and results. The forces necessary to start a current seem to be ample and are furnished in part by cooling and by the increase in d. of growing crystals which is probably more important than the development of any gas or separate liquid phases. The idea of convection is of practical service when related to the banded structure. By it the position of the walls of the chamber may be found. The complexity of some differentiated rock series may also be explained by assuming that some of the series developed during convection. W. F. HUNT.

**Notes on a collection of rocks from Honduras, Central America.** WILBUR G. FOYE. *J. Geology* 26, 524-32(1918).—A petrographic description of the igneous and metamorphic rocks from the province of Atlantida, northwestern Honduras, and from the Island of Utila. No chem. analyses are given. W. F. HUNT.

**The granite and its satellites in Mount Hiei environs.** TADASU HIKI. *Mem. Coll. Eng. Kyoto Imp. Univ.* 1, 275-8(1917).—It is concluded that the various rocks, erupted successively, resulted from differentiations of the same kind in different degrees, in a granitic magma chamber. It is also clear that the rocks of this group differ in only megascopic character and geological relation, but not in compn. nor in general community of character. Analyses and photomicrographs are given. J. H. B.

**Volume changes in metamorphism.** WALDEMAR LINDGREN. *J. Geology* 26, 542-55(1918).—Metamorphism is defined as the sum total of the chem. and mechanical changes which take place in solid rocks, below the zone of oxidation. The agents are heat, pressure, and chem. energy. It is believed that metamorphism by replacement does not normally involve changes in vol., as replacement proceeds particle by particle, though not mol. for mol. Replacement takes place, however, independently of sp. gr. and mol. vol. Replacement is dependent upon the velocity of the soln. movement, and upon compn., pressure and temp. of the replacing soln. A good proof that no vol. change takes place during metamorphism is furnished by the frequent preservation of the preëxisting texture and structure. In the case of the serpentinization of Mg rocks which is often cited as a case of expansion by replacement, it seems more probable that replacement has been effected with the removal of some magnesia; this contention is supported by the existence of ascending Mg waters where serpentine is abundant, as in Cal.

W. F. HUNT.

**The nature and origin of the stylolitic structure in Tennessee marble.** C. H. GORDON. *J. Geology* 26, 561-9(1918).—Stylolites are irregular, dark-colored, interlocking seams which resemble the sutures of the human skull. These structures consist of striated, tooth-like projections or columns which project from opposing surfaces along a plane of fracture. Apparently the most satisfactory explanation is that known as the soln. theory, unequal soln. along planes of fracture after the consolidation of the rock. Due to the weight of the overlying mass, soln. will take place more rapidly on the concave surfaces opposite the columns, causing these to penetrate into the opposing surfaces. W. F. HUNT.

**The depth of dolomitization.** FRANCIS M. VAN TUYL. *Science* 48, 350-2(1918).—Van T.'s experience with regional dolomites of undoubted secondary origin contains considerable evidence in support of the contention that many of the dolomites represent shallow water deposits. J. H. B.

**Metalliferous laterite in New Caledonia.** W. M. DAVIS. *Proc. National Acad. Sci.* 4, 275-80(1918).—Comprizes chiefly physiographic contributions to the historical geology of the island. J. H. B.

## 9. METALLURGY AND METALLOGRAPHY.

WILLIAM BRADY, WILLIAM T. HALL.

**Recording experimental flotation tests.** A. F. TAGGART. *Eng. Mining J.* 106, 751-2(1918).—The author gives a form "devised to guide investigators in the Hammond lab. in the performance and recording of flotation test work."

F. W. SMITHER.

**Effect of oxygen on the precipitation of metals from cyanide solutions.** O. P. WATTS. *Chem. Met. Eng.* 19, 652-3(1918).—Discussion of a paper by Crowe (*C. A.* 12, 2183). In opposition to C.'s view that pptn. of Au is brought about by H which has been displaced by Zn, and that the removal of dissolved air is beneficial because it prevents oxidation and loss of this reducing agent, W. considers that the Au is directly displaced from soln. by Zn, just as the same metal displaces Cu from a soln. of  $\text{CuSO}_4$ . "Besides causing a loss of Zn, dissolved air lessens the efficiency of recovery by accelerating re-soln. of the Au already pptd., just as air aids the dissolving of metals in cyaniding ores. It is this 2-fold action that makes dissolved air a factor to be reckoned with in the economics of Au recovery."

F. W. SMITHER.

**Smelting and lead refining at the Bunker Hill plant.** C. T. RICE. *Eng. Mining J.* 106, 743-9(1918).—A detailed description, with numerous illustrations, of the design and operation of the blast furnaces, types of blowers used, the arrangements for Pb tapping, modes of conveyance of the various products about the plant, including the pumping, by centrifugals, of molten Pb. The details of the Parkes process, and the use of Faber du Faur furnaces in refining the products, are also described. The blast furnace charge carries 35 to 40% Pb and only 1 to 3% Zn. The slag analyzes FeO, 32; ZnO, 2 to 4;  $\text{SiO}_2$ , 32 to 33; CaO, 16; MnO, 3; Pb, 1%. F. W. SMITHER.

**Lead refining at the Bunker Hill plant.** C. T. RICE. *Eng. Mining J.* 106, 771-7(1918).—A detailed description, with illustrations, of the refinery practice. Pb, Ag and Au are produced. Special app. (e. g., the Miller casting machine), baghouse construction and operation, and the Cottrell system are described. The refined Pb assays 99.989% Pb, 0.002% Sb, 0.0005% Cu, a trace of Zn, 0.15 oz. Ag per ton, As and Bi nil. F. W. SMITHER.

**Copper leaching by salt-water and sulfurous gases.** C. S. VADER. *Mining Sci. Press* 117, 457-8(1918).—A  $\text{NaCl}$  soln. impregnated with  $\text{SO}_2$  becomes a powerful sol-

vent for Cu. In the past, the failure of large-scale attempts to utilize this process was due to the attempt to sat. water by merely blowing  $\text{SO}_2$  through it, to poor agitation, to the dil.  $\text{SO}_2$  soln. obtained, 1% being the max. amt. of Cu which can be held in soln. by  $\text{SO}_2$ , to the ease with which the Cu seps. from the soln. in the leaching-, press- and filter-tanks, forming throughout the mass of leached ore cuproso-cupric ppt., which is practically insol. in  $\text{H}_2\text{SO}_4$ , and to the difficulty of treating the remaining 40% of the Cu in soln. as  $\text{CuSO}_4$ , after 60% has been removed by pptn. on scrap Fe. The use of NaCl with  $\text{H}_2\text{SO}_4$  prevents the formation of cuproso-cupric sulfite. Tests made on an ore containing 1.3% Cu, and 0.016 oz. Au and 0.21 oz. Ag per ton gave, on grinding the ore to 4 mesh and treating 6 hrs. with a NaCl- $\text{SO}_2$  soln., an extn. of 66% of the Cu, 6.25% of the Au and 52.38% Ag. On grinding to 20 mesh the extn. was 88.35% Cu, 37.50% Au and 60% Ag. By grinding to 100 mesh 91.96% of the Cu, 62.5% of the Au and 61.9% of the Ag was extd. Any Fe which goes into soln. with the Cu from the ore can be recovered as follows: The  $\text{FeSO}_4$  formed is oxidized to  $\text{Fe}_2(\text{SO}_4)_3$  by applying gentle heat and blowing air through the soln. As fast as the  $\text{Fe}_2(\text{SO}_4)_3$  forms it is decomposed with formation of  $\text{Fe}_2\text{O}_3$  and  $\text{SO}_2$  which can be recovered from the soln. at almost any desired stage of the process. The Fe thus pptd. and recovered is to be used for making sponge-Fe to ppt. the Cu from the NaCl- $\text{SO}_2$  soln. E. A. TSCHUDY.

The new Merton furnace for roasting blende. ANON. *Eng. Mining J.* 106, 569-70(1918).—The furnace is of the muffled or semi-muffled type and the ore is fed in two places to two separate sets of rabbles. In its progress through the several hearths of the furnace it is confined to the set of rabbles to which it was originally fed. It is finally discharged through chutes. This arrangement results in a more uniform and complete roasting of the ore and a min. production of hearth accretions. The fuel consumption is decreased by the use of waste heat and the furnace may be readily adapted to different grades of ore by reason of the control of the air supply and hearth temp. The ore does not travel the whole length of the hearths but remains within the rabble zone of the two adjacent shafts. The hearth area of the Merton furnace is four times that of a circular furnace of similar design. The ore passes from hearth to hearth at points far removed from the gas outlets so that dusting loss is reduced to a min. The air required for the combustion of the S in the muffle hearths is preheated in the regenerator and delivered under slight pressure by means of a fan. The heated air resulting from the cooling of the roasted ore on the bottom hearth is utilized in the grate combustion chamber. E. A. TSCHUDY.

Standards for protective finishes for iron. E. P. LATER. *Foundry* 46, 424-6 (1918).—Electrochem. finishes such as Zn galvanizing, and purely physical finishes as metallic Cu, lacquers, and paints, are differentiated and their uses discussed. There is great lack of uniformity in specifications for protective plating. Proposed types of standards include weight of deposit per unit area or resistance to a standard accelerated corrosion test. Since most metallic plate is more or less porous, the latter would give a better service indication, especially on thin plate. Plate on Fe may be tested for porosity by the  $\text{H}_2\text{SO}_4$ - $\text{K}_3\text{Fe}(\text{CN})_6$ -agar reagent, which gives a blue color where the Fe is exposed. For Zn coatings, however, the method cannot be used; such plate if immersed in hot concd. NaOH gives a stream of bubbles where the Fe is exposed, Cu films up to about 0.00034 in. and Ni up to 0.00102 in. contain pinholes. Brass coatings of 0.00128 in. were free from them. Double coatings of Zn and then Cu were no more resistant than a Cu or brass coating of the same thickness. S. L. CHISHOLM.

Deformation of steel castings. T. BROWN. *Foundry* 46, 411-3(1918).—The deformation of steel castings may be caused by contraction during the cooling of the metal from the molten condition or by expansion during annealing operations. Methods of overcoming such defects are discussed. E. E. RICHARDSON.

Calculation of extraction in continuous agitation (HAM, COE) 18. Evaluation of zinc dust (WILSON) 7. Potash as a by-product (GRASTY) 18. Recovery of potash from iron blast furnaces (BRADLEY) 18. Washing coal, ores, etc. (Brit. pat. 119,038) 18.

**Concentrating ores.** W. A. SCOTT. Brit. 118,627, Aug. 14, 1918. A method of carrying out a froth-flotation process consists in introducing into the ore pulp a mixt. of a vaporized mineral-frothing agent and air, and thereby forming a froth of the concentrates at the surface of the liquid. A suitable app. is specified. Cf. 20,419, 1903, 7,803, 1905, 2,359, 1909, and 21,857, 1910 (C. A. 6, 1426).

**Treatment of copper ores.** W. H. HYATT and E. N. FELLOWES. Brit. 116,181, July 6, 1917. Cu is extd. from Cu ores by treatment with a soln. of niter cake in an excess of  $H_2O$ , metallic Cu being obtained from the soln. thus formed by any usual method, or this soln. may be neutralized with a suitable carbonate to produce an insecticide. According to the provisional specification, metallic Cu may be treated with niter cake soln. and then a suitable carbonate added in order to prep. an insecticide. Cf. 21,424, 1901.

**Concentrating ore by flotation.** T. A. JANNEY and C. M. NOKES. U. S. 1,281,018, Oct. 8. In concg. ores such as slimes of Utah Cu ore, the ground ore is mixed with  $H_2O$ , a soln. of gilsonite in kerosene or fuel oil is added, followed by the addition of pine oil or other oil having greater frothing properties than the first-mentioned oil, and the mixt. is aerated.

**Metallurgical furnaces.** J. GAUNT, D. BROOKFIELD and TYLOR & SONS. Brit. 118,750, Nov. 24, 1917. A preheating charger for crucible and like smelting furnaces comprizes a casing with a refractory lining or hopper the base of which is formed with a curved deflecting surface terminating in a depending lip, with or without slotted passages therein, whereby the products of combustion from the interior of the furnace are led or conducted through the charge in the hopper.

**Recovering zinc from siliceous calcine.** F. LAIST. U. S. 1,281,031, Oct. 8. Siliceous Zn-bearing calcine is leached with an acid soln., the soln. is neutralized to ppt. silica in the presence of the insol. residue, the Zn-bearing soln. is then sepd. from insol. substances, the residue is dehydrated at a temp. of  $150^\circ$  and leached with 8%  $H_2SO_4$  soln., and the soln. thus obtained containing additional Zn is used for the first leaching step, in treating additional portions of the calcine.

**Recovering zinc from siliceous calcine.** F. LAIST. U. S. 1,281,032, Oct. 8. The calcine is leached with acid soln. and the soln. neutralized and sepd. as in the preceding pat., after which the residue is repulped with  $H_2O$ , forming a second dil. Zn-bearing soln. Zn is separately recovered electrolytically, from the 2 solns., using insol. anodes.

**Refining metals and alloys.** STABILIMENTI BIAK-ING. A. POUCHAIN. Brit. 116,277, May 7, 1918. A process for eliminating O and oxides from molten metal, particularly bronze and brass, consists in placing in the mold into which the metal is to be poured a substance which will absorb or combine with the O present. The substance may be a quantity of one or more of the metals of the alloy in powdered form enclosed in an envelope of an easily fusible metal such as Pb.

**Precipitating metal values from cyanide solutions.** T. B. CROWE. U. S. 1,281,249, Oct. 8. Cyanide solns. containing gases such as air which might interfere with the pptn. of metal values are treated with  $Na_2S$  or subjected to a vacuum to remove the entrained gases and the soln. is then brought into contact with a pptg. agent, e. g., metallic Zn. Cu solns. may be subjected to a vacuum before pptn. with Fe.

**Coating articles with metals.** F. A. VAUGHN. U. S. 1,281,108, Oct. 8. Articles to be coated with metals are given a priming coating of Na silicate to close the pores of the article and cover corrosion, rust or foreign matter on the surface, molten coating metal is then sprayed on to the surface and, if the metal coating thus applied is sufficiently porous, the article is then treated with  $\text{CO}_2$  to produce insol. compds. from the Na silicate.

**Reinforced lead sheet.** C. M. WALES and C. BASKERVILLE. U. S. 1,280,908, Oct. 8. Sheets of Pb reinforced with Fe or steel wire or wire gauze are formed by first dipping the reinforcing wires into an alloy such as Sb 10-13 and Pb 90-87% and then embedding the coated wires in Pb or a Pb alloy which forms the principal part of the sheet. The reinforced sheets thus formed are suitable for making gaskets or tank linings.

**Alloys.** F. MILLIKEN. Brit. 118,825, May 17, 1918. See U. S. 1,277,989 (C. A. 12, 2312).

**Aluminium alloy.** L. S. GARDNER. U. S. 1,280,706, Oct. 8. An alloy which has good tensile strength, can readily be bent without breaking and which may be easily machined to a smooth surface, which retains its original brightness indefinitely, is formed of Al 78, Cu 4, Sn 10, Zn 8, Mn 0.05 and Fe 0.07 parts.

**Aluminium alloys.** GEN. ELEC. CO. Brit. 118,947, Nov. 20, 1917. Al alloys contain about 6-12% Zn, about 0.5-2.5% Mg, and about 1-3% Fe, Cr, Co, Ni, Ti, or Mn, or a mixt. of these metals, the balance being Al. The Al is preferably melted first, then the Fe, etc., added, then the Zn, and finally the Mg, and the first stages of the working of the alloy are carried out at about 450°.

**Permanent magnets; alloys.** SUMITOMO CHUKOSKO, LTD. Brit. 118,601, June 26, 1918. Steel alloys for the manuf. of permanent magnets contain about 20-60% of Co (preferably about 35%). Other metals such as 0.5-20% of W, 0.2-15% of Mo, 0.3-10% of Cr, or V or like metal may be added. The % of C may be 0.3-2%. The forged article is hardened at about 900-1000° and is then magnetized.

**Permanent magnets; alloys.** SUMITOMO CHUKOSHO, LTD. Brit. 118,602, July 2, 1918. A steel alloy for the manuf. of permanent magnets contains about 20-60% of Co (preferably about 35%), 0.3-10% of Cr, and the remainder steel contg. about 0.3-2% of C. The forged article is hardened at about 900-1000° and is then magnetized.

**Metal castings.** L. LORENTOWICZ. Brit. 116,203, Sept. 26, 1917. Undesirable holes in castings are closed by cleaning, filling with powdered metal, and then heating to melt the powder. The opening is cleaned with a reamer driven by a flexible shaft, then by acid and a flux such as Zn, HCl, and  $\text{NH}_4\text{Cl}$ . The powdered metal such as Sn, Ag, Ni, Cu, or Sn alloyed with 2% of either or all of the other 3 metals, is inserted. The powder is then melted by an arc or concd. flame and pressed and rubbed by means of heavy "irons" made of Cu or Ni, preferably heated, and finally the surplus is scraped off and the surface finished correctly.

**Solder.** A. P. BEVAN. U. S. 1,281,126, Oct. 8. A solder suitable for use on uncleaned or imperfect surfaces is produced by heating to redness a mixt. of ordinary solder and a Cu alloy (composed, e. g., of Cu and Zn and fusible at a temp. higher than the solder), stirring the mixt. and then cooling it quickly to crystallize the Cu alloy in a state of fine subdivision.

**Soldering flux.** A. H. VAN MARTER. U. S. 1,280,905, Oct. 8. A flux suitable for use in soldering Al is formed of stearic acid 16, borax 2, rosif 2 and pulverized cinnamon bark 5 parts. The flux is preferably used with a solder composed of Sn 16 and Zn 5 parts.

**Coating metals.** E. E. BURNETT. Brit. 118,182, Oct. 4, 1917. Metals, particularly Fe and steel, are provided with a coating of Cr by treatment in a hot soln. of Cr or a Cr compd. such as chromite in  $H_2PO_4$ , the proportions being preferably such as to give an excess of acid in the soln.

---

## 10. ORGANIC CHEMISTRY.

---

CHAS. A. ROULLER.

Constituents of resins (ZINKE, LIEB) 26. Transformation of tetrahydronaphthalene in the animal body (SCHROETER, THOMAS) 11H. Pregl's microanalytical estimation of methyl groups attached to nitrogen (EDLBACHER) 11B. Use of enzyme reagents. II. Detection of pyrimidone and differentiation of the naphthols (PALET) 7.

---

**Oxalates from formates.** L. W. ANDREWS. U. S. 1,280,622, Oct. 8. In the manuf. of oxalates by heating the corresponding formates, *e. g.*, in making Na oxalate from Na formate, a small amt. of  $Na_3PO_4$  or other polybasic phosphate of an alkali metal is used as a catalyst. Complete reaction takes place at a temp. of about  $380^\circ$ .

**Oxalates from formates.** L. W. ANDREWS. U. S. 1,281,117, Oct. 8. In making oxalates from formates, *e. g.*, in making Na oxalate from the formate, the latter is heated with  $Na_3AsO_4$  or  $Na_3AsO_3$  or other alkali metal salt of an oxy acid of As which serves as a catalyst. U. S. 1,281,118 relates to the same method, except that the catalyst used is  $Na_3AlO_3$ ,  $K_3AlO_3$  or other Al compd. A temp. of about  $380^\circ$  is employed.

**Acetic acid.** S. UTHEIM. Brit. 116,279, May 13, 1918. In the manuf. of HOAc by treating AcH with O under pressure, the AcH is supplied to a confined reaction space sep. from the O and in limited quantities as required, in order to avoid explosions. Details of construction and operation of a suitable app. are specified. Cf. C. A. 12, 2573.

**Benzoic acid.** WESTON CHEMICAL CO. and J. SAVAGE. Brit. 116,348, June 7, 1917. Benzoic acid is prepd. by chlorinating boiling toluene so as to produce benzyl chloride, benzal chloride, or mixts. thereof, then heating these first with a soln. of an alkali or alk. earth, and then oxidizing by means of a hypochlorite; the resulting soln. of a benzoate is treated with an acid to ppt. benzoic acid.

**Sulfonic acid.** H. BULL. Brit. 118,727, Oct. 23, 1917. Aromatic hydrocarbons are sulfonated by continuously passing an excess of the hydrocarbon through  $H_2SO_4$ , the resulting soln. of the sulfonic acid in the excess of hydrocarbon being continuously removed. Preferably, the hydrocarbon and the  $H_2SO_4$  are continuously brought into contact on the counter-current principle. A suitable construction is specified.

---

## 11. BIOLOGICAL CHEMISTRY.

---

HATTIE L. HEFT AND WILLIAM J. GIES.

### A. GENERAL.

FRANK P. UNDERHILL.

**Formation of esters of phosphoric acid during alcoholic fermentation.** A. LEBEDEV. *Biochem. J.* 12, 87-92(1918).—A fermenting soln. of yeast, sucrose and phosphate, when treated with alc., gives a mixt. of esters of phosphoric acid. From the latter an osazone,  $C_{28}H_{57}O_7N_8P$  (m.  $142-144^\circ$ ), can be isolated. A *p*-bromophenylosazone (m.  $141-142^\circ$ ) and a Ba salt are also described.

B. HARROW.

**The action of ethyl alcohol and acetone upon lipase.** G. KITA AND M. OSUMI. *J. Tokyo Chem. Soc.* 39, 13-22(1918).—Activity tests of the lipase in absorbent castor beans were carried out with soy bean oil in dil. acetone and EtOH solns. at room temp. In acetone soln., the enzyme retained its activity but not in EtOH soln. S. K.

**The influence of lipoids on the rate of reaction.** M. SIEGFRIED. *Biochem. Z.* 86, 98-109(1918); *J. Chem. Soc.*, 114, II, 223.—Lecithin inhibits the transformation of yellow  $\text{HgI}_2$  into the red variety, and also the reduction of  $\text{NH}_4\text{OH} \cdot \text{AgNO}_3$  by  $\text{PhNHNH}_2$ . The latter reaction should be carried out in the dark; in the presence of even diffuse sunlight the inhibiting action of the lipid is diminished. C. J. WEST.

## B. METHODS AND APPARATUS.

STANLEY R. BENEDICT.

**Determination of ammonia in urine, serum, etc.** H. WIESSMANN. *Landw. Vers. Sta.* 91, 347-52(1918); *J. Soc. Chem. Ind.* 37, 532A.—Ten cc. of sample plus 40 cc.  $\text{H}_2\text{O}$  plus 10 cc. of 10%  $\text{Na}_2\text{CO}_3$  soln. are distd. at  $50^\circ$  and 5 to 10 mm. are collected in standard  $\text{H}_2\text{SO}_4$ . The distn. takes about 45 min. Urea yields no  $\text{NH}_3$  under these conditions. L. J. GILLESPIE.

**Blood transfusion by the sodium citrate method.** S. W. SAPPINGTON. Hahnemann Medical Coll., Phila. *Hahnemannian Monthly* 53, 518-35(1918).—The conclusion is reached that the Na citrate method of blood transfusion is so simple and possesses so many advantages that it approaches the ideal method. J. S. H.

**Some simple valves for respiration apparatus.** A. D. HIRSCHFELDER AND E. D. BROWN. *Proc. Am. Physiol. Soc., Am. J. Physiol.* 45, 567(1918).—Directions are given for making simple valves for respiration app. G. McGUIRE.

**A simple stalagmometer.** A. D. HIRSCHFELDER. *Proc. Am. Physiol. Soc., Am. J. Physiol.* 45, 567(1918).—Directions are given for making a stalagmometer of any desired frequency. G. McGUIRE.

**New volumetric method for the estimation of phosphates in urines.** ARGO ANGOLANI. *Giorn. farm. chim.* 66, 251-2(1917); *J. Chem. Soc.* 114, II, 240.—Twenty-five cc. of the urine are treated with 1 cc. of 20%  $\text{HCl}$ , 1 g.  $\text{NH}_4\text{Cl}$  and 10 cc. of a citric acid and Mg soln. (a soln. of 35 g.  $\text{MgO}$  and 260 g. citric acid, the total vol. being 500 cc., which is then treated with 400 cc. of 10%  $\text{NH}_4\text{OH}$  soln. and kept for 2 hrs.). The ppt. is collected, washed with very dil.  $\text{NH}_4\text{OH}$  soln., dried at  $30-40^\circ$  and then dissolved in 50 cc. of 0.1  $N$   $\text{H}_2\text{SO}_4$  the excess of which is titrated with 0.1  $N$   $\text{NaOH}$ , using methyl orange as indicator. One cc. of 0.1  $N$  acid is equivalent to 3.55 mg.  $\text{P}_2\text{O}_5$ . H. S. PAINE.

**Microchemical method of estimating residual nitrogen.** IVAR BANG. *Biochem. Z.* 87, 259-63(1918); *J. Chem. Soc.* 114, II, 273.—The urea can be first extd. from the blood sample on filter paper by treatment with alc.- $\text{Et}_2\text{O}$  mixture for 5 hrs., and the remaining N is then extd. with phosphomolybdic acid soln. (0.05% phosphomolybdic acid + 1.5%  $\text{H}_2\text{SO}_4$ ) for 1 hr. The N in each ext. is estd. by the micro-Kjeldahl method. C. J. WEST.

**Preparation of a soluble concentrated product of the thyroid gland.** J. M. ROGOFF. Western Reserve Univ. *J. Pharmacol.* 12, 207-9(1918).—Kendall's product, obtained by alkaline hydrolysis of normal thyroid, was further hydrolyzed with dil.  $\text{HCl}$ ; the resulting soln. was filtered through a Chamberlain filter, the clear filtrate pptd. with hydrated  $\text{Al}$  silicate, and the ppt. filtered off and washed with water until free from acid. The adsorbed product was sepd. by slowly percolating through the material on the filter a dil. soln. of  $\text{NH}_4\text{OH}$  until the percolate was entirely colorless. The filtrate was heated and the  $\text{NH}_3$  removed by a current of air. The product obtained on evapn. contained

13.44 mg. of I per g. of dry substance. This had about the same activity as the original material. C. J. WEST.

**Acid production graphically registered as an indicator of the vital processes in the cultivation of bacteria.** ALBERT FISCHER. Copenhagen. *J. Exp. Med.* 28, 529-46 (1918).— $\text{CaCO}_3$  is added to the culture and the  $\text{CO}_2$  production followed by means of a small spirometer, the movements of which are recorded on a rotating cylinder. The curve obtained in this way corresponds exactly to the one found by titration. Effects of *B. coli* upon the *B. paratyphosus* curve are studied. C. J. WEST.

**The colorimetric estimation of hemoglobin as acid hematin.** LADISLAUS BERCZELLER. *Biochem. Z.* 87, 23-35 (1918); *J. Chem. Soc.* 114, II, 340.—By means of an Autenrieth colorimeter, hemoglobin can be estd. as acid hematin, when a washed suspension of corpuscles is employed. The method cannot, however, be employed for detg. the amt. of hemolysis in, for example, the Wassermann reaction, as it is interfered with both by the presence of serum and the soln. of the antigen in org. solvents. C. J. WEST.

**Experiments in differentiation of blood and muscular albumin precipitation and anaphylaxis.** C. LOPEX. *Am. J. Vet. Med.* 12, 853-7; *Exptl. Sta. Rec.* 38, 583.—To obtain pptg. serum for blood serum, the best method is that of intravenous injections of 20 cc. each of horse serum into rabbits weighing at least 3 kg. For the differentiation of albumin of the muscles, the best and most easily obtained and preserved antigen is that obtained by adding NaCl to minced meat and dialyzing the juice through parchment paper. When a greatly accentuated degree of specificity is required, as in dealing with meats denaturated by heat, L. has found anaphylaxis reactions superior to precipitins for the differentiation of albumins. C. J. WEST.

**Mycological detection of reducing substances in urine.** A. CASTELLANI AND F. E. TAYLOR. *Brit. Med. J.*, Dec., 1917, Rep. 6 pp.; *Physiol. Abstracts* 3, 263.—Not only may various sugars be used to identify bacteria but the reverse process may be carried out. Six organisms were used, all of which cause fermentation (appearance of gas) of glucose. Five of these act on levulose, four on maltose and so on. The tube is first inoculated with *Monilia bulcania*; if gas appears glucose is present; then with *M. krusei*, a positive result indicating levulose; then in turn with *M. pinoyi*, *M. metabudinensis*, *B. coli* and *B. paratyphosus*, positive results indicating in the order named maltose, galactose, pentose and lactose. If none of the organisms give rise to gas formation, the reducing substance must be creatine, uric acid, hippuric acid or other non-fermenting material. C. J. WEST.

**Detection of sugar in urine by means of an alkaline copper solution.** H. RUOSS. *Z. physiol. Chem.* 101, 193-209 (1918); *J. Chem. Soc.* 114, II, 337; cf. *C. A.* 12, 916.—A modification of the Worm-Müller test is described in which the quantity of the alk. Cu reagent to be boiled with 5 cc. of the urine depends on the density of the urine. The no. of cc. of reagent required is detd. by the formula  $83(D-1) + 0.7$ , where  $D$  is the density of the urine. If a deposit of red  $\text{Cu}_2\text{O}$  fails to form when the calcd. vol. of the reagent is mixed with 5 cc. of the urine under the prescribed conditions of temp. and diln., the urine is normal. By the addition of glycerol to the reagent, its delicacy is greatly increased, so that the presence of dextrose can be detected in even normal urines. C. J. WEST.

**Pregl's microanalytical estimation of methyl groups attached to nitrogen.** S. EDLBACHER. *Z. physiol. Chem.* 101, 278-87 (1918); *J. Chem. Soc.* 114, II, 336.—An account of the difficulties in carrying out Pregl's method, and of various improvements by means of which they have been overcome, the principal being the adoption of a quartz flask instead of a glass one, and the addition of a catalyst, gold chloride, which

so accelerates the cleavage of the alkyl groups that the whole operation can be completed in 1 distn. occupying about 30 min.

C. J. WEST.

Reactions of gold fish to certain habit-forming drugs (SHELFORD) 17.

### C. BACTERIOLOGY.

**Fermentation of glyoxylic acid.** A. LEBEDEV. *Biochem. J.* 12, 81-6(1918).—Dried yeast (Lebedev) decomposes glyoxylic acid with the production of CO<sub>2</sub> and acetaldehyde.

B. HARROW.

**Preservation of cholera stool specimens for delayed bacteriologic examination.** C. S. PANGANIBAN AND OTTO SCHÖBL. *Philippine J. Sci.* 13B, 275-80(1918).—The suspensions of cholera-infected stools in solns. of preservatives were kept at room temp. (32°) and examd. for cholera vibrios at intervals. Glycerol had no preserving action for the cholera vibrios, which survived for but 4 days in 20% and in 25% glycerol, and for but 2 days in 30% glycerol. The vibrios survived at least 5 weeks in solns. containing 0.25%, 0.5%, 1%, and 2.5% NaCl, resp., for 4 days in solns. containing 5% and 7.5% NaCl, resp., and for 3 days in solns. containing 10%, 12.5%, and 15% NaCl, resp. The vibrios survived at least 5 weeks when preserved in solns. containing 25%, 37.5%, and 50%, resp., of pure ox bile. Bile and NaCl soln. were found to give good results as preservatives of feces to be tested for the presence of the cholera vibrio. "Ox bile was found superior to NaCl soln. in those instances where the cholera vibrios were present in the feces in small numbers."

JOSEPH S. HEPBURN.

**The acid production of *Bacillus bulgaricus*.** W. M. CLARK. *Abstracts of Bacteriology* 1, 59-60(1918).—"Several cultures of *B. bulgaricus* were found to bring the hydrogen-ion concn. of various media to  $P_H$  3.8. This same value was found for the juice of silage and spontaneously fermented corn meal gruel, in both of which others have found *B. bulgaricus* to be dominant. A const. final hydrogen-ion concn. was not found so uniformly as in the studies on the colon and streptococcus groups of bacteria. This may be due to the difference in cultures or to the enormous difference in the rate of fermentation. "It was suggested that the complete suppression of other bacteria by the high acidities of the bulgaricus cultures is a phenomenon which has little to do with intestinal conditions, but that the lowering of the rate of growth of other bacteria or the rate of various bacterial processes by the ability of bulgaricus to maintain slightly higher levels of hydrogen-ion concn. may account for the effectiveness of certain strains of *B. bulgaricus*." Other bacteria might cause the same phenomenon with the utilization of the same carbohydrate diet. It is thought that the dynamic aspects of this problem, the suppression of putrefactive, pathogenic, or coliform organisms by the bulgaricus, should be studied.

GRACE MCGUIRE.

**The value of the petroleum-ether method for the isolation of *Bacillus typhosus* from feces.** LAWRENCE A. KOHN AND CHARLES KRUMWIEDE, JR. Dept. of Health, New York City. *J. Bact.* 3, 361-6(1918).—The method is considered unfavorable.

JOHN T. MYERS.

**Bacterial nutrition: further studies on the utilization of protein and non-protein nitrogen.** NATHAN BERMAN AND LEO F. RETTGER. Yale Univ. *J. Bact.* 3, 367-88 (1918).—The results obtained in the present investigation confirm those of previous expts. (C. A. 10, 3087), and further justify the assumption that bacteria require food substances which are of simple constitution and whose properties are such that they readily admit of absorption by the bacterial cell. No two brands of com. peptone are of the same compn., nor is it likely that any one product is uniform. Numerous tests have shown that the amino acid content of some products is decidedly greater than that of others, while the proportion of the albumose and complex polypeptide fraction is correspondingly less. The presence of a peptolytic enzyme in cultures of coli, typhi

and other gelatin-non-liquefying bacteria has apparently been demonstrated. This erepsin-like enzyme is, however, decidedly weak, and further differs from erepsin of the animal body in that it does not attack casein. The decompn. of biuret-giving material in com. peptone is, without doubt, limited to the substances of relatively simple constitution, or the lower polypeptides. Even the gelatin-liquefying and proteolytic bacteria are slow to make use of the proteoses and peptone in com. "peptone." Their initial development is at the expense of the simpler nitrogenous compds., and a reduction in the biuret-giving substances occurs only after a period of preliminary cultural development, this period often extending over at least a day or two. In this preparatory interval the proteolytic enzyme is formed which is necessary in the utilization of the sol. protein material. That the production of the enzyme which attacks gelatin is as a rule a slow process is well shown in the ordinary gelatin liquefaction tests. Bacteria are unable to decomp. coagulated native protein when there is no other source of available N in the test medium. There is reason to believe that purified proteose also is resistant to direct attack by bacteria. The ability of an organism to liquefy gelatin is no sure indication of its proteolytic properties. Gelatin and casein resemble proteose in their resistance to bacterial attack.

JOHN T. MYERS.

**The influence of carbohydrate on the nitrogen metabolism of bacteria.** NATHAN BERMAN AND LEO F. RETTGER. Yale Univ. *J. Bact.* 3, 389-402 (1918).—The failure of certain organisms to attack protein or other complex nitrogenous foods in a medium containing carbohydrate is due to the accumulation of products which inhibit growth. The N which is required in the cell reproduction of the bacteria in the sugar medium is supplied by relatively simple substances, as for example amino acids and purine bases, which are always present in the ordinary media containing com. peptone or meat ext., although in small amt. The information furnished by the titratable acidity figures is of little value. Reactions which would ordinarily be considered too high apparently had no inhibitive action on continued bacterial development. Culture fluids giving the same titration values may differ markedly in their H-ion concn. As was shown in the present work, a culture giving a Me-red negative test may have a titratable acidity twice as great as one that is Me-red positive. The presence of a carbohydrate in a culture medium may inhibit protein metabolism, depending on the nature of the medium and on the type of the organism. The presence of sufficient buffer in a medium encourages continued N metabolism. A utilizable carbohydrate in a medium has a true "protein sparing" effect providing the H-ion concn. is maintained within suitable limits.

**Biological characteristics of a liquefying paracoli bacillus found in war wounds of the breast of long standing.** GEORGES ROSENTHAL. *Compt. rend. soc. biol.* 81, 110-1 (1918).—This bacillus liquefied coagulated serum and also the coagula from aseptically collected blood and the fluid from sero-fibrinous pleurisy. It failed to liquefy egg albumin, even after prolonged action; casein was readily digested. Cleavage of the liquefied albumins of milk and blood serum reached the stage of amino acid production. Hemolytic action on citrated blood was noted at incubator temp.; hemolysins were also produced at room temp. Killed cultures also exhibited hemolytic action. Hemoglobin media (bouillon, gelose and peptone soln. to which an aq. soln. of human hemoglobin had been added) were readily clarified by the action of the bacillus; this action proceeded more rapidly at incubator than at room temp. Starch, sucrose, mannitol, maltose and lactose were not attacked; slight fermentation of levulose and

glucose occurred after several days. Urine was rendered alk. by the action of the bacillus. A 2:100 glycerol soln. was attacked after several days, but no action on a peptone soln. containing 20:100 of glycerol was noted. Abundant cultures were obtained in 1:300 peptone soln. and in a 1:100 soln. of pure gelatin; it was also possible to obtain cultures in media containing as little as 1:1000 and 1:900 of peptone and gelatin, resp. The bacillus did not produce indole. It is to be classified between the paracoli bacilli and the *Proteus* group; it resembles the latter in its liquefying action and its reducing action on urea and differs in its slight action on sugars, non-coagulation of milk, etc.

H. S. PAINE.

**Note on the production of acid by pneumococci.** GLENN E. CULLEN AND ALAN M. CHESNEY. Rockefeller Institute. *J. Exp. Med.* 28, 289-96(1918).—Actively growing pneumococci produce acid at such a rate that change in the  $p_H$  of the medium parallels change in the rate of growth. The death of the pneumococci is not followed by change in the reaction. Acidification during growth in beef infusion media proceeds until a  $p_H$  of about 7 is reached. At this point growth stops. The increase in the H-ion concn. is not the only origin of the injury to the cell that causes lag in a subsequent culture. The increase in H-ion concn. of the medium is not the sole cause of cessation of growth.

C. J. WEST.

**Optimum hydrogen-ion concentration for the growth of pneumococcus.** K. G. DERNBY AND O. T. AVERY. Rockefeller Institute. *J. Exp. Med.* 28, 345-57(1918).—The optimum H-ion concn. for the growth of the various types of pneumococcus is a  $p_H$  of about 7.8, while the limiting values are 7.0-8.3. Phosphate used in adjusting the reaction of the media retards growth if present in a concn. greater than 0.1 mol. Culture media should, therefore, have an initial reaction between a  $p_H$  of 7.8-8.0 and a total salt concn. of not exceeding 0.1 mol.

## D. BOTANY.

CARL L. ALSBERG.

**Does the temperature coefficient of permeability indicate that it is chemical in nature?** W. J. V. OSTERHOUT. *Bot. Gaz.* 63, 317-20(1917).—O. challenges Stiles and Jørgensen's conclusion (*C. A.* 10, 2914) that permeability is chem. rather than phys. in nature. By his elec. cond. method O. shows the temp. coeff. of permeability to be not far above 1.33, whereas Stiles and Jørgensen claim it to be 2.18-2.22. The latter, if true, would probably indicate a chem. process, since no phys. processes are apt to be involved in this case which have a temp. coeff. as high as 2.

B. HARROW.

**Quantitative measurements of permeability.** WALTER STILES AND INGVAR JØRGENSEN. *Imp. Coll. of Science and Technology. Bot. Gaz.* 65, 526-34(1918).—Polemical. An answer to Osterhout (cf. preceding abstr.).

B. HARROW.

**Absorption of sodium and calcium by wheat seedlings.** H. S. REED. *Bot. Gaz.* 66, 374-80(1918).—Osterhout's theory of antagonism (*C. A.* 10, 2744, 3075) makes it appear that it cannot be applied to solns. of low concns. R. investigated this phase, and further analyzed the plants to det. the amt. of solute taken up. The expts. were conducted on wheat seedlings grown on disks of perforated Al buoyed by glass bulbs in such a way that the Al disk floated at the surface of the soln. Each disk was floated on about 3 l. of soln. in an agate enameled pan. The seeds were germinated in a soln. of the same compn. as that designed for the expt. None but sprouted seeds were used. One of the ratios of Na:Ca in which Osterhout found the greatest amt. of antagonism was the one most favorable for growth. Plants grown in a soln. containing 98 Na:2Ca attained the greatest dry wt. and were larger than any others in the series.

From this soln. the greatest amt. of ash constituents, and the greatest amt. of Na were absorbed.

B. HARROW.

**Transformation of inulin by autohydrolysis in the tubercles of asphodels.** E. COUVREUR. *Compt. rend. soc. biol.* 81, 40-1(1918).—The carbohydrate reserve of the tubers of *Asphodelus cerasiferus* and *A. microcarpus* consists of inulin. When the tubers were mascerated in  $H_2O$  there was obtained in the ext. a reducing sugar which, after investigation by the osazone method, proved to be maltose. This sugar was not pre-existent in the tubers (at least not during the season of the year (summer) when examn. was made), but only appeared in the ext. after a certain length of time.

H. S. PAINE.

**Growth of the rice plant.** S. SUZUKI. Agr. Expt. Station, Govt. of Formosa, *Bull.* 124, 62 pp.(1917).—The object of this study was to det. the development and compn. of the rice plant at successive stages in its growth. Young rice plants grown in a nursery were transplanted on April 1 into plots A, B and C at the rate of 44068 bundles per acre, each bundle containing five plants, and cultivated in the usual way. The complete fertilizers applied to plots A and B were the same except that the N for plot A was from soy bean cake and for plot B from  $(NH_4)_2SO_4$ . Plot C, on somewhat exhausted land, received no fertilizer. The results of this study are assembled in 57 tables. Detns. were made for particular dates in the growth of the plant, thus: April 30, May 10 and 26, June 16 when in full bloom and July 4 when fully ripe. Among the points detd. for these dates and for plants from each plot, A, B and C, are total wt. of the fresh plant; wt. of leaves, stems including sheaths, roots and grain; rate of increase of the wt. in each of these parts; wt. and percentage of water in the plant and in its several parts; wt. of dry matter; rate of increase in the amt. of dry matter in the entire plant and in its several parts; percentage of protein substance, glucose, sucrose, dextrin, starch, pentosans, crude fiber, N,  $P_2O_5$ ,  $K_2O$ ,  $Na_2O$ ,  $CaO$ ,  $MgO$ , and  $Fe_2O_3$ . The percentages of N,  $P_2O_5$ , and  $K_2O$  in the grain at the time of heading out, after flowering and at maturity were detd. in 3 samples. These constituents were also detd. in the chaff or glumes and in the cleaned rice. The rates of increase of N and  $P_2O_5$  were detd. Field and variety tests were made when suggested by the findings, and the products were studied with reference to fertilizer and climatic requirements. All the results of this study are thoroughly discussed.

#### E. NUTRITION:

PHILIP B. HAWK.

NORMAL.

**The dietary deficiency of cereal foods with reference to their content in "anti-neuritic vitamine."** C. VORGTLIN, G. C. LAKE AND C. N. MYERS. *U. S. Pub. Health*

*Repts.* 33, 647-66(1918).—Extensive expts. were carried out on full-grown pigeons and chickens, to study the occurrence of the antineuritic vitamine in foods derived from wheat or corn. The observations made on birds were confirmed by expts. on dogs, hogs, and white mice. The following conclusions were reached: (1) For pigeons an exclusive diet of whole wheat or corn furnishes an adequate supply of antineuritic vitamine. (2) The antineuritic vitamine seems to reside in the peripheral layers and the germ of these seeds, whereas the endosperm is relatively poor in this substance. (3) If wheat and corn foods containing only a small percentage of the peripheral layers and germ of the seed are fed to pigeons or chickens, exclusive of other food, polyneuritic symptoms appear on an average of three weeks after the beginning of the feeding period. The birds can be relieved of their paralysis in a striking way by the subcutaneous administration of a highly concd. prepn. of antineuritic vitamine derived from "whole wheat" bread, yeast, ox liver, rice polishings or beans. (4) The addition of yeast (in amts. used by bakers) in the prepn. of bread from highly milled flour does not prevent the appearance of polyneuritis in birds fed on this food, but prolongs slightly the period of incubation. (5) The addition to highly milled flour or bread made from it, of a small amt. of antineuritic vitamine prepn., will correct this particular dietary deficiency. (6) The total P content of corn and wheat foods is a fairly satisfactory index of the amt. of antineuritic vitamine content in these foods.

G. MCGUIRE.

**Parallel determinations of amylase and dextrose-glycogen of the blood, liver and kidney after feeding.** E. E. BROWN AND C. W. GREEN. *Proc. Am. Physiol. Soc., Am. J. Physiol.* 45, 570(1918).—Sets of animals were fed meals consisting primarily of carbohydrates, carbohydrates and fats, carbohydrates and protein, and protein. The blood, liver, kidney, and muscle of these animals were examd. for carbohydrates by the Lewis-Benedict method and for amylase by the Meyers-Killian method. The animals were killed at intervals during the digestion and absorption of the test meal. The blood and tissue curves were obtained.

G. MCGUIRE.

**Diet experiments bearing on carbohydrate luxus-consumption and wasteful eating.** A. GULICK. *Proc. Am. Physiol. Soc., Am. J. Physiol.* 45, 549(1918).—The purpose of the tests was to det. whether excessive consumption of carbohydrate by a person of the characteristically lean physical type did not stimulate the organism to oxidize away a large part of the excess supply of fuel. The conclusions were: (1) Minimum food requirements were somewhat greater than would be expected from the activities. (2) Upon eating persistently more than was relished the weight was gradually raised. (3) If there is a luxus factor it is not overwhelmingly large. (4) If a luxus oxidation occurs at all, its effect is ended within 14 hours after taking food. (5) From an economic standpoint, the increased fuel expenditure found in these expts. with a high diet and moderate activities was a pure waste.

G. MCGUIRE.

**Utilization of the various saccharides in the metabolism of the central nervous system.** ELSE HIRSCHBERG. *Z. physiol. Chem.* 101, 248-54(1918); *J. Chem. Soc.* 114, I, 416-7.—Maltose and sucrose are not utilizable for the maintenance of the metabolic processes of the surviving spinal cords of frogs. Dextrose and levulose have about equal power in maintaining metabolism in the resting state, while lactose has less and galactose considerable more, probably due to the participation of the latter substance in the compn. of the nervous tissue. During excitation, the consumption of dextrose by the tissue greatly exceeds that of any other saccharide other than galactose. Dextrose is therefore the best material to supply for the rapid production of power for the use of nervous tissues.

C. J. WEST.

**Nitrogenous metabolism of the central nervous system.** ELSE HIRSCHBERG AND HANS WINTERSTEIN. *Z. physiol. Chem.* 101, 212-22(1918); *J. Chem. Soc.* 114, I,

416.—The isolated spinal cord of the frog contains in the fresh material 1.3% N and 1.25% in cords freed from the outer membranes. The N content is unaltered by preservation of the cords in air or O, but falls rapidly when immersed in oxygenated saline soln. The addition of a trace of a Ca salt to the saline soln. increases the rate of loss of N from the cord; K salts decrease it. Treatment with 4% EtOH practically arrests nitrogenous metabolism; elec. stimulation increases it nearly 4 times. The catabolic action is an oxidative one, because it fails to occur in the absence of free O.

C. J. WEST.

#### ABNORMAL.

**Digestion of the proteins of cooked meat in dogs with ligatured carotid arteries.** E. ZUNZ. *Biochem. J.* 12, 42–59(1918).—Ligature of carotids results in a meat meal remaining in the stomach for a longer time than under normal conditions. Z. considers this due to an altered blood supply to the stomach.

B. HARROW.

#### F. PHYSIOLOGY.

ANDREW HUNTER.

**Analysis of normal Filipino urine.** ISABELO CONCEPCION. *Philippine J. Sci.* 13B, 285(1918).—The 24-hr. urine of Filipinos has a small vol., and is low in: total N (3.05 to 12.63 g.), urea N (calcd. as % of total N), uric acid (av. 0.376 g.), and chlorides (av. 5.86 g. NaCl). "The  $\text{NH}_3$ , the creatinine, the undetd. N, and the ratios  $\text{N}:\text{P}_2\text{O}_5$  and  $\text{N}:\text{S}$  are in accord with the low-N values of the Filipino dietary." J. S. H.

**Physiological basis of thirst.** WALTER B. CANNON. *Harvard Univ. Proc. Roy. Soc. London* 90B, 283–301(1918).—The Croonian lecture for 1918. Thirst is due directly to a relative drying of the mucosa of the mouth and pharynx; true thirst depends upon the fact that the salivary glands, which keep the buccal and pharyngeal mucosa moist, require water for their action. "The water supply is maintained because we avoid, or abolish, by taking water or aq. fluid, the disagreeable sensations which arise and torment us with increasing torment if the salivary glands, because of a lowering of the water content of the body, lack the water they need to function, and fail therefore to pour out their watery secretion in sufficient amt. and in proper quality to keep moist the mouth and pharynx."

JOSEPH S. HEPBURN.

**Mechanism and control of fibrillation in the mammalian heart.** J. A. MACWILLIAM. *Proc. Roy. Soc. London* 90B, 302–23(1918).—The paper is mainly physiological. The control of ventricular fibrillation by means of certain compds. ( $\text{SrCl}_2$ , urethan, adrenaline, hirudin, and pilocarpine) is described.

J. S. H.

**The isolation and identification of the thyroid hormone.** The physiological action of the thyroid. E. C. KENDALL. *Proc. Am. Physiol. Soc., Am. J. Physiol.* 45, 540 (1918).—The iodine-containing compd. of the thyroid was isolated and identified as hydrotriiodooxyindolepropionic acid. This substance will relieve all symptoms of cretinism and myxedema to the same extent as desiccated thyroid. It seems probable that the physiological activity of the substance is due to the action between itself and the amino acid. It was found that the animal organism could utilize the substance when the carbonyl group had reacted forming a nitrogen derivative, and this reaction presumably is involved in the deaminizing action of the substance in the body. However, replacing the H of the imino group with derivs. renders the substance inert within the animal organism. This action also shows that when the imino group cannot function, the entire compd. is rendered physiologically inert.

G. MCGUIRE.

**The tension of the blood gases in the blood entering and leaving the lungs.** R. G. PEARCE AND A. NICHOLSON. *Proc. Am. Physiol. Soc., Am. J. Physiol.* 45, 550 (1918).—"As long as the minute vol. of the circulation and the respiration increases directly with the metabolism, the difference between the tensions of the gases in the

blood entering and leaving the lungs remains approx. const." During acute exercise, however, this equil. is disturbed and this difference increases progressively. "The progressive increase in the difference in the tension of gases entering and leaving the lungs is brought about by the hyperpnea which reduces the tension of the  $\text{CO}_2$  in the alveolar air below that normally present or expected, and to the very rapid and disproportionate increase in the tension of the  $\text{CO}_2$  in the blood entering the lungs. The methods employed for the estn. of the tension of the respiratory gases in the blood entering and leaving the lungs at various levels of metabolism afford a means of judging the heart's reaction to and capacity for acute work." G. MCGUIRE.

**The effect of water and sodium bicarbonate on the gastric secretion.** C. E. KING AND W. W. HANFORD. *Proc. Am. Physiol. Soc., Am. J. Physiol.* 45, 562(1918).—From expts. carried out on Pavlov dogs the following observations and conclusions were made: (1) Water excites the flow of gastric juice. (2) Water-starved dogs secrete no appetite juice when shown water. (3) The acidity of the gastric juice runs parallel with the rate of secretion until a max. is reached. This max. varies in different dogs but is near 0.5% HCl. (4) Water given with meals or during digestion results during the following hour in an increase in the amt. of juice secreted over that which would be secreted on the administration of either water or meat alone. This also holds true for 1%  $\text{NaHCO}_3$ . (5) 1%  $\text{NaHCO}_3$  excites the flow of gastric juice, being somewhat less effective than distd. water. (6) The acidity of alkali juice when alkali is introduced into the empty stomach is on an average a little lower than that of water juice, but not materially different when the alkali is given with meals or during digestion. This refers to total acidity. The combined acidity of alkali juice is a little higher than that of water juice. (7) Water and alkali juices possess about the same peptic activity, but both are much less active than meat juice. (8) No injurious effects were noted on the continued administration of 1%  $\text{NaHCO}_3$ . G. MCGUIRE.

**The effect of water on gastric secretion.** G. F. SUTHERLAND. *Proc. Am. Physiol. Soc., Am. J. Physiol.* 45, 563(1918).—The stimulating effect of water on the gastric secretion was studied when the water was introduced (1) into Pavlov dogs by intravenous infusion, (2) into the small intestine without the possibility of regurgitation into the stomach, (3) into man and dogs by stomach tube. A stimulating effect was observed in the above cases. Water introduced into the gastric intestinal tract has a greater stimulating effect than by intravenous infusion. There is a periodicity in the gastric secretion in starvation, periods of low activity alternating with periods of "spontaneous increased activity." In pups and kittens the gastric glands are not able to secrete free HCl until about the time of birth. In guinea pigs this power is developed earlier. G. MCGUIRE.

**Blood regeneration after simple anemia. I. Curve of regeneration influenced by dietary factors.** C. W. HOOPER AND G. H. WHIPPLE. *Proc. Am. Physiol. Soc., Am. J. Physiol.* 45, 573(1918).—These expts. indicated "that blood regeneration after simple anemia of a definite grade can be influenced at will by various dietary factors. The curve of blood regeneration on a meat diet is very rapid, a matter of days or weeks, while the curve on a diet rich in carbohydrates is very slow." Fe in the form of Bland's pills had no appreciable effect on the curve. **II. Curve of regeneration influenced by starvation, sugar, amino acids, and other factors.** *Ibid* 576. (1) *Starvation*: The curve of pigment vol. drops to about one-third normal after the unit bleeding. Beginning the first week of repair a slow but steady rise in the curve develops, which continues through the following weeks (3 to 4). No marked differences in blood regeneration, under these experimental conditions, were observed in normal, bile fistula, or splenectomized dogs. (2) *Sugar feeding*: "A definite amt. of cane sugar or glucose, or a mixt. of the two sugars (50 to 125 g.) was dissolved in a uniform amt.

of water and given by stomach tube." The curve shows an initial rise in the first week, similar to the starvation curve, but after that there is no gain and often a slight loss. The effects are discussed of gliadin, hemoglobin, gelatin, the monoamino and the diamino acid fractions of gelatin, and also of amino acids in general, on the regenerative curve.

G. MCGUIRE.

**Note in regard to the amount of sugar normally in the blood of cats.** E. L. SCOTT. *Proc. Am. Physiol. Soc., Am. J. Physiol.* 45, 578(1918).—After further expts. on over 100 cats, the author reaffirms his figures, published in 1914, of 0.069 g. of sugar per 100 g. of blood. Cf. *C. A.* 8, 2893.

G. MCGUIRE.

**Residual nitrogen of the blood.** J. FEIGL. *Arch. exp. Path. Pharm.* 83, 168–89, 190–203, 257–70, 271–98; *Physiol. Abstracts* 3, 247–8.—Elaborate statistical studies of residual N in the blood of 750 normal fasting people of ages varying from infancy to extreme old age. As age advances the residual N increases as a whole, and this is also true for its components urea, creatinine, creatine and uric acid.

C. J. WEST.

**Guinea-pig serum.** J. FREUND. *Biochem. Z.* 86, 421–5(1918); *Physiol. Abstracts* 3, 375.—Guinea-pig blood contains 5% proteins. F. calls attention to the constancy of the water content of the serum.

C. J. WEST.

**Determination of the quantity of secreting tissue in the living kidney.** C. K. WATANABE, JEAN OLIVER AND THOMAS ADDIS. Stanford Univ. Med. School. *J. Exp. Med.* 28, 359–76(1918).—Under the strain induced by the administration of urea, it is possible to demonstrate the relation between the degree of anatomical damage in the kidney and the degree of defect in the urea-excreting capacity induced by uranium. The closest function was obtained when the ratio between the urea content of the urine and of the blood was used as the measure of function.

C. J. WEST.

**The non-influence of rise in body temperature induced by drugs upon the protein quotient and the enumeration of white corpuscles.** FLORENCE MCCOY HILL. Univ. Cal. *J. Pharmacol.* 12, 1–17(1918).—Fluid ext. of ergot in doses of from 1 to 1.5 cc. per kg. body wt. administered intravenously to rabbits induced a steady rise in body temp. from 1.5 to 2.2. Higher doses proved fatal. Ca lactate in doses of from 5 to 8 cc. of a 1:20 soln. administered intravenously to rabbits caused an initial fall of from 0.4 to 0.6° in temp. accompanied in the higher doses by symptoms of Ca poisoning. This was succeeded by a strong rise of from 1.5 to 2.5° and disappearance of the symptoms of poisoning. The expts. show that the aseptic fever induced by these drugs causes no alteration in the globulin content of the blood nor does any alteration of note occur in the leucocyte count.

C. J. WEST.

**Liberation of the internal secretion of the thyroid gland into the blood.** J. M. ROGOFF. Western Reserve Univ. *J. Pharmacol.* 12, 193–206(1918).—An attempt was made to detect in the blood coming from the thyroid glands of 3 dogs, a physiologically active secretion by feeding the dried blood to tadpoles. One dog, whose thyroid glands were rich in colloid and had a good I content, yielded evidence of an active secretion in the blood collected from the glands during massage and during stimulation of the cervical sympathetic nerves. This result yields no evidence of the existence of secretory nerves to the thyroid for it is not possible to know the rate of liberation of the secretion and an increased concn. of the secretion in the thyroid blood alone can not be taken as evidence of increased liberation. Two dogs whose thyroid glands were hyperplastic and contained no detectable I yielded negative results.

C. J. WEST.

**Chemical stimulation of the intestinal glands.** Z. TOMASZEWSKI. *Pflüger's Archiv* 170, 260–312; *Physiol. Abstracts* 3, 252–3.—Expts. were carried out on dogs with gastric and duodenal fistulas. Psychic influences were excluded as far as

possible. Aq. or HCl exts. of stomach, various parts of small and large intestine, and pancreas were made and injected intravenously or subcutaneously. Very little effect was obtained by intravenous injection but after subcutaneous injection a flow of juice began in about 15 min. and lasted 1-2 hours, as much as 350 cc. of juice being collected in that time. In some cases the vagi were cut or atropine given, but the result was the same. The vol. of juice obtained was proportional to the solid content of the ext. used. Edkin's expts. were repeated but in those cases where secretion of juice was observed, T. explains it as due to squeezing out of juice as the result of muscular contractions of the stomach wall. In any case the effect of pyloric ext. was no more marked than that of an ext. of fundus. The substance responsible for the secretion is an organic compd., stable at 100°, slowly decomposed at 130°, or by the action of pepsin, but not of trypsin. It is not identical with vasodilatin, since Witte peptone does not cause the secretion. The activity of the exts. is increased by treatment with 80% alc. but is slowly destroyed by abs. alc. (EtOH or MeOH). It is not extd. by Et<sub>2</sub>O, CHCl<sub>3</sub> and is not pptd. by colloidal Fe or HgCl<sub>2</sub>, but  $\frac{3}{4}$  of the activity is lost by pptn. of the ext. with phosphotungstic acid.

C. J. WEST.

**The pseudo-crystallization process of fibrin formation.** E. HEKMA. *Nederl. tijdschr. v. geneesk.* 1918, I, 1386; *Chem. Weekblad* 15, 1108.—The physical theory of blood coagulation is upheld, namely, that it is due to transition of the fibrin from the hydrosol to the hydrogel state. This is ascribed to the formation of acid compds., as nucleoproteins, globulins and phosphatides, from the corpuscles and leucocytes as they sep. from the plasma. These withdraw alkali and H<sub>2</sub>O from the plasma till the fibrin is changed from sol to gel. This appears under the microscope as a pseudo-crystn., but under the ultramicroscope as the joining of minute particles in the direction of their length to form needle-shaped aggregates, which grow into threads.

## G. PATHOLOGY.

H. GIDEON WELLS AND ANDREW HUNTER.

**Studies on cholesterol.** V. The blood cholesterol in malignant disease and the effect of radium treatment on blood cholesterol. G. LUDEN. *Proc. Am. Physiol. Soc., Am. J. Physiol.* 45, 580(1918); cf. *C. A.* 12, 1213.—The examn. for cholesterol of 1069 samples of blood, including human, goat, gopher, and dog, taken under various conditions, led to the following conclusions: (1) The high blood cholesterol values in carcinoma are not due to cell destruction since they are lowered by radium treatment, but they are due to a disturbance of cholesterol metabolism. (2) The disturbance of cholesterol metabolism may be but evidence of a low rate of basal metabolism. (3) Radium, by lowering the blood cholesterol values, alters the chemical compn. of the blood, a fact which has not hitherto been taken into account in the study of the effects of radium treatment. (4) The administration of the thyroid hormone affects the blood cholesterol values in a manner similar to that of radium treatment and may, therefore, be expected to be equally beneficial to patients suffering from carcinoma. Further investigations are being carried out to det. the effect of thyroxin in carcinoma.

G. MCGUIRE.

**Azotemia and the Bordet-Wassermann sero-reaction.** D. SOTIRIADES. *Compt. rend. soc. biol.* 81, 276(1918).—Azotemia, when occurring coincidently with syphilis, inhibited the Bordet-Wassermann reaction. When azotemia disappeared or diminished following treatment the sero-reaction became positive; diminution or disappearance of azotemia was detd. by aid of the Ambard ureosecretory coeff. Nitrogenous substances probably inhibit the sero-reaction by means of a mechanism the nature of which is not understood.

H. S. PAINÉ.

**Monophagism, pellagra and scurvy.** G. VOLPINO. *Annali d'igiene Rome* 28, 280(1918); *J. Am. Med. Assoc.* 71, 1096.—Among the experiences reported was the finding that pellagrins responded with a pronounced local and general reaction to injections of exts. of maize. Including reports by others there were 136 positive and 11 doubtful or negative responses in 147 pellagrins, while positive responses were obtained in only 33 out of 130 non-pellagrins. V. regards these findings as testifying to sensitization of the pellagrins. The work is to be continued. L. W. RIGGS.

**Progressive muscular dystrophy.** FRANCIS H. MCCRUDDEN. Boston. *J. Am. Med. Assoc.* 70, 1216(1918); cf. *C. A.* 12, 827.—The myasthenia of this disease is due to hypoglycemia, and the hypoglycemia and fat deposition to impaired glycogenesis, the carbohydrate of the food being probably changed largely to fat instead of to glycogen. The impaired glycogenesis is due to suprarenal or other endocrine disease.

L. W. RIGGS.

**Cholesterol in joints.** M. LOEPER AND G. VERPY. *Bull. soc. med. hopitaux* 42, 496(1918); *J. Am. Med. Assoc.* 71, 1254.—Cholesterol deposits were found in the connective tissues, synovia, synovial fluid, and aorta of a patient with deforming polyarthritis who had succumbed to aortitis; also in a tumor and hygroma, resp., in two other patients with the same disease. To det. the nature of a deforming rheumatism it may be necessary to apply chem. tests to the deposits in the joints. Treatment would vary according as the tests revealed singly or combined carbophosphates, oxalates, uric acid or cholesterol.

L. W. RIGGS.

**Experimental paratyphoid B fever. Mechanism of immunity. Vaccination by the buccal route.** A. BESREDKA. *Compt. rend.* 167, 212-4(1918).—Expts. led to the following conclusions: Vaccination *per os* by means of heated cultures, after sensitization by bile, renders the animal resistant to paratyphoid infection. This acquired immunity, as well as that which the animal naturally possesses, depends upon local intestinal immunity.

L. W. RIGGS.

**Thermo-precipitin diagnosis of tuberculosis.** A. FORNERO. *Annali ostetricia e ginecologia* 19, 87(1917); *J. Am. Med. Assoc.* 71, 1256.—Civalleri first called attention to the zonal reaction of pptn. when an ext. of tuberculous sputum obtained with  $\text{CHCl}_3$  is brought into contact with anti-tuberculosis serum. F. proceeds by making an emulsion of the sputum with an equal vol. of physiologic salt soln., and after boiling and filtering, places it in contact with tuberculosis immune serum. The resulting pptn. reaction does not occur with normal or syphilitic serum. This technic renders the action more specific than without the heating. The immune serum found most striking in its effects came from an ass hyperimmunized with killed and live human tubercle bacilli. Four cc. of  $\text{CHCl}_3$  are poured on 2 cc. of sputum and kept 3 hrs. at  $37^\circ$ . The  $\text{CHCl}_3$  is then decanted and 4 cc. of the salt soln. are added to what is left in the tube, the mixt. agitated and the resulting emulsion boiled in the water bath for 2 min. It is then filtered cold. A tube 5 cm. by 6 mm. is filled half full of physiologic salt soln. containing the immune serum and a layer of the filtrate floated on with a pipet. The reaction reaches its height in 15 or 20 min. Positive results were obtained in 94% of all certain cases tested, and only in 7% of the nontuberculous. The test can be applied to urine pus or other body fluids and with much smaller amts. of fluid, keeping the proportions the same.

L. W. RIGGS.

**Colorimetric measure of the syphilitic infection.** ARTHUR VERNES. *Compt. rend.* 167, 383-5(1918).—In the presence of an appropriate colloidal suspension syphilitic serum flocculates while the same amt. of normal serum does not. This allows the detn. of the digression from stability which may be measured by the usual opacity methods, or, more conveniently by the color. If one imagines a substance which has at the same

time a dispersive (antiflocculant) and a hemolytic action, and of which the dispersive power may be utilized on condition of losing at the same time a proportional part of its hemolytic power, then in place of estg. directly the digression from stability by the degree of opacity, this can be measured indirectly from the degree of hemolysis by means of a colorimetric scale. Many substances are able to play this role, notably the serum of the hog. The technic is described in detail. Not only are the tubes with normal serum red and the tubes with syphilitic serum decolorized from a red bottom upwards, but the cells not dissolved give rise to tints intermediate between the white and red max. and constitute a series of syphilimetric indexes of the highest importance for the serodiagnosis, prognosis and treatment of syphilis.

L. W. RIGGS.

**Significance of lactic acid in stomach.** A. RODELLA. *Correspondenz-Blatt für Schweizer Aerzte* 48, 1210(1918); *J. Am. Med. Assoc.* 71, 1445.—R.'s studies demonstrated that sterile substances covered with pure concd. HCl, if they are not destroyed, remain sterile. But infected albuminous substances, in solid form and in not too small fragments, covered with HCl, not only fail to become sterile but undergo at body temp. strong fermentation. The products of fermentation may include lactic acid. This responds to the Uffelmann test even in the presence of HCl. Neither the lack of HCl nor the presence of a tumor and resulting stagnation are absolutely necessary for the production of lactic acid. It can occur wherever there is retention of stomach content, plus the presence of substances which bind the HCl or which protect the fermentable matter against the action of HCl. When these conditions are realized lactic acid may be formed abundantly in the stomach even without cancer. These conclusions are supported by Prou's findings of lactic acid in the fasting stomachs of 81 out of 300 cases of nonmalignant stomach disease.

L. W. RIGGS.

**Urinary siderosis.** Hemosiderin granules in the urine as an aid in the diagnosis of pernicious anemia, hemochromatosis and other diseases causing siderosis in the kidney. PEYRON ROUS. Rockefeller Inst. *J. Exp. Med.* 28, 645-58(1918).

C. J. WEST.

**Urobilin elimination in the normal and anemic dog.** HARRY DUBIN. Univ. Penn. *J. Exp. Med.* 28, 313-8(1918).—The output of urobilin is increased in exptl. trypanosome anemia presumably as the result of increased blood destruction. The administration of salvarsan during the anemic period, if it checks the blood destruction, reduces the urobilin elimination, but this result does not follow unless the blood picture improves. Splenectomy during the period of anemia does not cause a decrease in urobilin elimination.

C. J. WEST.

**Nitrogen metabolism and acidosis after the transplantation of a ureter into the duodenum.** K. GORO. *J. Exp. Med.* 27, 449-58(1918).—After transplantation of the right ureter into the intestine, or after ligation of the right ureter in dogs, an increased output of N in the urine is noted. In the former cases, there was N retention but no disturbance of the CO<sub>2</sub> content of the blood. The significance of this is probably an increased tissue catabolism. Removal of the left kidney subsequent to the above operative procedure resulted in renal insufficiency with N retention and acidosis, which terminated fatally, accompanied by the characteristic symptoms. These results demonstrate that the transplantation of the right ureter into the duodenum had so interfered with the function of the right kidney as to render it inadequate for maintaining renal function after removal of the left.

C. J. WEST.

**Paradoxical reflex secretion in chronic atropine poisoning.** The histological changes in the pancreas as a result of chronic poisoning in animals. H. ARIMA. *Arch. Exp. Path. Pharm.* 1918, 1-116, 157-67; *Physiol. Abstracts* 3, 275.—Reflex secretion of abundant saliva occurs in cats and dogs after repeated injections of atropine and

continues for weeks and months if the injections are continued for that time. It passes off in 10-24 hours after the final injection. The chorda tympani and sympathetic nerves are usually excitable, but in some cases the former was not even at the height of paradoxical secretion. The drug is believed not to act on the gland directly, but indirectly through the saliva center in the bulb, the excitability of which is raised. The gland cells manifest the usual signs of increased activity. In new born kittens of atropinized mother the same occurs. Atropine has no effect on the development of the salivary glands. No opportunity has yet occurred of testing the question on the pancreas in a fistula dog but histological evidence is adduced that this organ, like the salivary gland, is highly active in chronic atropine poisoning. C. J. WEST.

**Antibody production after partial adrenalectomy in guinea pigs.** F. L. GATES. Rockefeller Inst. *J. Exp. Med.* 27, 725-38; *Physiol. Abstracts* 3, 330.—Seven-eighths of the adrenal tissue was removed without causing any symptoms of adrenal insufficiency. No effect upon the production of antibody was observed following this operative procedure and hence it is concluded that the adrenal glands are not one of the important sources of typhoid agglutinins or of hemagglutinins or hemolysins and that they play no essential part in the mechanism whereby these antibodies are produced and maintained in the body. C. J. WEST.

**Experimental chemical pneumonia.** MARTHA WOLLSTEIN AND S. J. MELTZER. Rockefeller Inst. *J. Exp. Med.* 28, 547-50(1918).—Concns. of chloramine-T, more dilute than those which are well borne by the nasopharyngeal mucosa, are injurious to the pulmonary tissue when introduced into the bronchi in large volume. The lesions are of the nature of an extensive bronchopneumonia. These lesions differ from infectious pulmonary inflammation only in their sterility. C. J. WEST.

**Effect of intrabronchial insufflation of solutions of some inorganic salts.** MARTHA WOLLSTEIN AND S. J. MELTZER. Rockefeller Inst. *J. Exp. Med.* 28, 551-8(1918).—Intrabronchial injections of isotonic as well as hypertonic solns. of NaCl or even of distd. H<sub>2</sub>O cause no pulmonary lesions. HgCl<sub>2</sub> (1-10,000) causes marked pulmonary lesions consisting of congestion, formation of thrombi and hemorrhage. Mg salts apparently tend to cause moderate pulmonary lesions, especially true of MgSO<sub>4</sub>. C. J. WEST.

**Specific poison in the liver extracts of rabbits inoculated with typhoid and prodigiosus bacilli intravenously.** JULIA T. PARKER. Columbia Univ. *J. Exp. Med.* 28, 571-83(1918).—The livers of rabbits inoculated with cultures of *Bacillus typhosus* or *Bacillus prodigiosus* under certain conditions contain a toxic substance extractable with salt soln. When injected intravenously into normal rabbits, they develop symptoms resembling those of anaphylactic shock and succumb. The lethal dose is far smaller than that of normal liver ext. The livers of rabbits injected with typhoid antigen also yielded a toxic ext. Boiling as well as filtration through a Berkefeld filter only partially detoxicates the ext. Tolerance to 1 or 2 lethal doses may be induced by cautious immunization. Rabbits actively immunized to *Bacillus typhosus* or *B. prodigiosus* usually resist 1 lethal dose of the homologous liver poison and animals tolerant to the typhoid liver poison resist 1 minimum lethal dose at least of *B. typhosus*. Typhoid immune serum is not detoxicating either *in vivo* or *in vitro* for the typhoid liver poison. The liver poisons are specific. C. J. WEST.

**The stability of the acid base equilibrium of the blood in naturally nephropathic animals and the effect on renal function of changes in their equilibrium.** I. A study of the acid base equilibrium of the blood in naturally nephropathic animals and of the functional capacity of the kidney in such animals following an anesthetic. WILLIAM DEB. MACNIDER. Univ. N. Car. *J. Exp. Med.* 28, 501-16(1918).—The naturally

acquired chronic glomerulonephropathics of the dog are not due to an acid intoxication. Such an injury renders the acid base equilibrium of the animal unstable and susceptible to an agent such as an anesthetic which tends to reduce an acid intoxication. When naturally nephropathic animals are anesthetized with Grehan's anesthetic, the principal ingredient of which is  $\text{CHCl}_3$ , the animal develops an acid intoxication and becomes anuric and non-responsive to diuretic substances. D. A study of the efficiency of an alkali to protect the naturally nephropathic kidney against the toxic effect of an anesthetic. *Ibid* 517-28.—A 0.9% soln. of  $\text{NaCl}$  when given intravenously to anesthetized animals is not effective in preventing the development of an acid intoxication and the associated kidney injury. A soln. of  $\text{Na}_2\text{CO}_3$ , equimol. with a 0.9% salt soln., confers a variable degree of protection to the kidney. This degree is associated with the ability of the soln. to maintain a normal acid base equilibrium of the blood of the anesthetized animal. C. J. WEST.

## H. PHARMACOLOGY.

ALFRED N. RICHARDS.

The chemotherapeutics of antimony. M. TSUZUKI. *Schweiz. Chem.-Ztg.* 2, 17-22, 36-40(1918); *J. Soc. Chem. Ind.* 37, 282A.—The chemotherapeutics of Sb are compared with those of As. Quinquevalent Sb compds. are inert as compared with the trivalent derivs., just as in the case of As. Sb compds. differ from As in that no immunity to Sb compds. due to acclimatization is acquired either by the blood parasites or by the animal organism. The toxicological properties of Sb and As are very similar. The therapeutic properties of corresponding derivatives of Sb and As show no parallelism either in character or degree. Many Sb compds. show pronounced selective activity in regard to trypanosomes and spirochetes, being more active toward the former. The As compds. do not have this characteristic. Observations regarding the influence of the constitution of the org. portion of the mol. on the therapeutic or toxic properties of As compds. are not valid for the corresponding Sb compds. These differences in the relation between constitution and activity of similar compds. may be due to the greater ease with which Sb is split off from its org. derivatives. For the same reason it is more difficult to suppress the poisonous properties of Sb by org. combination. Certain combinations of As and Sb derivs. have shown useful results.

G. MCGUIRE.

The effects of injecting acacia. W. J. MEEK AND H. S. GASSER. *Proc. Am. Physiol. Soc., Am. J. Physiol.* 45, 548(1918).—From a series of expts. on animals the following conclusions were reached. "Injections of large amts. of 20% acacia have practically no effect on blood pressure other than the mechanical one of increasing the blood vol. The heart rate is not influenced other than that due to the slightly raised blood pressure. After hemorrhage acacia seems to maintain blood pressure better than salt solns. Respiration is unaffected. The urinary secretion after acacia can be stimulated by sodium nitrate apparently as well as normally. An animal under ether may have acacia injected until the blood in a 10% soln. with no symptoms of disturbance. Intact animals have had their blood made up to 4% acacia with no unfavorable symptoms. Acacia leaves the blood stream in the early stages at the rate not exceeding 10% per hour. The rate soon slows and fairly large amts. of acacia may be found in the blood 2 days later. A pentose reaction may be obtained from the urine an hour after the injection of acacia."

G. MCGUIRE.

Restorative effects of salts of magnesium and calcium after lethal doses of sodium oxalate. FREDERICK L. GATES. *J. Exp. Med.* 28, 305-12(1918); cf. *C. A.* 12, 186.

C. J. WEST.

Pharmacological and therapeutic study of benzyl alcohol as a local anesthetic. DAVID I. MACHT. Johns Hopkins Univ. *J. Pharmacol.* 12, 263-79(1918).—Benzyl

alc. possesses powerful local anesthetic properties and a very low toxicity as compared with other well-known local anesthetics. Its use has been demonstrated in practical surgery. The minimum lethal dose is about the following: mice, 1 cc. per kg.; rats, 1 to 3 cc.; guinea pigs, 1 to 2.5 cc.; cats, 1 cc. per kg. C. J. WEST.

The toxicity of the venom of the Mexican (Durango) scorpion as compared with that of the Chinese scorpion. SEIKO KUBOTA. Johns Hopkins Univ. *J. Pharmacol.* 12, 447-89(1918).—The amt. of extractive substance contained in the poisonous glands of different species of scorpion and that of the alc.-insol. toxic matter of the ext. appears to differ in different species. Mexican sting contains more than the Chinese. The active principle of the ext. seems to be of protein nature, is sol. in saline soln. and less sol. in pure water, but is insol. in abs. alc. or ether. The active principle of the Mexican extract is affected very little by drying for a long time, but when preserved at room temp. exposed to sunlight it undergoes putrefaction and loses its convulsant character. It is not affected by heating to 100° for a short period but is destroyed after 30 min. Prolonged action of alc. does not destroy the principle, but acids and alkalis destroy it, alkalis acting more destructively. The active principle of the Chinese ext. when muscular twitching is taken as the indicator, is more resistant to treatment by chem. and physical means. The minimum fatal dose of the venom for mice is about 0.015 mg. per g. body wt. in case of the Mexican scorpion and 1.5 mg. in the Chinese one. For frogs the values are 0.01 to 0.05 in the former and 0.3 to 1.0 in the latter. The symptoms produced by the two seem to differ in certain points. Death in mice and guinea pigs seems mainly to be due to suffocation which may be considered to be caused by the convulsion and paralysis of the respiratory app. and in frogs to a central and peripheral paralysis. The ext. raises blood pressure, acting upon the motor app. of the heart. It increases the tonus and rhythmic movements of smooth muscles. It has a hemolytic action upon both nucleated and non-nucleated blood corpuscles.

C. J. WEST.

Tonus waves from the sino-audicular muscle preparation of the terrapin as affected by adrenaline. CHARLES M. GRUBER AND CASPAR MARKEL. Univ. of Colo. *J. Pharmacol.* 12, 43-51(1918).—Adrenaline in diln. of 1:150,000 to 1:174,000,000 causes a disappearance of the tonus waves observed in the sino-audicular muscle prep. of the terrapin. It causes simultaneously an increase in the force and amplitude of contraction. After the injection of strong solns. a longer time is necessary for the reappearance of the tonus waves than with dil. solns. O in either case hastens the reappearance of the oscillations. This may be merely a matter of hastening the oxidation of the adrenaline.

C. J. WEST.

Tonus waves in the terrapin auricles as affected by pilocarpine, atropine and adrenaline. CHARLES M. GRUBER AND CASPAR MARKEL. Univ. of Colo. *J. Pharmacol.* 12, 53-7(1918).—Pilocarpine-HCl has a marked effect upon the contractions of the heart, almost completely stopping them, but has no effect on the tonus waves. Atropine sulfate increases the general tonus of the heart when injected into the soln. in which the muscle is contracting, either in the normal solution or following the administration of pilocarpine. Adrenaline or its hydrochloride causes a disappearance of the tonus waves in the atropinized heart as it does in the normal heart.

C. J. WEST.

Detoxifying action of sodium salt on potassium salt in the guinea pig. SAMUEL AMBERG AND HENRY F. HELMHOLZ. O. S. A. Sprague Memorial Inst. *J. Pharmacol.* 12, 19-34(1918).—Guinea pigs survive the intravenous injection of otherwise fatal doses of KCl and  $K_2SO_4$  if these are administered in mixts. of NaCl. The same effect is noted when  $Na_2SO_4$  is added to the KCl soln. The effect is, however, not quite so marked. An equal concn. of AcONa does not afford any protection against the KCl

intoxication. The protection offered by NaCl against  $\text{NH}_4\text{Cl}$  is somewhat doubtful; at any rate it is much less marked than that against KCl. The presence of 50% glucose in the KCl soln. protects the animals very markedly. A usual fatal dose of KCl or  $\text{K}_2\text{SO}_4$  injected soon after an injection of 5% NaCl is tolerated, while a previous injection of 0.55% of NaCl protects not at all or only very rarely. Where a previous injection of  $\text{Na}_2\text{SO}_4$  is tolerated it may also protect against KCl. The previous injection of NaCl seems to protect against  $\text{NH}_4\text{Cl}$ . The intravenous injection of 10% NaCl soln. in proper dosage produces a clouding of the crystalline lens. This cloudiness appears within about 20 min. and disappears in the course of about 4 hours.

C. J. WEST.

**Transformation of tetrahydronaphthalene (tetralin) in the animal body.** G. SCHROETER AND K. THOMAS. *Z. physiol. Chem.* 101, 262-75 (1918); *J. Chem. Soc.* 114, I, 418.—Tetrahydronaphthalene fed to a dog is absorbed and eventually excreted in combination with urea. The existence of 4 compds. of tetrahydronaphthalene and urea is theoretically possible, and the authors have succeeded in prepg. all of them by the interaction of KCNO on the respective amines in  $\text{H}_2\text{O}$ . *ar-Tetrahydro- $\alpha$ -carbamidonaphthalene*,  $\text{C}_{10}\text{H}_{14}\text{ON}_2$ , crystallizes in square plates from alc., soften at  $198^\circ$  and melts at about  $206^\circ$  (quickly heated, at  $212^\circ$ ). *ar-Tetrahydro- $\beta$ -carbamidonaphthalene*, needles, m.  $134^\circ$  (decompn.). *ac-Tetrahydro- $\alpha$ -carbamidonaphthalene*, needles, m.  $210.5^\circ$ . *ac-Tetrahydro- $\beta$ -carbamidonaphthalene*, needles, m.  $183^\circ$ . Comparison of the natural product with these compds. shows that tetralin in its passage through the body is converted into *dl-ac-tetrahydro- $\alpha$ -carbamidonaphthalene*. In the prepn. of the *ar- $\beta$* -compds., a small amt. of a substance was obtained in the form of needles, which did not melt below  $245^\circ$  and possessed the compn. of *di-ar-tetrahydro- $\beta$ -naphthylcarbamide*,  $(\text{C}_{10}\text{H}_{12}\text{N})_2\text{CO}$ .

**Treatment of amebic dysentery with Chaparro amargosa (Castela Nicholsonii of the family Simarubaceae).** ANDREW WATSON SELLARDS AND MONROE ANDERSON McIVER. Harvard School of Trop. Med., and Mass. Gen. Hospital. *J. Pharmacol.* 11, 331-56 (1918).—Several members of the family Simarubaceae contain bitter substances. These have been examd. chemically and several substances giving color reactions have been obtained but as yet have not been identified. The evidence points to the presence of a glucoside. In the treatment of 4 cases of amebic infection with the product, the immediate results were distinctly significant.

C. J. WEST.

**Differences in the action of drugs on different parts of the bowel.** WALTER C. ALVAREZ. Univ. Cal. Med. School. *J. Pharmacol.* 12, 171-91 (1918); cf. *C. A.* 12, 2384.—Results are given of tests of 76 substances. A list of convenient dosages is appended.

C. J. WEST.

**Anthelmintics: their efficiency as tested on earthworms.** TORALD SOLLMANN. Western Reserve Univ. *J. Pharmacol.* 12, 129-70 (1918).—All clinical anthelmintics are markedly toxic to earthworms. This simple test may therefore be used for detg. whether a given substance has any anthelmintic properties, and also to det. the relative activity of different samples of a given drug. It could not be used to compare the clinical value of different anthelmintics, since this often involves factors other than simple vermucidal efficiency, such as absorption, local and general toxicity, etc. *Aspidium*, *chenopodium*, *pelletierine*, *thymol*,  $\beta$ -*naphthol*, and  $\text{CHCl}_3$  are highly effective. So is *santonin* in the presence of an appropriate solvent (bile salts and  $\text{NaHCO}_3$ ). Somewhat less effective, but still quite toxic are *kamala*, *kousso* and *granatum*. *Spigelia* is rather feeble. Fresh (germinable) pumpkin and squash seeds are highly efficient, the active principle being sol. in water and destroyed by boiling. In view of their cheapness, availability and presumably low toxicity to men, renewed clinical interest in these is indicated. Spices and "sharp" substances, including

mustard, pepper, onion and cantharidine, are toxic. Their use in the preparatory treatment is therefore well justified (except of course cantharidine). Indeed, pepper potentiates or synergizes the effects of the more active anthelmintics. Mixtures of the active anthelmintics give simple summation of efficiency. This may be useful for decreasing their toxic effects on the hosts. Oleoresin of *aspidium* appears to be stable, although the dry rhizome deteriorates. Different samples agree fairly well in activity. Different samples of pelletierine tannate are also of fairly uniform activity. The pelletierine tanret is a secret prepn. without any advantages. Most substances that are toxic to earthworms produce a primary irritation or agitation that results in the withdrawal of the worm from the neighborhood of the poison. By virtue of this effect, anthelmintics doubtless often expel the parasite when the concn. does not rise sufficiently high to kill the worm.

C. J. WEST.

**Primary depression and secondary rise in blood pressure caused by epinephrine.** HUGH MCGUIGAN AND EMRY G. HYATT. Univ. of Ill. *J. Pharmacol.* 12, 59-69(1918).—In most dogs, especially mature animals in good health, the intravenous administration of adequate doses of epinephrine (0.5 to 1 cc. of 1:10,000), after a quick rise in the blood pressure, is followed by a rapid fall and a secondary rise. The secondary rise is apparently due to a central action of the epinephrine acting through the sympathetic ganglions. The basis for this belief is that the removal of the head or pithing of the brain prevents the occurrence of the phenomenon. Also, paralysis of the ganglia with nicotine prevents it. It occurs after the sectioning of the vagi and the administration of atropine or pilocarpine. The vagus apparently is not involved in the mechanism. Artificial intracranial pressure during the administration of epinephrine will cause similar changes in the blood pressure.

C. J. WEST.

**The relation between the chemical structure of the opium alkaloids and their physiological action on smooth muscle with a pharmacological and therapeutic study of some benzyl esters. I. The relation of the chemical structure of the opium alkaloids to their action on smooth muscle.** DAVID I. MACHT. Johns Hopkins Univ. *J. Pharmacol.* 11, 389-417(1918).—In respect to their action on all kinds of smooth muscle, the opium alkaloids can be divided into 2 classes: the pyridine-phenanthrene group, of which morphine is the principal member, and the benzyl-isoquinoline group, of which papaverine is the principal member. Morphine and its related alkaloids tend to increase the contractions and raise the tonus of smooth muscle, while papaverine and its related alkaloids have the reverse effect. The stimulating or pressor effect of morphine seems to reside in the pyridine or piperidine portion of its molecule, while the inhibitory or depressor effect of papaverine seems to reside in the benzyl portion of its mol. **II. A pharmacological and therapeutic study of some benzyl esters.** *Ibid* 419-46.—A pharmacological study of benzyl benzoate and benzyl acetate shows that these esters produce the same effects on smooth muscle tissue as the opium alkaloid papaverine. These esters are easily metabolized by the body and are comparatively non-toxic. The low toxicity and the papaverine-like action has led to their clinical employment in conditions of excessive peristalsis or spasm of smooth muscle viscera, with successful results. The minimum lethal dose of benzyl benzoate for dogs after intravenous injections in the form of emulsion is about 1.5 cc. per kg. By subcutaneous injection in cats, the dose is from 1 to 1.5 cc. per kg. In rabbits 1 cc. can be injected subcutaneously with impunity. For rabbits the dose is about 2 cc. In guinea pigs the dose is about 1 cc. The toxicity of the acetate is slightly higher, due to its quicker absorption.

C. J. WEST.

**Studies on the biochemistry and chemotherapy of tuberculosis. XVI. The pharmacology and toxicology of copper salts of amino acids.** HARRY L. HUBER. Univ. Chicago. *J. Pharmacol.* 11, 303-29(1918).—Cu, whether in the form of the sulfate, leucinate,

glycinate or glutamate, shows no variations in action when introduced into the conjunctiva of rabbits. The lower dilns., 1%, produce hyperemia and lachrymation to the same degree, while the higher dilns. are inactive. It also shows very little, if any, variation in ability to produce acute intoxication when introduced in dil. soln., subcutaneously. The diln. is important as the local injury produced by higher concns. interferes with absorption. The toxic subcutaneous dose was found to be between 4 and 6 mg. per kg. for guinea pigs. When introduced intracutaneously, the lower dilns. cause necrosis and induration and the higher dilns. cause little or no change. The histological change with the same diln. is the same for all salts. The salts likewise show no variation in action when introduced in small gradually increasing doses, 0.5 to 1 mg. Cu per kg., for a long period of time, 105 days, either subcutaneously or intramuscularly. This dosage of Cu seems to produce no gross or microscopic changes in the organs examd. All the salts mentioned above have the same ability to dialyze through celloidinf sacs when either water or horse serum is used both inside and outside the sac. The rate of dialysis is somewhat faster with distd. water than with horse serum. No variation was noted when the salts were introduced by feeding in small gradually increasing doses to 10 mg. per kg. per day for 72 days. The results were very similar to those obtained from subcutaneous or intramuscular administration. Thus the work seems to show that the 3 Cu amino acid salts examd. produce exactly the same physiol. effects as a simple inorg. salt,  $\text{CuSO}_4$ . XVII. Distribution of gold in animal tissues. LYDIA M. DEWITT, SIDNEY M. CALDWELL AND GLADYS LEAVELL. O. S. A. Sprague Memorial Inst. and Univ. of Chicago. *Ibid* 357-77.—Gold differs somewhat from other metals in its distribution in the animal body. It seems to select the spleen by preference since the amt. per g. wt. or the gold concn. in the spleen is in most cases much greater than in the liver. Either the kidney or the liver may come 2nd in gold concn. About 0.5 of the gold administered has been recovered from the urine and feces within 7 days after a single injection and in 2 months during which weekly injections were given; more is excreted through the urine than through the feces, at least in the earlier part of the treatment. Gold salts are readily absorbed after subcutaneous injection. They are quickly taken up from the blood after intercardiac injection and usually no more than a trace of gold is found in the circulating blood 24 hours after the injection. Two to 4 hours after the last injection no gold was found in the clear serum but a considerable amt. was recovered from the blood cells. No gold was found in the brain. The amt. of gold administered, the duration of treatment and the time since the last dose seem to exert no const. or consistent influence on either the total or proportional gold content of the animal organs. C. J. WEST.

The effect of intravenous injections of some sodium salts with special reference to the supposed toxicity of sodium phosphate. ISIDOR GREENWALD. Roosevelt Hospital, N. Y. *J. Pharmacol.* 11, 281-301 (1918).—The symptoms observed after intravenous injection of neutral solns. of Na salts ( $\text{NaCl}$ ,  $\text{Na}_2\text{SO}_4$ ,  $\text{Na}_2\text{HPO}_4$ ) depend upon the changes in the volume of circulating fluid, changes in osmotic pressure, changes in reaction, due to selective retention of the cation, disturbances of the relation between Na and K, Ca and possibly other ions in the blood and other tissues, the nature of the anion, but probably only through the effect in detg. the permeability of the cells to the Na. There is no evidence of a direct toxic action of the  $\text{PO}_4$  ion. C. J. WEST.

Poisoning with methyl alcohol. J. POHL. *Arch. exp. Path. Pharm.* 83, 204-20; *Physiol. Abstracts* 3, 275.—Although MeOH produces cerebral effects, no organ contains so little of the alc. as the brain. It is more sol. in  $\text{H}_2\text{O}$  than in fats, and the lipid solubilities are stated not to be of any moment. A variety of medicaments, among which Ringer soln., charcoal and yeast (subcutaneously), NaI, adrenaline and alkalies

figure, are recommended for detoxication and it is claimed that such a treatment rests on a rational basis.

C. J. WEST.

**Effect of lactic acid on the respiratory center.** SEYMORE J. COHEN. Univ. Ill. *J. Pharmacol.* 11, 221-8(1918).—Lactic acid, when injected intravenously in moderate doses, about 0.5 cc. *N* acid per kg. body wt., produces marked increase in respiratory rhythm, both in rate and amplitude. This is not specific but may be produced by practically any acid. The mechanism of this hyperpnea probably involves 3 factors. The acid may liberate  $\text{CO}_2$  from the blood carbonates and the excess  $\text{CO}_2$  may play some part in the excessive movement; the acid may act as a direct respiratory stimulant; probably most important, the acid sensitizes the respiratory center.

C. J. WEST.

**An experimental study of the venom of the Manchurian scorpion.** SEIKO KUBOTA. Japanese Medical School, Mukden. *J. Pharmacol.* 11, 379-88(1918).—An ext. of the dried, expressed juice of the venom glands of the scorpion injected into a frog produces the same symptoms as those following a bite by the living animal (primary spasm and twitching of the muscles and increased reflex excitability, followed by paralysis). These are of peripheral origin due to the direct action of the poison on the motor nerve endings; when the excized muscle is immersed in the toxic ext. the motor nerve endings lose their excitability. The concd. exts. of the venom glands produce an irritation of sensory nerve endings. The toxic ext. has no definite action on the nerve trunks or on striated muscle itself. The minimum fatal dose for frogs varied from 0.05 to 0.1 mg. per g. wt.

C. J. WEST.

**Cutaneous irritation by mustard oil as influenced by various solvents.** T. SOLL-MANN. Western Reserve Univ. *J. Pharmacol.* 11, 229-30(1918).—Olive oil and other good solvents for mustard oil hinder its penetration into the skin. The greatest irritation is obtained by aq. suspensions, for instance, in mucilage.

C. J. WEST.

**The physical-chemical theory of narcosis.** J. VESZI. *Archiv ges. Physiol.* 170, 312-36; *Physiol. Abstracts* 3, 269.—The exptl. part consists in the demonstration that bacteria which are obligative anaerobes can be narcotized and then lose their motility. It is therefore clear that narcosis is not essentially due to a depression of oxidative changes alone. The remainder of the paper is theoretical. The velocity of reaction, or of the phases of a progressive reaction, depends on the surface tension at the interphase surfaces and narcosis depends on a reversible lowering of this surface tension. A quant. expression (of which the Meyer and Overton theory is the qual. expression) can be deduced from the adsorption formula and the Henry Dalton law, and is applicable to a variety of conditions.

C. J. WEST.

**Antiseptic power of Vincent's boro-hypochlorite mixture.** BAZIN. *Compt. rend. soc. biol.* 81, 122-4(1918).—The antiseptic power of Vincent's boro-hypochlorite mixt. was compared with that of  $\text{CHI}_3$  and tincture of I. A sample of soil containing 9-11 millions of bacteria per g. was used for inoculating the media employed; this soil contained *B. coli*, *B. proteus vulgaris*, *B. subtilis*, a bacillus of the *B. perfringens* group and, in addition, many unidentified species. Pathogenic species were present, as was shown by the rapidly ensuing death of guinea pigs with antiseptically produced muscular wounds in which small amts. of the soil had been introduced; the septic vibrio was subsequently isolated from the wounds. The following min. amts. of antiseptics were required in order to prevent bacterial development in bouillon containing 10 cc. of soil per l.:  $\text{CHI}_3$  25 g., tincture of I 10 g., Vincent mixt. 3 g. The following min. amts. per l. of bouillon were required in order to destroy within 24 hrs. the bacteria present in 1 g. of soil: tincture of I 20 g., Vincent mixt. 8 g.;  $\text{CHI}_3$ , even in large amt., failed to produce complete sterilization. The relative toxicity of these antiseptics, when introduced into the peritoneal cavity of guinea pigs, was next

studied. Painting of the cavity with tincture of I caused an intense reaction and death;  $\text{CHI}_3$  in large amt. had the same effect. The Vincent mixt., even in large amt., caused only a mild reaction without death. The action of tincture of I was practically the same as that of the Vincent mixt. in the case of cutaneous and superficial wounds infected with the soil; the utility of  $\text{CHI}_3$  was distinctly less. Vincent's mixt. was greatly superior to the other antiseptics in the case of muscular wounds; it was very well tolerated, while tincture of I was strongly caustic for muscular tissue. Vincent mixt. was much superior to tincture of I in the case of osseous wounds.

H. S. PAINE.

**Internal secretions and enzymes, their inter-relation and inter-dependence, their value and application in modern therapy.** JOHN J. McNULTY. *J. Am. Inst. Homeopathy* 11, 531-40 (1918).—A review, with special stress on the therapeutic value of polyglandular therapy.

JOSEPH S. HEPBURN.

---

## 12. FOODS.

---

W. D. BIGELOW AND F. F. FITZGERALD.

Use of saccharin as a sugar substitute (HENSEL) 17.

**Food preparations.** H. H. SENIOR. *Brit.* 118,874, Aug. 28, 1917. Whey from cheese-making is heated to about  $190^{\circ}\text{F}$ . to ppt. coagulable constituents, which are sep'd. by settling and draining and are dried and powdered. Cf. 25,127, 1909.

**Bread and biscuits; food preparations.** R. GRAHAM. *Brit.* 116,272, May 1, 1918. Bread, biscuits, rusks, crackers, breakfast food prepn's., and the like, in which all the ingredients of the grain are used and rendered assimilable, are prepd. from any whole grain, etc., by (1st) malting some grain, (2nd) treating the bran and middlings of another quantity and quality of grain with the malted grain, (3d) mixing the latter product with the flour from which the bran, etc., was sep'd. and which has been acted upon by yeast, and (4th) baking. In carrying out this process, soft wheat, that is grain high in starch but low in gluten constituents, is malted. This may be done by any usual process, but is preferably performed by steeping at about  $60-70^{\circ}\text{F}$ . and then slowly germinating till the acrospire is about two-thirds of the length of the grain. This process takes from 10 to 17 days. The malted grain is then treated in a kiln with dry air heated to about  $160-190^{\circ}\text{F}$ , and is then stored in air-tight bins, etc., for from 6 weeks to 3 mos. to mellow or ripen, after which it is ground. The main supply of grain, which should be a strong kind, high in gluten constituents, is milled, and the middlings and bran therefrom are combined and mixed with a quantity of the malted product and with  $\text{H}_2\text{O}$  to form a soft paste. The mixt. is then heated to about  $100-150^{\circ}\text{F}$ . for from 12 to 36 hrs. with occasional stirring. The product obtained, after drying for about 12 hrs. at  $130-150^{\circ}\text{F}$ ., may be used as a finished breakfast food product. The superior white, spring clear, and low grade milling fractions of the flour from which the bran, etc., have been removed, are now acted upon, preferably sep., by yeast at about  $81^{\circ}\text{F}$ ., to form sponges, and the sponges obtained are mixed together and with the soft paste, previously obtained, salt and  $\text{H}_2\text{O}$  to form a dough. When ripe, the dough is cut up, proved and baked in a slow oven at about  $330^{\circ}\text{F}$ ., decreasing to about  $290^{\circ}\text{F}$ . for from 3.5 to 4 hr. to form the desired bread. The invention is stated to be applicable to treating all kinds of cereals, beans, peas, potatoes, cassava, turnips, carrots, etc.

**Egg preparations.** E. S. SPENCER and F. F. KEMP. *Brit.* 119,007, Apr. 17, 1918. Whole eggs and the yolks of eggs sep'd. from the whites are dried to powder and mixed in the proportion of 3 parts by wt. of the whole eggs to 2 parts of the yolks.

The resulting compd. is stated to contain 42.6% protein, 49% fat, 3.4% ash, and 5% H<sub>2</sub>O. For use, the powder is mixed with H<sub>2</sub>O in the proportion of 65 parts H<sub>2</sub>O to 35 of powder.

**Butter substitutes.** J. J. A. TALBOT. Brit. 118,215, Dec. 13, 1917. A process for prepg. a butter substitute on a domestic scale consists in utilizing waste fats, and meat or bones having adherent fatty matter, such material being chopped up, slowly melted or simmered down at a temp. of about 42°, clarified by the addition of salt, and strained. The clarified fat is poured into a mixing receptacle, milk and a binding or saponifying agent such as white of egg or dried blood, together with coloring matter if desired, are added, and the mixt. is churned until it assumes a pasty condition of the consistence of butter. A suitable app. is specified.

**Evaporated vegetable products.** PACIFIC EVAPORATOR CO. Brit. 118,466, Sept. 5, 1917. In the evapn. of food products of a vegetable nature, and particularly potatoes, the sliced potatoes or the like, placed on trays, are subjected to a steaming process, dry steam being employed. The steaming is continued only for a very short time, so that no breaking down of the cells occurs. The steamed potatoes are then dried in an evaporator kept below 156° F., atm. humid air being employed to obtain a uniform drying. Previous to steaming, the unsliced potatoes may be subjected for a short time to a 3% soln. of NaCl and the sliced potatoes to a similar soln., to prevent discoloration.

**Milling wheat.** J. S. REMINGTON. Brit. 118,431, July 28, 1917. Wheat is treated, preparatory to milling, by washing with a soln. of Na or K carbonate. The soln. is removed from the grain in a whizzer and the grain is dried by treatment with cold, preferably artificially cooled, air. The small amt. of carbonate retained by the grain affects the gluten, and improves the baking qualities of the flour obtained from the grain

**Soy-bean milk.** W. J. MELHUISE. Brit. 118,535, Dec. 10, 1917. In prepg. artificial milk from soy bean as described in 24,572, 1913 (C. A. 9, 1205), the beans are soaked in H<sub>2</sub>O before being ground. The residue, after treatment to obtain an albuminous ext. and sepn. in a filter press, is submitted to high pressure for about 2 days to sep. oil and to obtain a meal not too rich in oil, which may be used as a food for cattle, poultry, etc., or as an addition to flour for bread-making, or mixed with bread crumbs, flavored with honey, meat ext., etc., and baked to form a breakfast food. The albuminous ext. is prepd. by mixing the meal and H<sub>2</sub>O in a steam-jacketed pan fitted with cone-shaped cup stirrers open at both ends. The same pan, exhausted of air, is used subsequently to mix the ext. with sugar and fat, sesame or arachid oil being used to prep. milk for ordinary purposes, and coconut oil to prep. a milk for margarine making. The emulsified mixt. is treated with a culture and pasteurized. Acids such as butyric or citric acid, or substances such as CaO, MgO, or NaHCO<sub>3</sub>, may be added. The oil contained in the albuminous ext. is sepd. by centrifugal action and the slime obtained may be used as a soap base. Cf. 30,275, 1910 (C. A. 6, 1646), 9,626, 1915 (C. A. 11, 78), and 13,903, 1915 (C. A. 11, 506).

**Apparatus for sterilizing milk.** F. H. ROGERS. U. S. 1,280,851, Oct. 8.

#### 14. WATER, SEWAGE AND SANITATION.

EDWARD BARTOW AND W. F. MONFORT.

**Chemical control of water softeners.** L. F. CLARK. *Chem. Met. Eng.* 19, 674-7 (1918).—A discussion of the reactions involved in the lime-sod aprocess, and the derivation of a practical and simple field routine analysis. The methods outlined are designed for application by untrained men, and have the advantages and disadvantages incident to such conditions.

M. C. PERRY.

**Mobile chlorine water-purification plant.** R. K. TOMLIN, JR. *Chem. Met. Eng.* 19, 678-80(1918); see C. A. 12, 2639. M. C. PERRY.

**Slow sand and multiple filtration.** WALTER CLEMENCE. *Engineer; Eng. Contr.* 50, 123(1918).—Multiple filtration ending with slow sand filters is suggested as a possible substitute for present practice. L. P.

**Chlorination of Chicago's water supply.** J. ERICSON. *Am. J. Pub. Health* 8, 772-5(1918).—The bacteriol. tests made on untreated water during 1916 showed *B. coli* present in 1 cc. in 18 samples out of 1000 examd.; during the first 9 months of 1917 the treated water showed *B. coli* present in less than 1 per 1000. During the first 9 months following the complete chlorination of Chicago's water supply the death-rate from typhoid fever was reduced 71.44%. There is, therefore, a strong indication that the use of Cl reduced the death-rate due to typhoid fever more than 70%.

M. C. PERRY.

**Excess lime treatment system for Aberdeen (Scotland) waterworks.** A. C. HOUSTON. *Engineer; Eng. Contr.* 50, 100(1918).—The author recommends treatment of Deon water with from 1 to 2 parts per 100,000 of CaO, storage for 7 days, artificial carbonation if required, and sand filtration. LANGDON PEARSE.

**Microbiological investigations of some Japanese water systems.** H. HATTORI. *J. Coll. Sci. Imp. Univ. Tokyo* 40, 7 pp.(1917).—A study of the action of slow sand filters in purification of surface waters. The species of bacteria and other life forms occurring in the working layer in Japanese filters together with the character of raw waters permit a higher rate of filtration without sacrifice of efficiency. M. C. P.

**Analysis and quality of water.** *Munic. J.* 45, 26-8(1918).—A tabulation of analytical data from a number of cities. L. P.

**Hypochlorites in drinking water.** A. R. LING. *Analyst* 43, 347-8(1918).—Ammonia and amino compds. are converted into chloramine and chloramino derivs. when treated with hypochlorite. The Cl in chloramines liberates I from KI; hence, to ascertain whether a water containing much org. matter has been treated with hypochlorite treat as follows: Place 50 cc. of the water and 50 cc. of distd. water in 2 cylinders and add to each 1 cc.  $N H_2SO_4 + 0.1$  g. KI. The water which has been treated with hypochlorite will liberate I giving a brown coloration; the distd. water will remain colorless. Nitrites will liberate I but these should have been oxidized by the hypochlorite. M. C. PERRY.

**Substances dissolved in rain and snow.** V. C. SHIPPEE AND L. FORDYCE. *Chem. News* 117, 322-3(1918).—Forty-one pptns. during the period from Sept. 29, 1917, to June 1, 1918, were analyzed. The total rain and snow during that period was the equiv. of 17.9 in. of rain. An attempt was made to establish a relationship between the time elapsing between 2 pptns. and the amt. of various substances found in the water; no definite conclusions were reached. Except in the early fall, the highest amts. of sulfates were obtained during the winter. Phosphates were found, but repeated tests failed to detect the presence of  $CO_2$ . M. C. PERRY.

**Development of sewage treatment.** KENNETH ALLEN. *Munic. Eng.* 55, 244-9(1918).—A review of the problem in detail, touching on recent developments in tanks, screens, activated sludge, acid recovery of grease, etc. L. P.

**Worcester (England) experiments with activated sludge process.** *Surveyor; Eng. Contr.* 50, 122-3(1918).—An existing tank 86 by 78 by 18 ft. deep was baffled into 36 bays, each 21 x 8 ft. wide, of which 20 are aeration and 8 are settling tanks. Perforated pipes are used with holes 12 in. apart, over which are placed porous tiles forming the bottom of valleys. Settling tanks have 60 deg. bottoms with 6 in. air lift. Sludge has 95% water. The aeration period is 6 hr. with flow rate of 1 mill. gal. per 24 hr.,

plus 20% sludge, settling period 1 hr. 40 min. 750,000 gal. per 24 hrs. is actually treated. Analyses are given. L. P.

**Pressure of sewage sludge.** F. A. DALLYN. *Trans. Am. Soc. Mun. Impmts.; Can. Engr.* 35, 69-70(1918).—The presence of grease may interfere with filter-pressing. Acidification, as at Bradford, Eng., and heat in press helps grease recovery. A possible use of sewage grease may be in textile soaps. The author is hopeful as to eventual recovery of fertilizer. L. P.

**Electrochemical sewage treating process at Decatur, Ill., in 1916.** W. S. SHIELDS. *Munic. Eng.* 54, 68-73(1918).—The city of 50,000 population discharged sewage with starch waste into a flashy river. An exptl. electrolytic plant of 1 mil. gal. capacity per 24 hr. was built to demonstrate a process whereby sewage mixed with CaO flows between iron electrodes to settling tanks. The estd. annual cost of the process including interest and depreciation lies between that of sprinkling filters and activated sludge. Sludge utilization was not effected. Analytical data with bacterial results are given. LANGDON PEARSE.

**Methods of sampling of sewage and other liquids.** G. B. KERSEAW. *Surveyor; Eng. Contr.* 50, 111.—Detailed directions for making 24-hr. composite, proportional to flow, from hourly samples. L. P.

**Camp sanitation.** C. B. HARTFREE. *Surveyor; Eng. Contr.* 50, 134.—Suggestions are given for equipment for ablutions and for water purification. The employment of canvas reservoirs, of colored flags to designate the use of water, the use of 6 gr.  $\text{Al}_2(\text{SO}_4)_3$  per gal. and sedimentation for clarification, spent tea leaves for color removal, and  $\text{KMnO}_4$  for oxidation are recommended. L. P.

**Suggested modifications of the standard method for the study of the dust content of the air.** H. F. SMYTH. *Am. J. Public Health* 8, 769-71(1918).—The standard method calls for 5 classes, based on the area of the dust particles as compared with the standard unit, or the smallest ruled square in the Sedgwick-Rafter eye-piece: (1) 0.04 sq. mm., (2) 0.01, (3) 0.0004, (4) 0.00014 sq. mm., (5) particles too small to count (presence indicated by plus sign). S. suggests that the 2 larger classes be eliminated and that class 5 be divided into 1 or 2 divisions. He used the following classes: 0.04, 0.01, 0.004, and 0.001 mm., and suggests that 0.04, 0.004, 0.01 and 0.001 mm. be used in the future. He also suggests the reporting of solids per 100 ft. rather than per m. l. and the detn. of the mineral and org. content of the air. M. C. PERRY.

**Softening water.** E. EDSEY and S. TUCKER, and MINERALS SEPARATION, LTD. *Brit.* 118,668, Sept. 3, 1917. Ca and Mg salts or other metallic impurities are pptd. by ordinary reagents, the ppt. being formed into a froth with the aid of a suitable frothing agent, such as oleic acid, soap, eucalyptus oil, or turpentine, and removed by flotation, the process being analogous to the processes of ore treatment described in 7,803, 1905, 2,359, 1909, 21,857, 1910 (*C. A.* 6, 1426) and 105,627.  $\text{Na}_2\text{PO}_4$  or a mixt. of  $\text{Na}_2\text{HPO}_4$  and NaOH is preferred as precipitant for Ca and Mg salts, but other known precipitants may be used. Sol. salts of Cu or Zn may be pptd. with CaO or NaOH and the ppt. may be formed into a froth with the aid of turpentine.

## 15. SOILS, FERTILIZERS AND AGRICULTURAL POISONS.

J. J. SKINNER.

**The reactions of the soils supporting the growth of certain native orchids.** EDGAR T. WHERRY. *J. Wash. Acad. Sci.* 8, 589-98(1918).—The majority of the native orchids grow in peats which are acid in reaction, but some are reported to occur in

limestone regions, where the soils are likely to be alk. Examn. of certain of these occurrences showed that the soils in these regions may be acid also, the calcareous rock being buried beneath vegetable matter or sandstone drift. It seems evident that conclusions as to the requirement of alk. or acid conditions by a given species can be depended upon only when based on actual investigation of the soils in which they grow. A method for measuring acidity in the field has therefore been worked out, based on the effect of varying H-ion concn. on different indicators. The soil is shaken up with water and allowed to settle, the effect of turbidity being overcome by viewing the pure indicator solution through a layer of soil extract, while comparing it with an equal volume of indicator solution to which soil extract has been added. The indicators used, starting with the most acid, are: bromophenol blue, methyl red, bromocresol purple, phenol red and phenolphthalein. About 200 soil samples collected as close to the roots of the plants as possible were examd. It was found that a few species do actually grow in the waters of calcareous swamps where the alkalinity is about 10, according to the scale proposed: the neutral point is made 1, and acidity or alkalinity described by direct numerical intensities instead of exponents, as is usually done. Other species grow on hummocks of moss in the same swamps, where the acidity is found to increase upward, often reaching an acidity of 300 ( $P_H = 4.5$ ) at the top. Still others grow in woods, in weakly acid soils, the upper limit for many of them being acidity 100 ( $P_H = 5.0$ ), for an additional number 300 ( $P_H = 4.5$ ). Finally in peat overlying clay around the margins of swamps the acidity was found to reach, for one species, the high value of 3000 ( $P_H = 3.5$ ). The reaction appears to be more important than moisture content in detg. where a given species will grow.

E. T. W.

**Recent investigations of soil aeration. I. With special reference to agriculture.**

ALBERT HOWARD. *Agr. J. India* 13, 416-29(1918).—A lecture in which the relation of soil aeration to productivity is discussed. The soils permitting a free exchange of air produce best crops. The harmfulness of excessive irrigation is said to be due to the prevention of soil aeration. **II. With special reference to forestry.** R. S. HOLE. *Ibid* 430-40.—Where soil ventilation was interfered with in pot expts. Sal seedlings grew and developed poorly. The seedlings grew more rapidly in well-aerated soils than in those receiving no aeration. This is attributed to a lack of O and an excess of  $CO_2$ . The water expts. show that when the concn. of gas reaches roughly 500 mg. per liter the root tips and rootlets of Sal seedlings are blackened and killed and the production of new roots is inhibited.

J. J. SKINNER.

**Chemical analysis of soils from the Concepción plantation (Cruz Alta, Argentina).**

IVAN R. FONTANA. *Univ. Tucumán inform. depart. investig. industr.* 1917, 27-33.—F. reports an analysis of a siliceous, slightly calcareous soil with no humus and a siliceous, very slightly calcareous subsoil without humus. He discusses the legitimate function of the soil analyst in his relation to agriculture and the conclusions and practical value of these conclusions which may be deduced from an analysis. In the present instance comparison of the analyses of soil and subsoil gave a negative answer to the question whether the land should be cultivated more deeply.

H. S. PAINE.

**A method for the counting of certain protozoa in the soil.** ARAO ITANO AND GEORGE B. RAY. *Soil Science* 5, 303-10(1918).—Direct microscopic counts are made conveniently with the aid of the vital stain phenolsulfonaphthalein of the organisms in films of the soil suspension thickened with gelatin. Probable error calcs. were made.

L. J. GILLESPIE.

**Cultivation of alkali soils in the northern provinces (of Argentina).** ENRIQUE F. SCHULTZ. *Univ. Tucumán inform. depart. investig. industr.* 1917, 45-51.—Salts of alkali metals caused more damage to crops at the end than at the beginning of the growing season, this being due to gradual accumulation of these salts at the surface

of the soil owing to capillary ascension of their aq. solns. and evapn. of the same. The harmful effect of these salts is physiological rather than purely chem.; the crust of salts formed around the stems and trunks of the plants has great affinity for  $H_2O$  and injures the plants by a process of plasmolysis. The custom of growing rice on these soils for a no. of yrs. is effective, on account of the frequent application of  $H_2O$ , in leaching out a great proportion of the alk. salts but leaves the land in bad physical condition and tends to prevent free access of O to the soil. S. makes the following suggestions for cultivating alk. soils: (1) growing of crops which show greater resistance to alk. salts; (2) installations of an adequate system of drainage; (3) moderate irrigation in combination with rational cultivation; (4) retention of moisture in the soil (thus reducing the capillary ascension of alk. salts in soln.) by means of frequent cultivation and also by using a secondary growth of certain plants (preferably legumes) to protect the terrain from excessive effects of sun and wind; (5) by applying humus (green manures, etc.) so as to reduce evapn. of moisture; (6) application of gypsum to soil which contains  $Na_2CO_3$ , thus causing gradual productions of  $Na_2SO_4$  and  $CaCO_3$ ; (7) in clearing a virgin terrain plants which have become more or less habituated to alk. salts should be removed to another locality before being burned, in order that the salts present in the ash may not be again introduced into the soil.

H. S. PAINE.

**The influence of aeration upon the yields on bog soils.** BR. TACKER. *Mitt. des Vereins zur Förderung der Moorkultur im Deutschem. Reiche* 35, 2(1917); *Biedermanns Zentr.* 47, 95(1918).—It was found "that under the exptl. conditions chosen no distinctly favorable influence of increased aeration appeared."

ALBERT R. MERZ.

**Contribution to the agricultural study of iron.** A. MONNIER AND L. KUCZYNSKI. *Arch. sci. phys. nat.* 43, 66-8(1918).—In order to throw some light upon the different results obtained by previous investigators in studying the effect of iron when applied to soils, M. and K. planned lab. expts. to det. the soly. of Fe present in the soil and to det. the changes which ferrous and ferric compds. undergo in contact with arable soil. A fallow soil containing 3.2% Fe and 6% Ca yielded small amts. of Fe when treated with dil. org. acids, though only traces to distd.  $H_2O$  and dil. soln. of alkali carbonates and bicarbonates. Certain siliceous soils, completely exhausted of Ca, containing an appreciable amt. of  $H_2O$ -sol. Fe, when planted with rose-colored hydrangea, yield a blue flower, but when  $CaCO_3$  or  $MgCO_3$  is added no additional amt. of  $H_2O$ -sol. Fe is obtained and a flower of normal color results. 0.001 N soln. of  $FeCl_2$  filtered through a layer of soil 20 cm. thick showed no Fe in the filtrate but large amts. of Ca and Cl; the upper layer of the soil retained the Fe, and assumed a dark brown color. The line of demarkation was very plain and it was noted that the thickness of the colored portion was greater for the soils poorer in Ca.  $FeSO_4$  reacted the same as  $FeCl_2$ . M. and K. conclude from these results that the Fe normally present in soils is insol. This explains the increase in yield from the addition of small amts. of Fe. Such favorable action does not result unless the fertilizer is placed within reach of the roots, as otherwise the surface layer removes it by rendering it insol. In attempting to substitute  $K_4Fe(CN)_6$  as a source of Fe, it was noted that the compd. was not rendered insol. but underwent a double decompn., only part of the K remaining in the soil, and the filtrate contained the balance of the salt as  $K_2Fe(CN)_6$ . According to M. and K. this reaction is due to adsorption, as the same phenomenon is observed in filtering the soln. through a layer of fine sand. Plot expts. with  $K_4Fe(CN)_6$  did not yield good results since even very dil. solns. were toxic.

R. B. DEEMER.

**Some experiments with U-cultures.** VOGEL. *Leipzig. Deutsch. landw. Presse* 44, 522(1917); *Biedermanns Zentr.* 47, 90-3(1918).—Pot and field expts. were conducted with oats. Either the soil or the seed was inoculated with "Universal" cultures, which were claimed to render N available to non-legumes by fixation of atm. N and by rendering

the N compds. of the soil sol. "Nitragin-Compost" ("a compost prepd. in a special way and containing much humus, fecal substances, lime salts, some N,  $P_2O_5$ , etc., and intensively permeated with quite a large quantity of U-cultures prepd. in concd. form for the purpose"), the N content of which was 0.402%, was simultaneously tested. Contrary to the observations published by A. Kühn (*Deutsch. landw. Presse* 44, 467-8 (1917)) only 8% of the tests showed any benefit by the inoculations. Fertilization with N without inoculation caused considerable increase of yield in the pot expts. but only a relatively small one in the field expt. ALBERT R. MERZ.

Some experiments with U-cultures. A. KÜHN. Berlin-Grunewald. *Deutsch. landw. Presse* 44, 529-30 (1917); *Biedermanns Zentr.* 47, 93-5 (1918).—A criticism of the work of Vogel (preceding abstract). ALBERT R. MERZ.

Manures in relation to vines. H. E. LAFFER. *Agr. Gaz. N. S. Wales* 29, Pt. 7, 491-6 (1918).—A general discussion of benefits to be derived from the use of nitrogenous fertilizers (both from green manures and mineral nitrates),  $K_2SO_4$  and KCl, phosphates, lime and gypsum on Australian soils in connection with vineyards. R. B. DEEMER.

Top-dressing lucerne with superphosphate. ANON. *Agr. Gaz. N. S. Wales* 29, Pt. 7, 468-9 (1918).—Applications of 200 lbs. per acre of phosphate give large returns on heavy, black soils of basaltic origin. Results indicate that no advantage is gained by the use of  $K_2SO_4$ . R. B. DEEMER.

Conversion of insoluble phosphate. A. M. JOHNSTON. *J. Chem. Met. Soc. S. Africa* 18, 140-1 (1917).—Saldanha Bay phosphates, analyzing 20.6%  $P_2O_5$  and 0.4% sol.  $P_2O_5$  were treated by a method almost identical with that used in producing Wolter phosphate (cf. "Fertilizers and Manure," A. D. Hall, p. 135) yielding a product containing 13.8%  $P_2O_5$  and 12.4% sol.  $P_2O_5$  in 2% citric acid. Fusion with  $CaCO_3$  alone for 1.5 hrs. at 1,100° was tried; it gave a product containing only 6.4% sol.  $P_2O_5$ . Many trials with the fluxes used in varying proportions resulted in the selection of a mixt. of 25 g. of the phosphate; 17.5 g.  $NaHSO_4$ , 11 g.  $CaCO_3$  and 1.5 g. of powdered coke to produce the product yielding the above figures. R. B. DEEMER.

Decomposition and preservation of liquid manure. F. BLANCK. *Landw. Vers. Sta.* 91, 253-69, 271-90, 309-43 (1918); *J. Soc. Chem. Ind.* 37, 522-A.—Treatment of the urine with  $H_2SO_4$  can fix, up to a certain limit, the  $NH_3$  formed when urine is added to soil. Formaldehyde preserves the urine, but interferes with plant growth and is not recommended. I. J. GILLESPIE.

Use of stable manure for improving soil. IVÁN R. FONTANA. Univ. Tucumán extens. agric., *Bull.* 14.—F. discusses, among other things, the chem. changes which occur during the fermentation of manure and means by which loss of N as  $NH_3$  may be prevented. He protests against the wasteful agricultural methods prevailing in Tucumán (Argentina) and urges the increased use and conservation of manure, silage, etc. H. S. PAINE.

Some of the principal insects affecting vegetables in Trinidad and Tobago. F. W. URICH. *Bull. Dept. Agr. Trinidad and Tobago* 17, Pt. 2, 77-87 (1918).—A description of the prepn. and use of the usual sprays and insecticides used in the treatment of such garden pests as are found in this locality. R. B. DEEMER.

---

Treatment of copper ores (insecticides) (Brit. pat. 116,181) 9.

---

Fertilizer containing calcium urea phosphates. C. BOSCH. U. S. 1,280,650, Oct. 8. Products for use as fertilizers, which probably contain complex calcium urea phosphates, are formed by grinding together urea and a superphosphate containing primary Ca phosphate as its chief ingredient. The mass, which at first becomes moist,

soon loses its moistness and assumes the condition of a dry powder which may readily be distributed over the soil. Gaseous  $\text{NH}_3$  may be used for treatment of the product as it assists in maintaining the dry pulverulent condition of the material during storage.  $\text{NH}_4$  carbamate also may be used. The urea may be employed in the form of nitrate if desired and the proportions of the reacting substances are so regulated that the final product will contain about 9-13% each of N and  $\text{P}_2\text{O}_5$ .

## 16. FERMENTED AND DISTILLED LIQUORS.

ROBERT WAHL.

Analytical composition and definition of vermouth wines. W. I. BARAGIOLA. *Schweis. Apoth. Ztg.* 56, 381-2 (1918); cf. *C. A.* 11, 1013.—A recent ruling by the Italian ministry (*Giorn. vinic. ital.* 44, 194-5 (1918)) defines the scope in the making of vermouth wine from various Italian white wines, especially Canelli muscat wine which produces the genuine Turin article. Addition of cane sugar and purest  $\text{EtOH}$ , as well as aromatic plant extracts and caramel, is permitted. The mixt. is allowed to age, is pasteurized at  $60^\circ$ , cooled to  $5^\circ$ , allowed to ripen, and when clear, it is bottled. Its chem. compn. varies as follows:  $\text{EtOH}$  13.5 to 17% by vol.; total acid as tartaric, 0.4 to 0.5%; volatile acid as  $\text{AcOH}$  0.04 to 0.15%; reducing substances 0.8 to 1.5%; glycerol 0.5 to 0.9%; ash 0.15 to 0.3%; alkalinity of ash 8.0 to 30.0 cc. per l. These standards permit proper classification of inferior com. vermouth wines. S. W.

Materials for making alcohol; yeast. E. C. BAYER and S. ORLAJENSEN. *Brit.* 119,030, Aug. 29, 1918. Seaweeds, including both zostera and algae, are used, after hydrolysis with acids or otherwise, for the production of alc. and yeast.

## 17. PHARMACEUTICAL CHEMISTRY.

W. O. EMBERY.

Peru and Tolu balsams. V. MACRI. *Boll. chim. farm.* 57, 102-3 (1918).—When a drop of an  $\text{AcOH}$  soln. of synthetic Peru balsam was added to a soln. of a drop concd.  $\text{H}_2\text{SO}_4$  in 15 cc. glacial  $\text{AcOH}$  there was produced a distinct bluish green zone which slowly turned a deep violet-red; natural Peru balsam remained unchanged. The coloration produced by synthetic Peru balsam was practically the same as that given by Tolu balsam and  $\text{PhCHO}$ . Two samples (A and B) of Tolu balsam with quite different organoleptic properties were tested by adding 1 cc. of a 2% soln. of the balsam in  $\text{AcOH}$  to 1 cc. of the above soln. of  $\text{H}_2\text{SO}_4$  in  $\text{AcOH}$ . The colors produced were: (A) brownish yellow; (B) intense brownish red. When 1 cc. of the balsam soln. was treated with 2 cc.  $\text{Ac}_2\text{O}$  and 1 drop of the  $\text{H}_2\text{SO}_4$ - $\text{AcOH}$  soln. the colors produced were: (A) pronounced blue turning to yellow, green and brown in succession; (B) intense violet-red. When 1 cc. of the balsam soln. was treated with 2 cc.  $\text{Ac}_2\text{O}$  and 1 cc. of the  $\text{H}_2\text{SO}_4$ - $\text{AcOH}$  soln. the colors produced were: (A) intense violet-red turning quickly to brownish yellow; (B) deep violet-red. No appreciable difference between the 2 samples was noted when dil.  $\text{H}_2\text{SO}_4$  and  $\text{HNO}_3$  were used. Sample B was bright red in color (A was somewhat yellowish) and was harder and more transparent and had a better scent than A. In detg. cinnamic aldehyde in Peru balsam according to the Italian pharmacopoeia M.'s experience indicates that it is best to add the  $\text{H}_2\text{O}$  first, then the  $\text{Et}_2\text{O}$  and finally the alk. soln.

H. S. PAINE.

Aluminum acetoborate. ANON. *Boll. chim. farm.* 57, 104 (1918).— $\text{H}_2\text{BO}$  is used in the following proportion for stabilizing  $\text{Al}(\text{AcO})_3$  solns.: 700 g.  $\text{Al}(\text{AcO})_3$ , 30 g.  $\text{H}_2\text{BO}_3$ , 1000 g.  $\text{H}_2\text{O}$ . This soln. may be used with or without diln. An emulsion

may be prepd. viz.: 3 g.  $\text{H}_2\text{BO}_3$ , 10 g.  $\text{Al}(\text{AcO})_3$ , 40 g. lime water, 50 g. liquid vaseline. These preps. are used for burns and cutaneous affections.

H. S. PAINÉ.

**Solutions of atoxyl with mercuric iodide.** LABAT. *Boll. chim. farm.* 57, 104(1918).—The following solns. are recommended for intramuscular injections: (1) 10 g. atoxyl, 0.5 g.  $\text{HgI}_2$ , 5 g.  $\text{NaI}$ , sufficient distd.  $\text{H}_2\text{O}$  to make 100 cc.; (2) 10 g. atoxyl, 0.2 g.  $\text{HgI}_2$ , 2 g.  $\text{NaI}$ , sufficient distd.  $\text{H}_2\text{O}$  to make 100 cc. The solns. are placed in yellow glass bottles and sterilized.

H. S. PAINÉ.

**Solubility of iodoform in glycerol.** P. CHIARIA. *Giorn. farm. chim.* 66, 94-6 (1917).—In view of recent use of  $\text{CHI}_3$ -glycerol preps. (e. g., 2 g.  $\text{CHI}_3$  and 20 g. glycerol for intrapleural injection in respiratory diseases and the lack of data on the soly. of  $\text{CHI}_3$  in glycerol C. has made detns. of the latter. Ninety-five % glycerol ("bidistillata purissima") of  $d_{15} 1.255$  ( $29.34^\circ \text{Bé.}$ ) and recrystd. comm.  $\text{CHI}_3$  were used. Definite wts. of glycerol and  $\text{CHI}_3$  were heated 2 hrs. under a reflux condenser; the soln. was rapidly filtered and cooled to  $15^\circ$  and a definite wt. was treated with alc.- $\text{Et}_2\text{O}$ , 10 cc. of a 0.1 N  $\text{AgNO}_3$  soln. and 1 drop of concd.  $\text{HNO}_3$  and heated 1 hr. under a reflux condenser, excess of  $\text{AgNO}_3$  being then detd. with  $\text{NH}_4\text{SCN}$ . The soly. was 0.123% at  $15^\circ$ . Soly. was not greatly increased at increased temp. nor by use of  $30.6^\circ \text{Bé.}$  or anhydrous glycerol. The prepn. mentioned above should be sterilized by heating 1 hr. at  $100^\circ$  before using.

H. S. PAINÉ.

**Determination of the strength of alcoholic camphor solutions without a polarimeter.** J. PINKHOFF. *Pharm. Weekblad* 55, 1386-7(1918).—By detg. the sp. gr. of various mixts. of  $\text{EtOH}$  and camphor, and the number of cc. of  $\text{H}_2\text{O}$  required to produce turbidity in such mixts., tables can be compiled from which the strength of a camphor soln. can be quickly found after making these simple detns. The method is illustrated with curves and a numerical table.

JULIAN F. SMITH.

**The loss of hypochlorite content in standing solutions.** I. M. KOLTHOFF. Utrecht. *Pharm. Weekblad* 55, 1318-24(1918).—Analyses were made to det. the effects of light and alkalinity on the keeping qualities of hypochlorite solns. for surgical work. In general, these solns. keep much better in the dark than in light. Moderately alk. solns. keep better than those nearly neutralized with  $\text{NaHCO}_3$  or  $\text{CO}_2$ . An excess of alkali tends to protect against the action of light. Such decompn. as occurs in alk. soln. is partly by chlorate formation and partly by the reaction:  $2\text{NaOCl} \longrightarrow 2\text{NaCl} + \text{O}_2$ . In solns. neutralized with  $\text{NaHCO}_3$  or  $\text{CO}_2$ , the loss is almost entirely from chlorate formation. A moderately alk. soln., kept 14 days in the dark, had lost 7.6% of the original  $\text{NaOCl}$  content; but no further loss occurred during 2 months of standing in the dark.

JULIAN F. SMITH.

**Structure of the seed coat of *Paullinia cupana* Kunth.** A. TSCHIRCH and FINN KOLLE. *Schweiz. Apoth. Ztg.* 56, 445-7(1918).—An illustrated botanical description.

S. WALDBOTT.

**Pyrethrum and its cultivation.** H. FÄSS. *Terre vaudoise, Schweiz. Apoth. Ztg.* 56, 429-31, 447-50(1918).—An account of the successful cultivation of pyrethrum, since 1912 in the Swiss canton of Vaud, from genuine imported seeds of *P. cinerariaefolium*. The yield from 304 sq. m. area in 1 expt. was 14.6 kg. of dried flowers, from which 92.4 kg. of a concd. soap-pyrethrum soln. was prepd. to combat the *Cochylis* worm of the vine. For this purpose, the soln. is dild. 1 in 10. A max. of 50 l. is required for spraying a vineyard area of 450 sq. m. An old formula for spraying requires 1.5 kg. pyrethrum powder and 2 kg. of black soap dissolved in 100 l. of  $\text{H}_2\text{O}$ .

S. WALDBOTT.

**Sabadilla seed.** A. TSCHIRCH. *Schweiz. Apoth. Ztg.* 56, 457-9(1918).—Anatomical study, illustrated, of the seed of *Veratrum album*, related to sabadilla seed (at present

inaccessible in fresh state) to show that raphide cells claimed to exist normally in the seed coat of the latter, are present only in immature seeds. They, as well as starch, are always absent in ripe seeds. S. WALDBOTT.

**Localization of the active glucosides in leaves of the genus digitalis.** H. BALJET. *Schweiz. Apoth. Ztg.* 56, 248-51, 262-3(1918). See C. A. 12, 1687. S. WALDBOTT.

**Colloidal medicines.** R. EDER. *Schweiz. Apoth. Ztg.* 56, 369-74, 393-8, 408-10, 417-20(1918).—An address, giving a survey of colloidal phenomena, with special application to pharmacy, in particular the modern colloidal Ag preps. and those of other metals, e. g., the Aurum potable of the alchemists. S. WALDBOTT.

**Cultivation of medicinal plants in Norway and Sweden.** ANDERSSSEN. *Norges Apoth. Tidsskrift* 1918, 169; RUSTUNG, *Ibid* 1918, 69; *Schweiz. Apoth. Ztg.* 56, 398-400 (1918).—A. gives an historical account, referring especially to Angelica root. R. reports on the recent cultivation, near Christiania, of henbane, belladonna, and stramonium, the latter especially thriving well. Alkaloidal contents in all 3 plants were higher than when growing wild. Other plants cultivated with success are valerian root, verbasicum, chamomile, peppermint and opium, the latter containing 12.44% morphine. The gradual and uniform drying of medicinal plants is important. S. WALDBOTT.

**The seeds of cinchonas cultivated in Java.** A. TSCHIRCH AND FINN KOLLE. *Schweiz. Apoth. Ztg.* 56 405-7 (1918).—Of the total 23 species cultivated in Java, the exact dimensions of the fruit and the seed wings and the description of the latter are tabulated. S. WALDBOTT.

**Examination of powdered drugs.** H. ZÖRNIG. *Schweiz. Apoth. Ztg.* 56, 201-5, 213-7, 229-36(1918).—An address, giving a survey of the procedure in microscopical examn. of powdered drugs by the systematic use of certain reagents and appliances for quant. detn. of adulterations. S. WALDBOTT.

**Table of the more important tests and properties of official fats and oils.** P. FLEISSIG. *Schweiz. Apoth. Ztg.* 56, 216-21(1918).—Tabulation of tests and properties of 14 official fats and oils. S. WALDBOTT.

**Substitute for acetum sabadillae.** P. FLEISSIG. *Schweiz. Apoth. Ztg.* 56, 251 (1918).—Dissolve veratrine 5.0 g. in 40% com. AcOH 750.0 g., add H<sub>2</sub>O to make 5 l., and tincture of burned sugar 4.0 g. S. WALDBOTT.

**Can medicinal rhubarb and licorice root be cultivated in Switzerland?** A. TSCHIRCH. *Schweiz. Apoth. Ztg.* 56, 257-61(1918).—Medicinal rhubarb, derived chiefly from the northern plant *Rheum tanguticum* Tsch. growing in High Tibet, partly also from the southern *Rh. officinale* Baillon, is a mountain plant which could be cultivated with success in Swiss mountain woods at 2000 or 3000 m. altitude. A detailed account is given, based on Tafel's report from Tibet. Licorice root, on the other hand, thrives well in any soil, provided there is abundant moisture. This condition is fulfilled in the flood plains and deltas of rivers. The northern end of Lago Maggiore at Locarno would be an ideal place for the successful cultivation of this root. S. W.

**New remedies.** ANON. *J. pharm. chim.* 18, 139-40, 177-80, 208-12(1918).—*Acetozone* is a mixt. of equal parts of AcOOBz and an inert absorbent powder. In contact with H<sub>2</sub>O, it hydrolyzes, yielding peroxides having oxidizing and germicidal properties. It is sol. in 33 parts of oil, the soln. being used in inhalations; it is also sol. in Et<sub>2</sub>O, CHCl<sub>3</sub>, CCl<sub>4</sub> and petroleum oils. It is used as an antiseptic in ophthalmology and affections of the mouth, nose and throat. *Afridol*, the "Na salt of hydroxymercuric toluic acid" is used in the form of an antiseptic soap in parasitic skin diseases. It is not easily sol. in neutral or acid solns., but is readily sol. in aq. solns. of NH<sub>4</sub>OH + NH<sub>4</sub>Cl. The presence of Hg may be shown by boiling with HCl. *Apinol* is obtained by dry distn. of the wood of *Pinus palustris* or *P. australis*, and frac-

tionating, collecting and purifying the fraction 182.2° to 193.3°. The resulting amber-colored oil has d. 0.946 and b. 182.2° approx.; hence is chiefly *l*-menthone,  $C_{10}H_{18}O$ . It is an expectorant, antiseptic, and local anesthetic, useful in burns and ulcers, allaying pain, and promoting cicatrization of wounds. Internally it is probably also useful in catarrhal inflammation of the digestive tube (max. dose 1 cc.) and for inhaling purposes. *Apothesine*: A local anesthetic, used in 0.5% soln. of 0.4% NaCl containing adrenaline. Its chem. name is cinnamyl-diethylaminopropinol-HCl. *Brovadol* is bornyl Br-isovalerianate, an oily, colorless liquid of feebly aromatic odor,  $b_10$  163°, insol. in  $H_2O$ , sol. in EtOH,  $CHCl_3$  and  $Et_2O$ , containing 25.2% Br. It is used as a sedative for the nervous system. *Diemenal*: A soln. containing colloidal Mn, and used in treatment of malaria. *Elarson*, see C. A. 7, 866, 2065, 4013; 8, 1418; 9, 661. *Empyrom* is obtained by boiling birch tar with a soln. of HCHO, pouring the hot mixt. into HCl soln., cooling, collecting the solid mass and washing it free from the acid (Schering). It is a gray-brown powder, nearly odorless, insol. in  $H_2O$ , sol. in acetone and  $CHCl_3$ . It is antiprurient, sedative and siccative. It is recommended in eczema, psoriasis, urticaria, etc., in form of liniment containing 10% or it may be mixed with ZnO paste; or it may be used in the form of a 10% or 20% tincture. *Formicine*:  $AcNHCH_2OH$  is an equimol. compd. of HCHO and  $AcNH_2$ , a sirupy, slightly yellow liquid, with faint odor of HCHO and slightly acid, bitter taste, sol. in  $H_2O$ , EtOH,  $CHCl_3$ , glycerol, almost insol. in  $Et_2O$ . The solns., 1 to 5%, give off HCHO gradually at ordinary temp., hence are used as a local antiseptic; practically non-toxic; 5% solns. are but slightly irritant. *Glycarsenobenzol* is a mixt. of novarsenobenzol 0.2, guaiacol 0.1, stovaine 0.1 g. per cc., used by way of intramuscular injection in syphilis. *Ichthargan* has ichthyol as basis, with 30% Ag and 15% of organic S. To obtain it, neutralize ichthyol-sulfonic acid with  $Ag_2O$  and dissolve in  $H_2O$  the Ag salt formed. It is a brown, stable, amorphous powder, sol. in  $H_2O$ , glycerol, dil. EtOH, insol. in abs. EtOH,  $Et_2O$  and  $CHCl_3$ . It is thought to combine the properties of ichthyol with the antiseptic properties of Ag. It is decomposed by light and by chlorides. *Procaine*: The name given to novocaine made in U. S. *Sabromine*, or Ca-diBr-behenate,  $(C_{21}H_{41}Br_2COO)_2Ca$  is a colorless, odorless, insipid powder, insol. in  $H_2O$ , EtOH, sol. in  $Et_2O$ ,  $Me_2CO$ , PhH, ligroin and  $CCl_4$ . To prep. it, treat erucic acid with Br and convert into the Ca salt. It is a substitute for bromides, being less irritant than these to the mucous membrane of the stomach. Its action is not as rapid, but more prolonged. In the stomach, di-Br behenic acid is set free, which is absorbed in the intestine. *Siomine* is  $I_4$ -urotropic, containing 78.5% I; a substitute for org. I compds. *Sofos*: An effervescent mixt. of  $NaH_2PO_4$  and  $NaHCO_3$ , stabilized by coating one of these with  $Na_2HPO_4$ ; cf. C. A. 11, 2024. *Thermodine*,  $p-EtOC_6H_4NAcCO_2Et$ , is colorless, cryst., insol. in cold  $H_2O$ , and used as an analgesic, antipyretic and antiseptic in typhoid fever, pneumonia, influenza and tuberculosis. Though claimed to be non-toxic, it probably shares the harmful effects of other phenetidine derivs. *Triphenine*,  $p-C_6H_4OEt.NH.COEt$ , a white cryst. odorless, feebly bitter powder, m. 120°, nearly insol. in  $H_2O$ , sol. in EtOH and  $Et_2O$ , antipyretic, analgesic and hypnotic, of slower action than phenacetine. This compd. must also be used prudently; C. A. 10, 480. *Uropherine-B* is a double salt of Li benzoate and lithiated theobromine containing 50% of the latter; it is sol. in 5 parts of  $H_2O$  and is used as a diuretic in dropsy, nephritis, etc. *Uropherine-S* differs from the preceding in that Li salicylate takes the place of Li benzoate. The properties and uses are the same. *Double citrate of Sodium and Thorium* is used in radiology on account of its opacity to X-rays. Dissolve 10 g.  $Th(NO_3)_4$  in warm, boiled-out  $H_2O$ , add 30 cc. of a 50% aq. soln. of Na citrate; the ppt. formed at first is redissolved. Neutralize exactly with *N* NaOH and dil. to 100 cc. with  $H_2O$ , filter and sterilize.

S. WALDBOTT.

**The reactions of gold fish to certain habit-forming drugs—the use of the gradient tank.** V. E. SHELFORD. *J. Am. Pharm. Assoc.* 7, 597-603(1918).—The craving engendered by the use of habit-forming drugs is not understood. Most of the pharmacologic studies on habit-forming drugs have been made on mammals (a few have been on frogs) but almost none on the lower vertebrates. By chance S. discovered that fishes are peculiarly affected by numerous org. substances in aq. soln. when put under special exptl. conditions. The conditions are established in a tank 122 cm. long, 15 cm. wide and 13 cm. deep, in which water containing a drug flows into one end and out at both top and bottom, at the middle, while water which contains none of the drug flows into the other end at the same rate. The two flows meet at the middle and with most substances there is a mixt. of the two kinds of water which occupies the center third of the tank. In this mixt. a fish moving from the pure water end toward the drug-containing end encounters a gradual rise in concn. of the drug. This region of change of concn. is called the gradient. The character of the gradient in these tanks has been fully detd. by taking samples, by measuring cond., and by the use of colored water. If a fish encounters no change in water, it moves freely back and forth without showing preference for either end of the tank. If it encounters water containing an excess of  $\text{CO}_2$ , it backs away and starts again, often repeating the operation before going forward. It gives other evidence of stimulation. The opercles are lifted, the lower jaw protruded, or the mouth moved in a yawning, coughing or gulping motion. When a fish enters a soln. containing EtOH, cocaine, morphine or any one of several other substances tried, there is no apparent rejection of the drug, but on the contrary, after a time the fish is found to have a preference for the drug-containing end of the tank. With cocaine-HCl the fishes, after a short exposure, refused to leave the drug soln., soon became intoxicated and died. With EtOH the fishes reacted more and more positively as the concn. increased up to 10%. The expt. was discontinued because the subjects became semi-intoxicated. In 20% EtOH the fishes avoided the full strength but still reacted positively. With morphine-HCl no preference is shown in concns. of 0.15 g. per l. In 1 g. per l. positive preference was shown by one individual but not by another. Some individuals avoided the strongest solns. of morphine. With naphthalene in half-satd. and in satd. solns., the fishes reacted positively although they died after a time. Some species of minnows were less sensitive to EtOH than goldfish. A tadpole in 20% EtOH showed a positive reaction. The gradient tank may afford a valuable means of studying "habit" formation and of investigating compns. or combinations of drugs to det. those having the desired therapeutic effects with the least danger of habit formation.

L. E. WARREN.

**Inversion of sugar in U. S. P. sirup.** G. W. L. PLETTE. *J. Am. Pharm. Assoc.* 7, 609-10(1918).—Specimens of sirup were made by the "hot" and the "cold" methods, stored under various conditions of light and temp. for several months, and the amt. of invert sugar was detd. from time to time. The specimens stored in a cool, dark place were inverted the least and showed less yeasts and molds. *Penicillium glaucum* is believed to be the chief cause of the inversion. P. concludes that sirup should be stored in full bottles in a cool, dark place and shaken daily. The rate and the amt. of inversion are apparently independent of whether the hot or the cold method of prepn. has been used.

### Distinctive properties and classification of organic and colloidal silver compounds.

T. SOLLMANN. *J. Am. Pharm. Assoc.* 7, 677-86(1918).—By an extensive investigation which included a consideration of the appearance, the total Ag present, the irritation to the nostrils and conjunctival sac produced by a 10% soln., tests for pptn. with egg albumin, color of the filtrate after treatment of the soln. with hydrated Al silicate (Lloyd's reagent), tests for free Ag ions, soly., viscosity and d. of 25% soln., color of 1-1000 soln. compared with 0.1 N  $K_2Cr_2O_7$ , transparency by reflected light, Ag color index and nature of the protein, the various colloidal Ag compds. of the market were classified into groups. The *Collargol group* comprizes Collargol and Cargentos; the *Argyrol group*, Argyrol, Squibb's Silver Protein, Sophol, Silvol and Solargentum; the *Protargol group*, Protargol, Roche's Silver Protein, Heyden Silver Protein and Hegenon; the *free silver group*, Albargin and Roche's Silver Nucleinate; and the *pale group*, Novargan and Argonin. The results are tabulated. L. E. WARREN.

### Standardization of pituitary extract and other drugs. REYNOLD A. SPAETH.

Yale Univ. *J. Pharmacol.* 11, 209-20(1918); *Physiol. Abstracts* 3, 331.—A method is described, in which the "killiefish" or mummrechog, *F. heteroclitus*, a common minnow of the Atlantic coast is used. When a scale with widely expanded melanophores is placed in a pituitary soln. the melanophores contract completely, the time required being a function of the concentration of the extracts. KCl is used as a standard. Details are given. C. J. WEST.

The course of digitalis poisoning in the frog as a method of evaluation of digitalis preparations. R. GOTTLIEB. *Arch. exp. path. pharm.* 83, 117-56; *Physiol. Abstracts* 3, 272.—The stillstand of the frog's ventricle after injection of active digitalis glucosides passes off after a variable time especially in summer frogs. A detoxication must therefore occur in the frog's body somewhere. Differences in recovery time are noted in relation to mode of administration (subcutaneous, intravenous) and with the glucoside employed or its solvent and the method is suggested as a means of evaluation of preps. C. J. WEST.

Cresol preparations. C. A. NICORESTI. *Brit.* 118,667, Sept. 3, 1917. Cresol and mixts. of cresol and HCHO are solidified by the addition of Na stearate or animal soap and cast into tablets to be dissolved in  $H_2O$  or alc. for disinfecting and medicinal purposes. Crude or refined cresol is incorporated with about 10% of its wt. of stearate by heating to the b. p. with or without the application of pressure. The mixt. of cresol and HCHO to be similarly solidified may be prepd. by the addition of formalin soln. to the cresol, or by submitting the cresol to a current of HCHO gas until it has absorbed a tenth of its wt. Coloring and perfuming ingredients, such as oil of roses, may be added. According to the provisional specification, fatty acid and alkali may be added to sep. portions of the cresol, to be mixed and heated afterwards, and small quantities of wax or hard paraffin may be added to accelerate the process of solidification.

### Synthetic adrenaline. NAGAYOSHI NAGAI. *Brit.* 118,298, July 13, 1917.

Adrenaline is obtained by the following synthesis: (1) Diacetylprotocatechuic aldehyde, prepd. by the reaction of  $AcCl$  or  $Ac_2O$  on protocatechuic aldehyde, is condensed with nitromethane in the presence of weak inorg. or org. bases; (2) the resulting diacetyldihydroxyphenylnitroethanol is reduced in the presence of HCHO by means of Zn dust and HOAc; (3) the diacetyladrenaline so formed is hydrolyzed by HCl, giving adrenaline hydrochloride.

## 18. ACIDS, ALKALIES, SALTS AND SUNDRIES.

T. LYNTON BRIGGS.

**Mining and calcining magnesite in Napa, California.** ANON. *Mining Sci. Press* 117, 459-60(1918).—In 1917, Napa Co., Cal., contributed 19% (40,218 tons) of the total crude magnesite mined in California. The White Rock Mine at Napa is situated at an elevation of 1200 ft. and is 500 ft. above the calcining plant. All broken ore passes down chutes to the adit. From the outlet of the mine the ore is run over a 2" grizzly. The oversize goes directly to the kilns. The undersize goes to a revolving trommel with 1 1/4" perforations. The oversize from this goes to the kilns and the undersize is dumped on a 1 1/4" shaking wire screen. What passes through this is discarded, being high in SiO<sub>2</sub> content. Between the mine and the calcining plant, a distance of 5000 ft., is a 500 ft. fall. An aerial tram carries the ore to the kilns. The crude ore analyzes SiO<sub>2</sub> 1.94%, Fe<sub>2</sub>O<sub>3</sub> 1.49%, CaO 0.67%, MgO 45.01%, CO<sub>2</sub> 50.65%. The calcining plant consists of 11 vertical kilns having steel jackets lined with 13" of fire-brick. Alternate layers of coke and MgCO<sub>3</sub> in the proportion of 1 to 12 are dumped into the kilns from the charging floor. Natural draft suffices to burn the ore in 24 hrs. The burned ore analyzes SiO<sub>2</sub> 4.60%, Fe<sub>2</sub>O<sub>3</sub> + Al<sub>2</sub>O<sub>3</sub> 4.46%, CaO none, MgO 90.46% and loss on ignition 0.48%. The MgO produced being high in Fe<sub>2</sub>O<sub>3</sub> is desirable for refractory purposes. The mine produces monthly 3500 tons of crude MgCO<sub>3</sub> and 1750 tons of calcined product. E. A. TSCHUDY.

**The potash industry of Germany.** W. SAVAGE. *Chem. Met. Eng.* 19, 453-6 (1918).—A brief review, with analytical data, soly. curves, diagrams, statistical data, etc. The theories of the origin of the Stassfurt deposit, a description of the deposit, the present status of the industry and its economic aspect are considered.

**Recovery of potash from kelp.** C. A. HIGGINS. *J. Ind. Eng. Chem.* 10, 832-3 (1918); *Chem. Met. Eng.* 19, 432-3(1918).—A brief review and discussion, followed by an outline of the process used by the Hercules Powder Co.

F. W. SMITHER.

**The kelp-potash plant of the Lorned Manufacturing Company.** L. H. THOMPSON. *Chem. Met. Eng.* 19, 450-2(1918).—A description, with illustrations, of the plant and its operation. About 6 tons per day of a product (a grayish charcoal) containing 35% K<sub>2</sub>O are produced, other possible products being lost by the method used (drying and incinerating). The output of the plant is sold as a fertilizer. Furnace gases and moisture are drawn off from the rotary dryers by suction fans placed at the discharge end. A similar fan is used at the end of the incinerators (oil-fired) to produce a draft necessary to complete combustion. The flues from the dryers and incinerators lead to a series of brick chambers where the velocity of the dust-laden gases is reduced to such a point that nearly all the dust is pptd. At the end of the dust chamber the smoke passes through sprinklers to wash it thoroughly before allowing it to escape into the air. An av. of 15 tons of dust, having a content of 30% K<sub>2</sub>O, is recovered from the dust chambers each month.

F. W. SMITHER.

**A wet process for extracting potash from cement dust.** J. G. DEAN. *Chem. Met. Eng.* 19, 439-47(1918).—A detailed description, with drawings, curves, flow sheets, calcs., etc., of an exptl. plant operated by the Southwestern Portland Cement Co. at Victorville, Calif., for the pptn. of K-bearing dust from cement kilns by a humidifying process. One ton of K<sub>2</sub>SO<sub>4</sub> is made per day. From the data obtained, a permanent installation has been designed. A diagrammatic layout and a flow sheet of the proposed permanent installation are shown. The chemistry of the process is outlined as follows: "The K and Na in the feldspar and other minerals contained in the cement rock mixt. are volatilized as oxides to a certain extent by the intense heat in the clinker-

ing zone, and probably react with  $\text{SO}_2$  (formed from S in the fuel) to form sulfates. After these reactions take place near the focus, if the sulfates pass on into a reducing atm. (CO) sulfides will be formed. Thiosulfates and carbonates are also formed in the hot, humid gases. On reaching the spray chamber, the gases bear particles of fume consisting in part of K and Na sulfides, sulfates, and thiosulfates, together with some complex polysulfides. The  $\text{H}_2\text{O}$  which washes these particles out of the gas also absorbs  $\text{CO}_2$ , forming some bicarbonates; these latter rapidly oxidize any remaining sulfides ( $\text{K}_2\text{S} + 2\text{KHCO}_3 = 2\text{K}_2\text{CO}_3 + \text{H}_2\text{S}$ ). The  $\text{H}_2\text{S}$  rapidly hydrolyzes to  $\text{H}_2\text{O}$  and S, which latter reacts with any sulfite, which may rarely be present ( $2\text{Na}_2\text{SO}_3 + 2\text{S} = 2\text{Na}_2\text{S}_2\text{O}_3$ ). A considerable quantity of this S also condenses on the sides of the stack through which the spent, cool kiln gases eventually escape. Therefore, the mixed spray chamber sludge and condensate contain in soln. principally the following ions:  $\text{Na}^+$ ,  $\text{K}^+$ ,  $\text{CO}_3^{--}$ ,  $\text{S}_2\text{O}_3^{--}$ , and  $\text{SO}_4^{--}$ . The solns. are drawn through a bed of gypsum to remove the  $\text{CO}_3^{--}$ , the  $\text{CaCO}_3$  formed being insol. To prevent overloading the evapg. system with  $\text{CaSO}_4$  (which is sol. in thiosulfate), a little  $\text{CO}_3^{--}$  should remain in the soln. after gypsum treatment (this is carried out under chem. control). On evapg. the soln. the double salt  $\text{K}_2\text{S}_2\text{O}_3 \cdot \text{Na}_2\text{S}_2\text{O}_3 \cdot 1/2$  to  $1 1/2$   $\text{H}_2\text{O}$  is obtained, together with  $\text{K}_2\text{SO}_4$ . In actual practice the salts as they come from the crystallizer-evaporator are dried and heated to remove a part of the S of the thiosulfates, giving a product of about 90%  $\text{K}_2\text{SO}_4$ . The formation of the double thiosulfates can be prevented by adding enough  $\text{Na}_2\text{SO}_4$  to furnish the necessary amt. of  $\text{SO}_4^{--}$  for the  $\text{K}^+$  present in excess. This salt also furnishes the requisite amt. of  $\text{Na}^+$  for the  $\text{S}_2\text{O}_3^{--}$ . Pure  $\text{K}_2\text{SO}_4$  will then crystallize from boiling solns. up to the point of satn. of the Na salt. Now if these hot solns. are drained into a crystallizing tank and allowed to cool,  $\text{Na}_2\text{S}_2\text{O}_3 \cdot 5\text{H}_2\text{O}$  will crystallize, while the  $\text{K}_2\text{SO}_4$  remaining in the mother liquor can be returned to the primary evaporator."

F. W. SMITHER.

**Recovery of potash from iron blast furnaces and cement kilns by electrical precipitation.** L. BRADLEY. *J. Ind. Eng. Chem.* 10, 834-8(1918); *Chem. Met. Eng.* 19, 457-60(1918).—A review and discussion with analytical data, calns., costs, etc. A bibliography is appended.

F. W. SMITHER.

**Potash from desert lakes and alunite.** J. W. HORNSEY. *J. Ind. Eng. Chem.* 10, 838-9(1918); *Chem. Met. Eng.* 19, 461-2(1918).—A brief review and discussion.

F. W. SMITHER.

**Potash as a by-product.** J. S. GRASTY. *Chem. Met. Eng.* 19, 434-8(1918).—A detailed review and discussion, with illustrations, analysis of raw materials, estd. cost of operation, probable recovery and profits, of the value of Southern Fe ores and fluxes as a domestic source of  $\text{K}_2\text{O}$  in large quantities. The only large tonnage of K-bearing Fe ores known in this country occurs in eastern Ala. The ores of the Weewooka and Eumauhee districts contain 1.5 to 3.0%  $\text{K}_2\text{O}$ , those of the Columbiana district, 1.0 to 1.25%  $\text{K}_2\text{O}$ .

F. W. SMITHER.

**Potash in Nebraska.** J. M. LLITERAS. *Chem. Met. Eng.* 19, 633-4(1918).—A brief review of the conditions at the plants producing K salts from lake brines. Nebraska is now producing about 450 tons of salts daily, with an av.  $\text{K}_2\text{O}$  content of 25%. This production is expected to be further increased in the near future. Cf. Thum, C. A. 12, 296; Norris, C. A. 12, 1035.

F. W. SMITHER.

**Potash from Searles Lake.** A. DE ROFF, JR. *J. Ind. Eng. Chem.* 10, 839-44(1918); *Chem. Met. Eng.* 19, 425-31(1918).—A detailed description, with illustrations, analytical and statistical data, etc., of the American Trona Corp'n.'s operations and plant. With recently installed equipment, the company will produce about 4500 tons of K salts per month, analyzing from 75 to 80% KCl and containing less than

3.5% borax. By the first of 1919 there will be a daily output of 40 to 50 tons of refined borax (99.5%  $\text{Na}_2\text{B}_4\text{O}_7 \cdot 10\text{H}_2\text{O}$ ). F. W. SMITHER.

**Hydrogen peroxide.** J. FRÈRE. *Rev. prod. chim.* 21, 211-4(1918).—A review and discussion of the patented processes for the manuf. of  $\text{H}_2\text{O}_2$ , e. g., the Thénard ( $\text{BaO}_2$ ) process and its modifications, the use of  $\text{Na}_2\text{O}_2$ , persulfates, percarbonates, perborates, direct synthesis, catalytic processes, prepn. of pure  $\text{H}_2\text{O}_2$  from the industrial product, distn., and stabilization. The article cannot very well be abstracted. F. W. S.

**Synthetic nitrogen products.** G. MORSELLI. *Chem. Trade J.* 63, 182(1918).—The cyanamide industry underwent extensive expansion during the first two years of the war. In 1914 the production was 194,762 tons and in 1916, 981,500 tons. In Italy the production of synthetic  $\text{HNO}_3$  has remained stationery and that of  $\text{CaCN}_2$  has not greatly increased. The arc process is only of value in countries like Norway where the cost of installation is \$40.00 per H. P. and the working expenses \$1.50 to \$2.00 per H. P. per annum. In Italy the corresponding figures are \$200 to \$300 and from \$15.50 to \$20.00, respectively. The cyanamide process offers great advantages despite the difficulty represented by the coal problem, which is serious in Italy. The Haber process seems to have been surpassed by the method of the General Chem. Co. which directly synthesizes  $\text{NH}_3$  from N and H. This company produces H very cheaply and this is of the greatest importance for the synthesis of  $\text{NH}_3$ . As Germany in future will not purchase any natural nitrate, and England, France, Italy and the U. S. are seeking to become independent of nitrate, the Chilean Govt. will probably be compelled to discontinue the export duty provisionally, either partially or entirely and the price will perhaps fall. The result of this would be to stimulate the Italian N industry to utilize the cheapest hydro-elec. power and the most economical methods of production.

E. A. TSCHUDY.

**The Salters' Institute of Industrial Chemistry.** ANON. *Nature* 102, 147-8 (1918).—A review is given of the announcement by the Salters' Company of an institute to be established for the promotion of scientific education and research by the provision of fellowships tenable by graduate workers.

ALBERT R. MERZ.

**Chemical products and processes.** WM. A. TILDEN. *J. Soc. Dyers Colourists* 34, 199-200(1918); *British Sci. Products Exhibition Catalogue* p. 7.—The subject is discussed under (1) heavy chemicals; (2) fine chemicals; (3) application of chemistry to arts and manufactures. In the 1st British manufacturers had maintained the lead but Germany had gradually developed almost a complete monopoly upon the 2nd at the beginning of war, and the position of the British chemical industry in August 1914 was very serious. British chemists and manufacturers have arisen to the occasion and the country is now receiving all that is essential in dyes, drugs, and chemicals. In the 3rd the chief developments have been in production of H for air ships, fixation of N, hardening of oils by hydrogenation, production of synthetic drugs including organo-arsenic compds., poisonous gases for warfare and recovering of K from waste furnace gases.

L. A. OLNEY.

**Calculation of extraction in continuous agitation.** A. HAM AND H. S. COE. *Chem. Met. Eng.* 19, 663-6(1918).—The authors show the derivation of a mathematical formula for continuous systems of extn. in hydrometallurgy and industrial chemistry, and give examples of its application.

F. W. SMITHER.

**The use of microorganisms in chemical industry.** E. G. GENOUD. *Chem. Met. Eng.* 19, 616-7(1918).—An account of the application of yeasts, molds and bacteria in industrial org. chemistry with an outline of future possibilities that await research. The subjects treated include alc. fermentation and lactic and butyric acid manuf.

E. A. TSCHUDY.

Determination of nitrates in caliche and its products (CLENNELL) 7. Useful substances from corn cobs (LA FORGE) 28.

**Sodium aluminate, sodium carbonate, and alumina.** E. E. DUTT and P. C. DUTT. Brit. 118,156, Aug. 18, 1917. A mixt. comprizing specified proportions of calcined bauxite or like aluminous substance,  $\text{NaCl}$ ,  $\text{Ca(OH)}_2$ , and C is heated in a muffle to dull redness and submitted to the action of the vapor of  $\text{As}_2\text{O}_3$ . The charge from the muffle is lixiviated with  $\text{H}_2\text{O}$ , yielding a soln. of Na aluminate which may be evapd. to dryness and obtained as such or may be treated with  $\text{CO}_2$  to yield a ppt. of  $\text{Al(OH)}_3$  and a soln. of  $\text{Na}_2\text{CO}_3$ . The  $\text{Al(OH)}_3$  is washed, dried, and calcined, yielding  $\text{Al}_2\text{O}_3$ , and the  $\text{Na}_2\text{CO}_3$  soln. evapd. to dryness.

**Alkali cyanides.** G. CALVERT. Brit. 116,365, June 12, 1917. In the production of alkali cyanides by the reaction of N and C on an alkali metal or alkali metal compd. in the presence of Fe, the metal catalyst is produced *in situ* from Fe carbonyl, which may be prepd. in admixt. with N by passing producer gas over finely divided Fe or may be sep. prepd. and introduced into the reaction. A suitable app. is specified.

**Ammonium sulfate.** T. TURIYAMA. Brit. 116,321, May 31, 1917.  $\text{NH}_3$  and  $\text{CO}_2$  are introduced into  $\text{Na}_2\text{SO}_4$  soln.;  $\text{NaHCO}_3$  seps.  $\text{H}_2\text{SO}_4$  is added to the mother liquor to convert dissolved bicarbonate and free  $\text{NH}_3$  into sulfates, and the soln. is then evapd. and cooled to sep. out the  $\text{Na}_2\text{SO}_4$ , which is used again, leaving  $(\text{NH}_4)_2\text{SO}_4$  in soln.

**Aluminium chloride; alumina.** R. WELFORD. Brit. 118,312, Aug. 18, 1917. Clay, bauxite, or the like, which may be dried at a low temp., is heated with  $\text{HCl}$  to dissolve the Al. The soln. sepd. from the residues may be purified, and is evapd. to dryness. The crystals are then further heated with steam to produce  $\text{Al}_2\text{O}_3$ , the  $\text{HCl}$  expelled being recovered. Al may be obtained by known methods from the  $\text{Al}_2\text{O}_3$ .

**Alumina.** MINERAL PRODUCTS CORPORATION. Brit. 118,063, Feb. 27, 1918. Impure  $\text{Al}_2\text{O}_3$  resulting from the calcination and leaching of alunite is purified by mixing it in a finely divided condition with  $\text{H}_2\text{O}$  to form a pulp, and subjecting the pulp to a flotation process in any suitable app. such as a Callow, Hoover, or Janney cell, with or without the use of a frothing agent, such as oleic acid.

**Potassium aluminate, potassium carbonate, and alumina.** E. E. DUTT and P. C. DUTT. Brit. 118,155, Aug. 18, 1917. A mixt. comprizing specified proportions of calcined bauxite or like aluminous substance,  $\text{KCl}$ ,  $\text{Ca(OH)}_2$ , and C is heated in a muffle to dull redness and submitted to the action of the vapor of  $\text{As}_2\text{O}_3$ . The charge from the muffle is lixiviated with  $\text{H}_2\text{O}$ , yielding a soln. of K aluminate which may be evapd. to dryness and obtained as such or may be treated with  $\text{CO}_2$  to yield a ppt. of  $\text{Al(OH)}_3$  and a soln. of  $\text{K}_2\text{CO}_3$ . The  $\text{Al(OH)}_3$  is sepd. and the  $\text{K}_2\text{CO}_3$  soln. evapd. to dryness.

**Drying salt.** T. W. S. HUTCHINS. ELECTRO-BLEACH & BY-PRODUCTS, LTD. Brit. 118,712, Oct. 5, 1917.  $\text{NaCl}$  is dried in app. consisting of a series of superimposed heated cylinders through which it is successively traversed by high-speed rotary conveyers. Details of construction and operation are specified.

**Decolorizing carbon.** H. M. SHILSTONE. Brit. 116,253, July 26, 1917. Decolorizing C is formed by carbonizing fibrous cereal material, rich in  $\text{SiO}_2$ , such as rice hulls, straw, or chaff, wheat or oat straw, esparto, outer shells of corn stalks, sugarcane fibers, etc., by heating gradually to a glowing redness out of contact with O. The carbonized material is boiled with an alk. material such as  $\text{NaOH}$  or  $\text{Ca(OH)}_2$ ,  $\text{MgO}$ , or carbonates of alkali metals or alk.-earth metals, to dissolve out resinous matters, and is then washed and boiled with acid. When alk.-earth oxides or car-

bonates are used these may be mixed with the materials before carbonization. The decolorizing carbons may be used for decolorizing sugar-cane juices in neutral or alk. soln., and to remove the polyphenols and tannins from the juices. Cf. 21,204, 1911 (C. A. 7, 1115), 19,357 1912 (C. A. 8, 557), and 17,432, 1913 (C. A. 9, 697).

**Zinc oxide.** H. MACONCHIE. Brit. 118,665, Sept. 1, 1917. ZnO is produced by blowing heated air or O on to or into melted Zn or a mixt. contg. Zn, the supply of heat being discontinued when the reaction has started. The process may be combined with the extn. of Zn from ZnS ore by means of Fe, the ZnS being mixed with scrap Fe and melted, and the heated air being blown upon or into the molten mass. Additional quantities of Zn or Zn ore and Fe are added gradually to avoid lowering the temp., and may be preheated. The heating of the reaction mass may be effected by an oil burner or by an elec. resistance. Additional air may be supplied to the oxide fume to complete the oxidation. The surplus heat of reaction is used to heat, in an adjacent chamber adapted for the purpose, the air required for the reaction.

**Tin oxide.** H. MACONCHIE. Brit. 118,664, Sept. 1, 1917. SnO<sub>2</sub> is obtained by blowing heated air or O upon or into melted Sn, the supply of heat being stopped when the reaction has started. The Sn may be melted by an oil burner or an elec. resistance, and the air and additional Sn may be preheated by the heat of reaction.

**Titanium products; pigments.** TITAN & CO. Brit. 116,266, Apr. 10, 1918. Materials for use as pigments, and for other purposes such as for heat-insulating or for ceramic use, are made from Ti hydroxides which have been pptd. from sulfate or other acid solns., and so contain H<sub>2</sub>SO<sub>4</sub> or other acid by treatment with basic material, such as CaCO<sub>3</sub>, to produce an insol. sulfate, etc. The reaction should be accompanied by the evolution of gas, to render the product porous and homogeneous. The proportion of basic substance may be altered in order to obtain, after calcination, a product contg. some Ca titanate, if desired. Where the mixt. of Ti compd. and CaSO<sub>4</sub> is to be used as a pigment, it is calcined to drive off the H<sub>2</sub>O of hydration, and calcination is continued until the Ti oxide is converted into a cryst. modification.

**Separating solids from liquids.** N. PEDERSEN. Brit. 119,028, Aug. 1, 1918. Solid particles are sepd. from liquid in which they are suspended by means of air or gas bubbles, the air or gas being introduced into the liquid under pressure and liberated at atm. pressure. The process is applicable to the sepn. of wood fibers from the effluent H<sub>2</sub>O from wood pulp plant, and to known methods of sepg. ores.

**Dental cements.** W. S. CROWELL. Brit. 118,701, Sept. 26, 1917. Ag salts are incorporated with dental cements for tooth-stopping or for setting crowns, etc., so as to exert antiseptic effects and to prevent the recurrence of decay. Ag<sub>3</sub>PO<sub>4</sub> may be mixed with the powder of an ordinary Zn hydroxyphosphate cement, or the phosphate, carbonate, oxide, or other salt of Ag may be dissolved in the H<sub>3</sub>PO<sub>4</sub> soln. with which the cement powder is mixed for use. This soln. may also contain Zn<sub>3</sub>(PO<sub>4</sub>)<sub>2</sub>, AlPO<sub>4</sub>, and Na<sub>2</sub>HPO<sub>4</sub>. In place of Ag<sub>3</sub>PO<sub>4</sub>, other salts such as borate, silicate, chloride, bromide, or iodide may be employed.

**Dental cements.** W. S. CROWELL. Brit. 118,702, Sept. 26, 1917. Hg salts are incorporated with dental cements for tooth-stopping and for setting crowns, etc., so as to exert an antiseptic action and to prevent the recurrence of decay. A Hg phosphate or other mercurous or mercuric compd., such as an oxide, sulfide, chromate, or carbonate, is added to the powder or to the H<sub>3</sub>PO<sub>4</sub> soln. of an ordinary hydroxyphosphate of Zn cement. The acid soln. may contain in addition, the phosphates or oxides of Na, Zn, or Al.

**Abrasives.** NORTON CO. Brit. 118,591, Feb. 7, 1918. An aluminous abrasive having a weak grain and contg. crystals which are perforated or cellular is obtained

by fusing an aluminous material with a small proportion of a substance capable of existing in the vapor phase at the temp. at which the charge solidifies. The substances used comprize Na, K, or other alkali metal compds., such as  $\text{Na}_2\text{CO}_3$ ,  $\text{Na}_2\text{SO}_4$ ,  $\text{NaAlO}_2$ ,  $\text{AlF}_3$ , and Zn powder. From 1 to 5% of the Na compd., reckoned as  $\text{Na}_2\text{O}$ , is used. The aluminous material may consist of pure  $\text{Al}_2\text{O}_3$ ,  $\text{Al}_2\text{O}_3$  contg.  $\text{SiO}_2$ , or bauxite.

**Abrasives.** NORTON CO. Brit. 118,592, Feb. 7, 1918. An aluminous abrasive having a fine grain of weak structure is obtained by fusing bauxite with a small proportion, *e. g.*, 2-3%, of an alkali metal compd. Soda ash is preferred, but the sulfates, carbonates, hydroxides, or aluminates of Na or K may be used. The proportion of the impurities present in the bauxite, namely  $\text{SiO}_2$ ,  $\text{Fe}_2\text{O}_3$ , and  $\text{TiO}_2$ , may be reduced by incorporating in the charge a quantity of coke or other form of C.

**Plastic compositions.** R. Y. ARDAGH. Brit. 118,768, Jan. 4, 1918. Silicate cotton is prepd. for admixt. with a soln. of Na or K silicate by first sepg. it into three grades, namely (1) wool fiber; (2) "vitric metalline globules, being the heavy mineral matter ranging in size from a grain of wheat to a grain of sand;" (3) slag dross and vitrified coke-like pieces. Nos. 1 and 2 only are utilized, being comminuted separately before mixing with a soln. of water-glass, etc., of 70° Tw. The compn. may be spread over inflammable and flexible materials to convert them into stiff sheets, or may be molded into boards, etc., or poured into molds of wire netting encased by cardboard, bast matting, etc., or between sheet linings for ship and like construction. The compn. may be mixed with granulated and like materials such as sawdust, cork, spent tar, coconut fiber, peat fiber, and other vegetable fibers.

**Washing coal, ores, etc.** T. M. CHANCE. Brit. 119,038, Sept. 9, 1918. Materials of different sp. gr. are washed, concd., or sepd. by means of an agitated fluid mixt. of a liquid such as  $\text{H}_2\text{O}$  and a granular solid such as sand surmounted by a body of liquid such as  $\text{H}_2\text{O}$ . A suitable app. is specified.

**Metal polish.** W. H. ALLEN. U. S. 1,280,939, Oct. 8. A mixt. for coating and polishing Fe or other metals is formed of graphite 16, lampblack 3 parts and sufficient dil.  $\text{H}_3\text{PO}_4$  to form a thin paste.

**Heat-insulating material.** J. K. TOLLS. U. S. 1,281,097, Oct. 8. Rice straw is partially purified by treatment with a dil. alkali soln. and heating, washed, mixed with uncooked material such as chopped tule in  $\text{H}_2\text{O}$  and the mixt. is formed into sheets for use as a heat-insulating material.

## 20. CEMENT AND OTHER BUILDING MATERIALS.

C. N. WILEY.

**Wear-resisting values of various aggregates for concrete roads indicated.** H. S. MATTIMORE. *Eng. News-Rec.* 80, 861(1918).—Tests were made with a machine designed to generate impact stresses which parallel those set up by traffic. Summary of results indicated that (1) crushed stone remains intact and resists impact better than gravel; (2) although a good matrix has a tendency to support a weak coarse aggregate the use of a good quality of the latter will make a more durable pavement; (3) a coarse-grained mortar resists impact better than a mortar made with finer-grained sand.

H. A. BRIGHT.

**Portland cement construction for chemical works.** M. TOCH. *Chem. Met. Eng.* 19, 487(1918).—Through the use of special coatings portland cement is being used extensively in chem. works. Concrete finished with acid-proof brick linings set in a heavy bituminous binding material is used for acid storage and niter cake.

H. A. BRIGHT.

**Reinforced concrete versus salt, brine and sea water.** H. J. M. CREIGHTON. *Chem. Met. Eng.* 19, 618-23(1918).—Examples of failures of reinforced concrete are given, the cause being due to electrolytic corrosion of the reinforcing steel (cf. C. A. 12, 415). C. suggests the use of the Schoop metal-spraying process for waterproofing to prevent corrosion of reinforcement. H. A. BRIGHT.

**Electricity in the cement industry.** R. B. WILLIAMSON. *Elec. Rev. West Elec.* 73, 813-4(1918).—Contains many data of interest to chem. engineers. C. G. F.

**Recovery of potash from cement kilns (BRADLEY) 18.** Wet process of extracting potash from cement dust (DEAN) 18.

## 21. FUELS, GAS, TAR AND COKE.

J. D. PENNOCK.

**Remarks on the rule of Dulong.** C. T. S. *Het Gas* 38, 236-9(1918).—The Dulong formula for the calcn. of calorific value of coal, while not scientifically accurate, is sufficiently reliable for practical work. In most cases it can be made more accurate by regarding all the H as free and combustible (omitting the factor H/8), and by adding the factor 2500 S, to allow for the combustion of the S present. This gives it in the form  $(8080 C + 34500 H + 2500 S)/100$ , which gives higher figures than the old form. In most cases, this is in accord with facts. No accurate rule can be formulated till it can be established which constituents of coal are endothermic and which are exothermic. JULIAN F. SMITH.

**Use of the hydrogen-volatile-matter ratio in obtaining the net heating value of American coals.** A. C. FIELDNER AND W. A. SELVIG. *Bur. Mines Tech. Paper* 197, 13 pp.(1918).—The standard methods of analyzing coal as given by the Am. Soc. Testing Materials state that "the results of detns. of caloric power shall be stated either as 'total' heat of combustion or 'net' heat of combustion." Total heat of combustion is defined as the direct result obtained in the bomb calorimeter with the water vapor in the products of combustion condensed to liquid water at the temp. of the calorimeter, that is, from 20 to 30°. Net heat of combustion at 20° is defined as the heat developed on complete combustion of a unit wt. of fuel with the water in the products of combustion passing off as vapor at 20°, and is calcd. as follows: Net heat of combustion in cal. = total heat of combustion —  $[(\% H \times 9 \times 580)/100]$ . It is seen that the detn. of net heat of combustion involves a H detn. as well as a calorimetric one. Since the H content of coals is roughly proportional to the volatile matter present, it was thought that the H content of coals could be estd. accurately enough from the percentage of volatile matter. From the analyses of 2000 coals of wide occurrence, the relation existing between the H content and the volatile matter was established. By the use of curves showing this relation the H content of bituminous, semibituminous and anthracite coal may be estd. from the volatile matter to within 0.6%. For sub-bituminous coal and lignite the limits of deviation should be extended to 0.8%. In most coals the error in the net heat of combustion calcd. in the manner presented will not exceed 0.5%, which is no larger than errors incurred in sampling coal.

J. H. YOUNG.

**Coal economics.** G. BASTIEN. *L'Industrie chimique* 5, 221-5(1918).—A review and discussion (mainly mathematical) of the methods that have been proposed for the economical production of steam. F. W. SMITHER.

**Notes on lignite, its characteristics and utilization.** S. M. DARLING. U. S. Dept. Interior, Bur. Mines, *Tech. Paper* 178, 17 pp.(1918).—"This short summary of present information on the compn. and utilization of lignite is issued by the Bur. of

Mines for the purpose of outlining problems that are of immediate and urgent importance to the maintenance of industrial activity, and the upholding of the utmost efficiency in the conduct of the war." Cf. *C. A.* 11, 2536. F. W. SMITHER.

**Loss of volatile matter in the moisture determination in lignite.** H. L. KROFF. Amsterdam. *Hel Gas* 38, 233-4 (1918).—By quant. absorption of  $H_2O$  in  $CaCl_2$  tubes, it was found that part of the loss detd. as moisture is org. volatile matter. This amounted in 1 sample, after 6 days' air drying, to 1.3% of the wt. of the sample; and to 7.3% after oven drying at  $110^\circ$ . Probably the chief loss consists of volatile humus acids, with small amts. of  $CH_4$ . JULIAN F. SMITH.

**Partial separation of water and tar from lignite.** H. VAN DER WOUDE. *Hel Gas* 38, 234-6 (1918).—The chief objection to coking lignite is the large amt. of steam evolved, which causes difficulty of manipulation and lowers the quality of the  $NH_3$  liquor and the tar. By suitable arrangement of a battery of 4 ovens, with provision for drawing off the steam, it was found possible to obtain a good yield of a fair quality of gas by coking lignite in 3 ovens and a good coal in the other. With proper distn. facilities, the quality of the  $NH_3$  liquor and the tar can be maintained also.

JULIAN F. SMITH.

**Apparatus for measuring chimney heat loss, and the factors causing this loss.** MARCEL CHOPIN. *Compt. rend.* 167, 335-8 (1918).—An app. was designed for simultaneously measuring temp.,  $CO_2$  content of the flue gases, and heat loss in the flue. The heat loss is calcd. by the formula:  $P = K(T_2 - T_1)/A$ , in which  $P$  is the heat loss in % of the calorific value of the fuel used,  $T_1$  the temp. of air entering the furnace,  $T_2$  the temp. of the flue gas leaving the chimney,  $A$  the % of  $CO_2$  in the flue gas, and  $K$  a proportionality const. The  $CO_2$  content was measured by the change in elec. cond. of the  $NaOH$  absorbing soln. The app. is so arranged that the pyrometer and the  $CO_2$  indicator can be read simultaneously. The method is accurate enough for industrial work and yet does not require a technically trained expert. An automatic recording indicator of heat loss is being devised. IRENE F. SMITH.

**Low-rate combustion in fuel beds of hand-fired furnaces.** H. KREISINGER, C. E. AUGUSTINE AND S. H. KATZ. Bur. Mines, *Tech. Paper* 139, 54 pp. (1918).—This paper presents the results of a study of the process of combustion in the fuel bed of hand-fired furnace when burning coal at such low rates of combustion as are used in house-heating app. The study is an extension of the work previously reported (cf. *C. A.* 11, 1740) which covers the higher rates of combustion, such as are used in burning coal under power plant and locomotive boilers. That report deals with rates of combustion of 20 to 180 lbs. of coal per sq. ft. of grate per hr., whereas this paper covers the rates below 20 lbs. The same app. and largely the same methods were used in both cases. **Conclusions:** "The processes taking place in the fuel bed consist mainly of the gasification of the solid fuel. The  $O$  flowing up through the grate is all used as it passes through the first 3 or 4 in. of the fuel bed. The products of combustion in this part of the fuel bed are largely  $CO_2$ , and a smaller % of  $CO$ . At a height of 3 to 4 in. from the grate the  $CO_2$  content of the gases reaches a max. of 12 to 18%. As the  $CO_2$  passes through the upper layers of the fuel bed it is reduced to  $CO$ , which with the combustible gases distd. near the surface of the fuel bed constitutes 16 to 30% of the gases rising from the fuel bed. The ratio of the wt. of air that can be supplied through the grate to a lb. of coal gasified remains const. at about 7 to 1. The amt. of air supplied through the grate detd. only the rate of combustion and not its degree of completeness. For the complete combustion of 1 lb. of av. coal about 14 lbs. of air are necessary; however, as only 7 lbs. of air per lb. of coal can be supplied through the grate, another 7 lbs. must be supplied over the fuel bed in order that the gases rising from the fuel bed may be completely burned. This additional air should be

introduced close to the surface of the burning fuel and, if possible, in many fine streams. The process of combustion in the fuel bed is essentially the same whether firing is in small amts. at short intervals or in large quantities at long intervals. During the distn. period the % of combustible in the gases rising from the fuel bed is larger and more air must be supplied over the fuel bed at this stage. This requirement for a variable air supply over the fuel bed makes smokeless and economic burning of soft coal in hand-fired furnaces difficult. With the com. house-heating app. enough air to keep the fire going may leak into the ash pit when the ash-pit door is closed. Enough air to maintain combustion will not enter the fuel bed from the top surface. As the gases rising from the fuel-bed contain a large % of CO it is not advisable with hot-air furnaces to close entirely the damper in the smoke pipe, because CO may escape through defective joints into the air jacket and enter the rooms." Cf. C. A. 12, 1242.

F. W. SMITHER.

**Possibility of obtaining cheap fuel in Argentina.** CARLOS DIÁZ. *Univ. Tucumán inform. depart. investig. industri.* 1917, 35-44.—D. discusses the problem of cheap fuel in Argentina and suggests the advisability of using imported coal as raw material for building up a gas and coke by-products industry. The utilization of various by-products such as coal tar,  $C_6H_6$ ,  $NH_3$ , etc., is discussed from a technical standpoint.

H. S. PAINE.

**"Gasteam" plant at Ford City, Ontario.** ANON. *Power* 48, 186-93 (1918).—This paper describes a combination a. c. and d. c. plant employing "Gasteam" engines, the boiler feed water being used to recover waste heat from the gas engine cylinder jackets. The power units consist of a gas engine with tandem cylinders on one side of a d. c. generator, and a tandem compound Corliss engine on the other side. The exhaust from the gas engine is used to superheat the steam in the receiver which is between the high and low pressure cylinders of the steam engine. The layout of the machinery, boilers, producers, and arrangements for moving fuel to boiler furnaces and to producers are described. A new feature of the gas producer plant is the separation of the tar from the gas and its return to the producer where it is gasified with success. This method of tar disposal is more economical than the old method of burning under boilers. The gasified tar increased the heat value of the producer gas 16%, while the general gain in thermal efficiency was 8 to 9%. Exhaust steam is used to sat. the air blast to the producers, the temp. being thermostatically controlled to range between 60 and 65°. When the temp. runs below 60° there is apt to be clinker trouble, and if it exceeds 65° the production of  $CO_2$  increases. In the producer furnace fire, flame, soot, and holes up through the fire bed were avoided by having the grates inclined 35° rising from the back wall of the producer, and by specially training the firemen. The gas engines which had been previously run on natural gas containing 1000 B. t. u., took up the full load on producer gas which averaged 190 B. t. u.

L. W. RIGGS.

**The production of blue water gas in small gas works.** E. JACQUEMARD. *Het Gas* 38, 242-3 (1918).—Contrary to the prevailing opinion, it is possible for small gas plants to produce water gas at a profit. An installation is described for a capacity of 85-100 cu. m. per hr. Its initial cost is small, it can be operated by 1 man, and it yields gas which can be mixed with coal gas in as high a ratio as 40%. Thus a small plant can increase its gas production by 35-40%.

JULIAN F. SMITH.

**Physical study of the Welsbach mantle.** HERBERT E. IVES, E. F. KINGSBURY AND E. KARRER. *J. Franklin Inst.* 186, 401-38, 585-625 (1918).—Mantles of  $ThO_2$ ,  $ZrO_2$ ,  $MgO$ ,  $Al_2O_3$ ,  $SiO_2$ , and  $BeO$ , resp., were of such relatively low visible emissive power that each of these oxides by itself was useless for light-production and of no promise as a colorant. Study was also made of mantles composed of mixts. of  $ThO_2$

plus the oxide of *one* of the following metals: Ce, U, Mn, Ni, La, Pr, Ne, and Er. In all cases an optimum mixt. proportion was found; at this optimum, the luminous efficiency was greatest for Ce, followed by U and Ne, resp., and was too low in the case of the other oxides to be of much interest. "The comparatively high efficiency of both the Ce and U oxides is due to the presence of a strong absorption band in the blue end of the visible spectrum. In the case of ceria this band is present only when the oxide is hot; in the U oxide it is present also in the cold condition. Other oxides—namely, Mn and Pr—bleach when hot, thereby partly losing their visible absorption bands, with consequent low efficiency." Oxides of the following metals were not suitable for use as constituents of mantles: Ba, Cd, Ca, Fe, Mo, Sr, Ti, W, Zn, also Pt. The remainder of the paper is of interest to the physicist and the illuminating engineer.

JOSEPH S. HEPBURN.

**The use of niter cake in the manufacture of sulfate of ammonia.** P. PARRISH. *Gas J.* 143, 395-6(1918); cf. *C. A.* 11, 2728.—By adding ground niter cake to the acid charge pot, a satisfactory mixture of mixed sulfate of  $\text{NH}_4$  and Na containing a higher content than 10% of  $\text{Na}_2\text{SO}_4$  was obtained, as well as economy of working. The  $\text{H}_2\text{SO}_4$  content of the bath must not fall below 6% or else ferrocyanides may form. The free acid content of the saturator liquor should be detd. by titration. The niter cake should be added with regularity and should be of substantially uniform quality. The amount of undecomposed nitrate in the niter cake should also be known as this is the chief cause of the corrosion of the Pb. In one method the niter cake was dissolved in the feed acid in suitable Pb-lined tanks placed contiguous to the saturator at such a height that the niter-cake acid soln. flowed to the saturators by gravity. The Pb-work of the dissolving tank corroded so badly that the method was discontinued. This corrosion was due to the use of an inferior quality of niter cake or possibly the use of arsenical acid. A niter-cake soln. with an approx. content of 6%  $\text{H}_2\text{SO}_4$  can be fed to the saturator along with the acid in certain fixed proportions. The  $\text{NH}_3$  and the steam passing forward from the stills as in ordinary  $(\text{NH}_4)_2\text{SO}_4$  plants, or with the coke gas as in direct plants, enters the saturator where absorption occurs and the sp. gr. increases. After a time deposition of  $(\text{NH}_4)_2\text{SO}_4$  and  $\text{Na}_2\text{SO}_4$  occurs. Some of the saturator liquor is ejected into the mother-liquor well and the supply of acid and niter-cake soln. to the saturator is resumed until the normal level of the bath is restored. On reaching the mother-liquor well the discharged soln. cools and on reaching  $46^\circ$  practically all the  $\text{Na}_2\text{SO}_4$  crystallizes out. The lighter mother-liquor containing  $\text{NaHSO}_4$  and  $(\text{NH}_4)_2\text{HSO}_4$  is again pumped to the saturator and a definite cycle of operations established. A Mond recovery plant at Langworth, Eng., uses the following process: The gases leaving the producer after having been cooled and treated for the extn. of tar, etc., are scrubbed in a tower with a 3-4%  $\text{H}_2\text{SO}_4$  soln. On reaching the satn. point, the soln. is evapd. and treated to crystallize out the  $(\text{NH}_4)_2\text{SO}_4$ . The residual mother-liquor is concd. at about  $80^\circ$  and very little  $\text{Na}_2\text{SO}_4$  from the niter cake goes into soln. The mother liquor, containing additional  $\text{H}_2\text{SO}_4$ , with the niter-cake, is used in the tower, and the resulting  $\text{Na}_2\text{SO}_4$  sludge is washed free of  $\text{NH}_4\text{OH}$  with water, the washings being used to dil. the tower acid. By this process,  $(\text{NH}_4)_2\text{SO}_4$  with a content of 24.5%  $\text{NH}_3$  and 0.4%  $\text{H}_2\text{SO}_4$  is being produced and saleable Glaubers' salt can be crystallized out, containing only traces of  $\text{NH}_3$ , which appears to be occluded in the crystals of  $\text{Na}_2\text{SO}_4$ .

E. A. TSCHUDY.

**The composition of the light oil obtained in the benzene extraction at the Wester Gas Works in Amsterdam.** J. P. WIBAUT. *Het Gas* 38, 239-40(1918).—Analyses of light oil from benzene extns. showed the following variations of % compn.: 90%  $\text{C}_6\text{H}_6$ , 39.0 to 53.1; toluene fraction, 3.0 to 5.7; solvent naphtha, 5.1 to 12.3; tar oils, 23.2 to 33.0; loss by washing with alkali and dil. acid, 10.2 to 12.8. The rather high

% of tar oil is due to incomplete sepn. of the solvent used from the light oil. This tar oil contained large amts. of  $C_{10}H_8$ . The loss on washing consists chiefly of phenols and pyridine. The light oil contains from 1.7 to 2.4 g. of  $CS_2$  per l. J. F. SMITH.

**Determination of naphthalene in tars and tar oils.** KNUBLAUCH. *J. Gasbel.* 61, 134-7, 145-9(1918); *J. Soc. Chem. Ind.* 37, 458A(1918).—K.'s method of estg.  $C_{10}H_8$  by direct titration of the picrate with alkali (*C. A.* 11, 3198) has been adapted to the analysis of tars and tar oils. The pptn. is effected with both the sample and the picric acid in alc. soln. After mixing, the soln. is dild. with  $H_2O$ , and the pptn. is complete if the resulting soln. contains not more than 10% of alc. and at least 0.2% of picric acid or less than 12.5% of alc. and at least 0.3% of picric acid. The amt. of picric acid must be chosen to ensure these end concns. without the pptn. of free picric acid. *Crude naphthalene and tar oils:* To an amt. containing 0.1 to 0.2 g.  $C_{10}H_8$  in an erlenmeyer, add 15 cc. abs. alc. and picric acid equiv. to 2 to 2.5 times the wt. of  $C_{10}H_8$ ; heat to 60-5° until all is dissolved, cool, dil. to 120 cc. with a 0.3% aq. soln. of picric acid. Let stand 1 hr., collect the ppt. on a 10-cm. smooth filter, wash with a 0.2% picric acid soln., transfer paper and contents to a small beaker with 50-80 cc.  $H_2O$ , and titrate with 0.1 N NaOH soln., using Me-orange as indicator, and deducting 0.2 cc. for the picric acid retained by the paper and ppt. The results with pure  $C_{10}H_8$  were quant.; PhOH does not interfere. *Tar:* The amt. taken should contain about 0.07 g.  $C_{10}H_8$ , and the proportion of picric acid as above, but in no case more than 0.6 g. so as to avoid pptn. at the end. With viscous tars, weigh the sample into a small beaker and add the picric acid dissolved in 15 cc. of alc. After heating to 60-5°, carefully ext. the tar by stirring and manipulation with a glass rod for at least 30 mins. When cold, add 15 cc.  $H_2O$  and 120 cc. of 0.3% aq. picric acid soln.; leaving the tar residue in the beaker, transfer the picrate ppt. to a filter and continue the detn. as above. Tars containing much light oil and little  $C_{10}H_8$  give unsatisfactory end points, and in such cases decompose the picrate ppt. by an excess of 0.1 N NaOH soln., wash the liquid with hot  $H_2O$  into a small beaker, and filter into a conical flask. Add 5-6 cc. of a neutral soln. of an  $NH_4$  salt and det. the  $NH_3$  liberated by distn. into a measured vol. of 0.1 N  $H_2SO_4$ . When the filtration of the picrate is difficult, ext. the tar with 15 cc. of a soln. of picric acid in alc., pouring the ext. into a conical flask; make further extns. with 35 cc. of alc. and add the washings to the first, leaving the tarry residue behind. Remove 35 cc. of the alc by distn., and continue the detn. of the picrate as described. *Light oils or tar oils:* It is necessary to remove a portion of the light oil before pptn. Treat the oil taken with the picric acid dissolved in 25 cc. of alc. and distil off a portion of this; cool, add the 0.3% picric acid soln. so as to dil. the alc. 10 times, and complete the detn. by one of the methods described. The vol. of alc. distd. and the wt. of picric acid taken must be chosen so that the end concns. are appropriate.

F. W. SMITHER.

**Determination of albuminoid nitrogen in liquids containing gas liquor (STEPHENSON) 7.**

---

**Fuel-treating compositions.** J. W. EDMONDS. *Brit.* 116,252, Apr. 24, 1918. A compn. for use in treating fuel consists of NaCl,  $Na_2CO_3$ , whiting, gum acacia, and oxalic acid, with or without  $ZnSO_4$  or lamp black, or both. Suitable quantities of these ingredients are 100 lbs. of NaCl, 63 lbs.  $Na_2CO_3$ , 27 lbs. of whiting, 19 oz. of gum acacia, 15 lbs. of oxalic acid, 2 lbs. 2 oz.  $ZnSO_4$ , and lampblack sufficient to color the compn. In making the compn., the NaCl and lampblack are mixed together and dried, the  $Na_2CO_3$  is ground and mixed with the whiting, and the mixt. is dried. The 2 mixts. are mixed together, and the resulting mixt. is mixed successively with the

gum acacia,  $\text{ZnSO}_4$ , and oxalic acid. Mixed with hot  $\text{H}_2\text{O}$ , the compn. is sprinkled over the coal or other fuel.

**Filtering peat.** K. E. EDGEWORTH. Brit. 118,903, Sept. 24, 1917. Peat which has been heated to  $150^\circ$  is filtered under pressure, while hot, through unglazed porcelain or earthenware. The porcelain or earthenware is formed into cones, disks, or plates of more or less stellate section, a central passage being left for the escape of the  $\text{H}_2\text{O}$ , and the peat surrounding the filtering unit on all sides. To detach the peat from the filter, the pressure is suddenly released while the temp. is between  $105$  and  $130^\circ$ , whereupon the peat is disintegrated by the sudden production of steam.

**Carbonizing processes.** O. F. STAFFORD. Brit. 119,040, Sept. 10, 1918. Commi-nuted wood or saw dust is carbonized for the production of charcoal, etc., and of volatile by-products by means of a process in which previously dried wood is heated to a temp. appreciably above  $100^\circ$  but below  $250^\circ$ , and is then introduced into a retort which has been heated to above  $280^\circ$  but below a red heat, preferably near or above  $400^\circ$ . It is stated that the wood thus treated becomes carbonized and gives off by-products; the action is exothermic so that the process may be carried on substantially without the application of additional external heat by employing a sheet Fe or other retort provided with a thick layer of insulating material. The preheated sawdust, etc., is passed from a hopper by a conveyor to the retort opening, and the charcoal may be discharged as required through an outlet normally closed by a stopper actuated by a discharge lever. The temps. are noted by means of thermometers. An outlet for leading the vapors produced to condensers is provided. Instead of using the insulating cover, the retort may be supplied externally with a slight amt. of heat, sufficient to balance radiation losses, etc. The initial heating of the retort may be effected by burning wood in the retort.

**Destructive distillation.** BLAIR, CAMPBELL & McLEAN, J. K. ROSS and E. P. CORNER. Brit. 118,960, Dec. 13, 1917. A retort for the destructive distn. of sawdust, shavings, wood, peat, beans, nuts, and the like is constructed with a number of superposed trays formed with radial openings through which the material passes successively from the highest tray to the lowest and finally to the discharge conveyor, etc. The trays are formed with apertures through which the vapors pass, and the material on the trays is acted on by brushes, chains, rakes, etc., carried by rotating arms, these brushes, etc., being set at different heights, so that they agitate the charge as well as feed it forward to the apertures through which the charge falls to the tray below. The retort is heated by gas, etc., part of the gas produced by the retort being used if required. Alternatively, the trays may be rotated and the rotating arms fixed. Automatic feeding and discharging devices are employed, and the bottom of the retort is inclined.

**Methane.** E. E. DURT and P. C. DURT. Brit. 116,302, June 28, 1917.  $\text{CH}_4$  is prepared by heating a mixt. of C (coke, charcoal, or graphite) with a metallic hydroxide, and a catalyst, *vis.*, Ti, U, Cu, Ni, or their compds., to a high temp. Suitable metallic hydroxides are those of Na, K, Ba, Sr, Ca, Al, Fe, Mn, or Ti. The reaction of the metallic hydroxide on C yields  $\text{CO}$  or  $\text{CO}_2$  and H which, in the presence of the catalyst, react to form  $\text{CH}_4$  and  $\text{H}_2\text{O}$ , the latter reacting with more C. Cf. 29,624, 1913 (C. A. 9, 2448).

**Washing gases.** J. A. SPENCER. Brit. 116,319, Nov. 24, 1917. A gas scrubber for removing  $\text{NH}_3$ , naphthalene, and other impurities from coal gas, of the kind in which the gas is passed into contact with rotating wheels which dip into tanks and are formed of sections composed of bars or laths secured to segmental bands or metal sheets held in position by transverse bolts, is constructed with a number of rods, dowels, or tubes,

preferably arranged so as to break joint, secured between segmental plates on boards formed with apertures for receiving the rods, and attached in a contiguous manner by means of bolts and nuts to similar plates which are secured together by transverse bolts and nuts. The plates last mentioned are secured to the rotating wheel by transverse bolts which pass through slots in the plates.

**Coking processes.** H. K. HILLER. Brit. 118,522, Nov. 20, 1917. A gas suitable for use in containers or motor vehicles, etc., and consisting mainly of  $\text{CH}_4$ , is obtained by distg. at a temp. not exceeding  $500^\circ$ , bastard cannel coal, lignite, wood, peat, shale, etc., in an horizontal or vertical retort, through which the material is continuously fed in a thin layer or column by means of a screw conveyor or the like. Cracking or dissociation of the gaseous products is prevented by introducing into the retort part of the gas which is the result of the process and which is compressed to a pressure of at least 15 atm. and allowed to expand into the retort to cool and carry away the gaseous products produced. These are then passed through condensers for extg. liquid hydrocarbons, and other hydrocarbons are extd. by passage through washing oils. The gas is then compressed by a water-cooled pump to a pressure of 15 atm., whereby a *spirit similar to gasoline* is formed, and a stable gas is left which is mainly  $\text{CH}_4$ , part of the gas being used to carry out the process described above.

---

## 22. PETROLEUM, ASPHALT AND WOOD PRODUCTS.

---

F. M. ROGERS.

Coking processes (motor fuel) (Brit. pat. 118,522) 21. Purifying oils (Brit. pat. 118,353) 27.

---

**Cracking hydrocarbons.** S. MAXIM and A. W. CROSSE. Brit. 118,122, Aug. 18, 1916. Heavy hydrocarbons, such as kerosene, are converted into lighter hydrocarbons by subjecting them while under pressure and at a high temp. to agitation and electrochem. action. A suitable app. is specified.

**Cracking hydrocarbon oils.** J. NELSON. Brit. 116,304, Mar. 13, 1917. Hydrocarbon oils and the like are cracked by passing the hydrocarbon or its vapors through an agitated liquid contact material such as molten Pb, the agitation of the liquid being effected preferably by the passage of the hydrocarbon vapors and gases through it. If the hydrocarbons to be cracked contain tarry or other non-volatile matters, they may be distd. from an auxiliary vessel and the distillate or vapors subjected to the cracking process. The whole or part of the product may be subjected to one or more re-treatments. The app. may consist of one or more vertical cylinders set in a furnace and each contg. a quantity of molten Pb in which is immersed the lower end of a vertically adjustable oil-inlet pipe, the products passing out through a lateral pipe. Modifications are specified.

**Refining oils.** H. G. C. FAIRWEATHER. Brit. 116,418, Sept. 4, 1917. In a process of refining lubricating oils to produce paraffinum liquidum, the oils, after treatment with acid and the removal of the sludge formed thereby, are mixed with  $\text{NH}_3$  and alc. and the mass is allowed to settle. In one example of the process,  $\text{H}_2\text{SO}_4$  is added, in successive instalments of increasing strength, to an approx. equal wt. of oil, the sludge being removed after each treatment. A soln. contg. 1 vol. of strong  $\text{NH}_4\text{OH}$  to 2 vols. of strong alc. is then added, and the resulting product, after settling, is dried by passing a current of hot air through it or otherwise, and is filtered through a column of fuller's earth.

## 23. CELLULOSE AND PAPER.

A. D. LITTLE.

**Cellulose articles.** C. F. CROSS and VISCOSE DEVELOPMENT CO. Brit. 116,366, June 12, 1917. In the manuf. of coverings or masses from amorphous cellulose regenerated from the xanthate, the covering or mass is subjected to a progressively increasing continuous or intermittent rolling pressure during drying. The method may be applied to the covering of shafts, spindles, rollers, or wheels with a layer of cellulose. A tube or annulus of the hydrated regenerated cellulose is formed, cut up into suitable rings, etc., washed, and placed on the roller, etc., to be covered; the shrinkage which occurs on drying fixes the covering on, and gradually increasing rolling pressure is then applied during the subsequent drying; the drying may be accelerated by heating the rolling surfaces or by a current of hot air. Glycerol or other material may be incorporated with the cellulose at a suitable stage in the process. Rollers made or coated with cellulose in this way may be engraved and used for printing purposes. According to the provisional specification, "top rollers" of cotton-spinning machines may be made in this way. Cf. 2,880, 1905.

**Wood cellulose, etc.** AKTIEBOLAGET CELLULOSA. Brit. 116,288, May 27, 1918. In obtaining cellulose by boiling raw material such as wood with NaOH lye, the lye is subjected during the boiling to a "contact substance" having a reducing action, such as Hg. The boiler is given a thin coating of Hg once every 14 days, by filling it with 0.001 normal  $\text{HgCl}_2$  soln. The lye used, which must be free from S, contains about 60 g. of  $\text{Na}_2\text{O}$  per liter and its strength is maintained by adding lye during the boiling operation. The temp. is  $140-70^\circ$  and additional pressure may be obtained by means of compressed air. The lye may be obtained by dissolving soda from the dry distn. of waste liquor in the waste lye from a previous boiling after it has been freed from lignin by  $\text{CO}_2$ . Air may be removed from the material to be treated by drenching it with  $\text{H}_2\text{O}$  or by exhausting the boiler before admitting the lye. The used lye may be regenerated by the process described in 6,652, 1912 (C. A. 7, 3025).

**Non-inflammable celluloid.** H. DREYFUS. Brit. 118,891, Sept. 14, 1917. In the manuf. of non-inflammable celluloid, including, in particular, those having a basis of acetate of cellulose, the pressure to which the celluloid is subjected for some hrs. to complete the production is about 300 kg. per sq. cm. or upwards.

**Celluloid-like material from vegetable proteins.** S. SAROW. U. S. 1,280,862, Oct. 8. Vegetable proteins such as those from peas, beans, wheat or corn are partially hydrolyzed (*e. g.*, by the action of steam, dil. acids or alkalies, enzymes,  $\text{SO}_2$  or alc.) and a mixt. for making molded articles is then prep'd. from this partially hydrolyzed material by combining it with glutinizing and condensing agents such as tannin,  $(\text{CH}_3)_3\text{N}_4$ , trioxymethylene, aldehydes, NaOH, sulfides, borates, silicates, carbonates, phosphates, sulfites, formates or acetates of alkali metals or of  $\text{NH}_4$ , or with  $\text{H}_3\text{PO}_4$  or other inorganic acids, organic acids, phenol, nitroresol or other modifying ingredients.

**Plastic material containing ethyl cellulose ether.** P. C. SEEL. U. S. 1,281,080, Oct. 8. A mixt. suitable for making smooth, flexible, transparent films, or for forming molded articles, is made from ethyl cellulose ether 50-100, combined with chlorinated naphthalene derivs. 10-20,  $\text{CHCl}_3$  200-400 and denatured alc. 150-250 parts. Amyl acetate and chlorinated anthracene derivs. also may be used in similar compns. The products are resistant to photographic chemicals and are suitable for the manuf. of motion picture films.

**Cellulose acetate.** H. DREYFUS. U. S. 1,280,974, Oct. 8. An acetylizing mixt. is formed of  $\text{Ac}_2\text{O}$  300, glacial HOAc 400 and  $\text{H}_2\text{SO}_4$  15-18 parts and there is then

added to this mixt. sufficient  $\text{Na}_2\text{CO}_3$  or  $\text{NaOAc}$  to convert most but not all of the  $\text{H}_2\text{SO}_4$  into bisulfate. Cellulose containing 3-6%  $\text{H}_2\text{O}$  is then treated with the soln. thus formed and afterward the cellulose acetate produced is subjected to the action of the acetylizing soln. after 5-50% of  $\text{H}_2\text{O}$  has been added, until a product is obtained which is insol. in  $\text{CHCl}_3$  alone but sol. in  $\text{CHCl}_3$  mixed with alc. and somewhat sol. in acetone. U. S., 1,280,975 relates to making a cellulose acetate insol. in  $\text{CHCl}_3$  and also insol. in  $\text{CHCl}_3$ -alc. mixt., by reacting on cellulose with a mixt. of  $\text{Ac}_2\text{O}$  300, glacial  $\text{HOAc}$  400 and  $\text{H}_2\text{SO}_4$  15-18 parts. Before the soln. is used, it is cooled to below  $0^\circ$  and during the acetylation the temp. is maintained below  $25^\circ$  until after a product is formed having the desired solubilities.  $\text{H}_2\text{O}$  may be added to the reaction products, to change the solubilities of the acetate formed.

**Viscose.** B. BORZYKOWSKI. Brit. 116,268, Apr. 15, 1918. Threads and other articles are prep'd. from viscose soln. in a fresh or only slightly matured and unpurified condition. As pptg. baths, dil. acids (contg., *e. g.*, less than 5%  $\text{H}_2\text{SO}_4$ ) or strong salt solns. of d. greater than  $18^\circ \text{Bé.}$  may be used and the threads are given an extended travel (at least 10 cm.) through the bath. Acids, up to 10% of  $\text{H}_2\text{SO}_4$  or acid salts such as  $\text{Al}_2(\text{SO}_4)_3$  may be added to the salt solns. Alcs., metallic salts, or organic substances such as the nitroso bases referred to in U. S. 1,143,569 (*C. A.* 9, 2315) for preventing deposition of S on the threads, may be added to the pptg. baths. In examples, clear threads are formed by pptg. in a 2.5-3%  $\text{H}_2\text{SO}_4$  bath, with a distance for pptn. of 25-30 cm. and a take-up speed of 40 m. per min., and artificial silk is made by pptg. in a soln. of Na and  $\text{NH}_4$  sulfates of a d. of at least  $22^\circ \text{Bé.}$ , contg. 2-3% of  $\text{HCl}$  or  $\text{H}_2\text{SO}_4$ , and at a temp. of  $35\text{-}50^\circ$ .

**Drying paper.** E. PARTINGTON DOVERDALE. Brit. 118,511, Nov. 3, 1917. In drying paper in a paper machine, a proportion of the drying cylinders over which the paper first passes is heated to, and maintained at, a temp. higher than the temp. of the remaining cylinders, which may be maintained at a const. lower temp. or at a progressively decreasing temp. In an example, where 16 drying cylinders are used, the first 5 are heated to  $200^\circ \text{F.}$ , and thereafter there is a successive fall of  $10^\circ \text{F.}$  per cylinder.

**Paper tubes.** F. WOOLFENDEN. Brit. 118,169, Sept. 12, 1917. In the manuf. of paper tubes or bobbins, such as are used in textile industries, the paper is coated with glue while being wound, and the tube so produced is similarly coated, and then subjected to the action of  $\text{HCHO}$  soln. or vapor and dried at a temp. of  $220^\circ \text{F.}$

C. E. MUNROE.

**Methods for routine work in the explosives physical laboratory of the Bureau of Mines.** S. P. HOWELL AND J. E. TIFFANY. Bur. Mines, *Tech. Paper* 186, 63 pp. (1918).—States character of materials tested; the organization of the section for the work, with the duties of each person; the precautions to be observed in storing, handling and testing; the quantities required; the methods of receiving, identifying and recording samples sent and of recording the results of the tests; detailed descriptions of the methods of making the several tests and computing the results. There are appended 15 tables for use in the computations, many of which have been constructed at the Pittsburgh Testing Station.

CHARLES E. MUNROE.

**The determination in cotton for nitration of the matter which is insoluble in sulfuric acid.** ED. JUSTIN-MUELLER. *l'Ind. chim.* 5, 218-20(1918).—Cellulose is practically completely sol. in properly dild.  $\text{H}_2\text{SO}_4$  or ammoniacal  $\text{CuO}$  while the non-cellulosic

matter present, and particularly the cuticle, or epidermis, is not dissolved but is carbonized and remains with the insol. mineral compds. which are detd. as "ash." These consist largely of  $\text{Ca}_3(\text{PO}_4)_2$  and  $\text{CaCO}_3$  and an error may creep into this detn. through the action of the  $\text{H}_2\text{SO}_4$  converting them into sulfates, for, as shown, these mineral compds., which amount to 25% of the wt. of insolubles in a cotton of good quality, are increased to 32.59% by the  $\text{H}_2\text{SO}_4$  treatment. Mueller describes the method of calcn. to be followed through which to avoid this error. CHARLES E. MUNROE.

Apparatus for drowning, washing and conveying nitro-cellulose. J. D. ELACK. U. S. 1,280,981, Oct. 8.

## 25. DYES AND TEXTILE CHEMISTRY.

L. A. OLNEY.

Analysis of logwood extracts. G. SAVINI. Rome. *Ann. chim. applicata* 10, 26-32(1917).—Present war conditions have given increased value to vegetable coloring exts., among which the principal one is logwood ext. Its analysis comprizes detns. of  $\text{H}_2\text{O}$ , ash, coloring and non-coloring substances, insol. substances, and tinctorial power. It must also be examnd. for presence of adulterants, *e. g.*, glue, dextrin, tanning exts., molasses, etc. Molasses is chiefly used as adulterant. For detn. of  $\text{H}_2\text{O}$ , take 5 g. of the material, dry in an oven for 6 hrs. at  $105^\circ$  in a Pt dish of 10 cm. diam. For detn. of ash use the residue from the  $\text{H}_2\text{O}$  detn. To avoid the enormous swelling that usually accompanies the beginning of carbonization, S. recommends the following: Put the dish with residue from  $\text{H}_2\text{O}$  detn. in the oven for 1 hr. at  $105^\circ$ , then gradually raise the temp. to  $170-80^\circ$ , after which carbonize directly over the flame. Introduce the dish into the muffle, regulating the temp. so as to avoid fusion of the ash, especially with exts. adulterated with molasses. The detn. of the sugars offers some difficulty because the solns. obtained through the use of basic Pb acetate in defecation, and also Na sulfate and phosphate, assume rapidly in the light a more or less intense blue color that renders the reading of the saccharimeter impossible. S. recommends the following method: Dissolve 40 g. of the fluid ext. or 20 g. of dry ext. in about 100 cc. boiling  $\text{H}_2\text{O}$ . Pour the whole into a tared flask of 200-300 cc. Add to the hot liquid while agitating, not less than 50 cc. Pb acetate. Cool rapidly, bring to vol. of 200 cc. then add 15-20 cc.  $\text{H}_2\text{O}$  to allow for the vol. of insol. substances (20 cc. for exts. containing less than 10% sugar, 15 cc. for exts. containing over 10% sugar). Shake, filter rapidly, pour 100 cc. of the filtrate into a 150-cc. flask, add a concd. soln. of Na sulfate and phosphate to complete pptn. of Pb. Bring to vol. and filter. The liquid thus obtained is treated in the ordinary manner, inverting a part and detg. the sucrose by Clerget's method, and finally the reducing sugars by the chem. method. In this manner there are obtained limpid and colorless liquids which remain so for a considerable time, and the detns. are exact. Defecation with hydrated Fe oxide proposed by Cochenhausen is not practically possible for saccharimetric detns. The presence of molasses may be indicated from some physico-organic character. If a little of the ext. is heated in a dish with boiling  $\text{H}_2\text{O}$ , the characteristic odor of molasses may be perceived in presence of the latter in amounts even as small as 5%. In dry exts. the presence of considerable quantities of molasses causes a change of color and a pitchy consistency. Pure exts. have a decidedly reddish brown color, are friable and do not soften except at high temps. Exts. containing much molasses take on a clear brown color and soften even between the fingers; in time, even at ordinary temps., especially in warm weather, they become fluid and take the shape of the containing vessel. According to Cochenhausen the brown color of the ash of the ext. often indicates the presence of molasses.

S. found, however, that with exts. containing as high as 20% molasses, the ash was fairly white. A good indication of the presence of molasses is furnished by the easy fusibility of the ash of exts. containing it, on account of their high content in K salts. The above crude tests are qual. only. S. worked out a method of detg. molasses, based on the fact of the small amount of  $K_2CO_3$  in logwood ext.: the ash amounts to about 2%, of which  $\frac{1}{4}$  is  $K_2CO_3$ . The method is as follows: Lixivate with boiling  $H_2O$  the ash obtained in detn. of mineral substances. Filter through a small filter, wash the dish and filter well so as to use not more than 100 cc., cool, titrate with 0.1 N  $H_2SO_4$ , using Me orange as indicator. Express the results as cc. 0.1 N alk. per 100 g. dry ext., which from may be calcd. the corresponding amount of  $K_2CO_3$ . The method gives satisfactory results. In only 1 sample of fluid ext. was there wide divergence between volumetric and gravimetric figures; this was due to adulteration with tanning ext., and consequent presence of much  $H_2SO_4$ . Taking 0.4-0.5% as being the amount of  $K_2CO_3$  in pure logwood ext., and 6-7% as that of molasses, the estn. of the amount of the latter in logwood ext. may be made. This estn. should be checked by the amount of sucrose found, assuming that molasses contains an average of 50% sucrose. If a certain quantity of sucrose is found in a sample of ext. and the amount of  $K_2CO_3$  is equal to that of the pure ext., then it is evident that sugar has been added as such (may be raw sugar), and molasses is not present. Analyses of 14 different samples of dry and liquid com. logwood exts. are given.

ROBERT S. POSMONTIER.

**Present position and future prospects of the natural indigo industry.** W. A. DAVIS. *Agr. J. India* 13, 441-59(1918); cf. *C. A.* 12, 1125, 2444.—One of a series of papers dealing with the improvements of the agricultural production of indigo. If the yield of green plants can be brought up to 4.5 tons per acre it is shown that the natural dye should be able to compete favorably with the synthetic article. The production of indigo grown in soils without fertilization has decreased from year to year. The production has been increased by phosphate fertilization. The soils have undergone considerable deterioration as regards the amount of  $P_2O_5$  present during the last 20 years. The wilt of the indigo plant is held to be caused by a lack of P in the soil. The first symptom of deterioration in the soil is the gradual failure of seed yield, which is said to be the first indication of phosphate starvation. The amt. of indigo in the plant has decreased with the yield. Phosphate fertilization is urged upon the growers.

J. J. SKINNER.

**Black dyes. I. Natural coloring matters.** CHAS. S. WEHRLY. *Color Trade J.* 2, 118-20(1918).—General discussion of logwood, its chem. compn., methods of dyeing, properties, and economic consideration. **II. Black sulfide dyes.** *Ibid* 154-6.—A general discussion of their compn., use, application and methods of detecting on the fiber. **III. Chrome blacks.** *Ibid* 189-92.—General discussion of their constitution, preparation, uses and application. **IV. Developed colors.** *Ibid* 208-12.—A general discussion of their constitution, prepn., uses and application. The various developers used are also discussed in some detail.

L. A. OLNEY.

**Hematoxylon africanum.** A. G. PERKIN. *J. Soc. Dyers Colourists* 34, 99(1918).—Hitherto the genus *Hematoxylon* has been represented only by the *H. campeachianum*, but another species termed the *H. africanum* has been recently discovered in So. Africa. *H. africanum* differs from logwood in that the coloring matter it contains is not hematoxylon but a substance which resembles brazilin in its general properties. It is not as good a dye as brazilin and is of no technical importance.

L. A. OLNEY.

**Intermediate products and dyes.** J. C. CAIN. *J. Soc. Dyers Colourists* 34, 200-1(1918); *British Sci. Products Exhibition Catalogue* p. 11.—At the outbreak of the war it was discovered that the apparently wide range of dyes made in England had been

produced largely from intermediates made in Germany. Fortunately England was a great producer of the raw materials, and although handicapped by the necessity of diverting chemical resources to the production of munitions she has risen to the occasion, and is today producing the intermediates necessary for the manuf. of most of the essential dyes. It will, however, be some time before the wide range of colors covered by the Germans will be manufd. L. A. OLNEY.

**British dye industry.** M. O. FOSTER. *J. Soc. Dyers Colourists* 34, 201(1918).—In discussing the decay and renaissance of British dye making, F. points out that great effort will be needed to overtake Germany. It can only be achieved if money is spent on experimental work. L. A. OLNEY.

**Dyes and intermediate products.** SOCIÉTÉ L'AIR LIQUIDE (SOC. ANON. POUR L'ÉTUDE ET L'EXPLOITATION DES PROCÉDÉS G. CLAUDE). *Brit.* 118,103, July 22, 1918. 4'-*p*-Hydroxyphenylamino-2-amino-4,5-dichlorodiphenylamine is prepd. by condensing 1-nitro-2,4,5-trichlorobenzene with aniline in the presence of NaOAc, condensing the resulting dichloronitrodiphenylamine with *p*-nitrosophenol in H<sub>2</sub>SO<sub>4</sub> soln., and reducing the product. A dye, giving navy blue shades on cotton in alkali sulfide or hyposulfite baths, is obtained by heating 4'-*p*-hydroxyphenylamino-2-amino-4,5-dichlorodiphenylamine with S or a polysulfide, alone or in the presence of a solvent such as glycerol, bases, phenols, etc.

**Dyes; intermediate products.** SOC. ANON. POUR L'IND. CHIM. À BÂLE. *Brit.* 118,448, Aug. 28, 1917. Pyrazolone-azo dyes are obtained (1) by coupling the diazo compds. of anthranilic acid or its substitution products (except those contg. OH in *o*-position to the NH<sub>2</sub> group) with pyrazolones of the benzene or naphthalene series contg. an OH group in the aryl residue and derived from acetoacetic ester, or (2) by coupling the diazo compds. of amines (not contg. OH or COOH in *o*-position to the amino group) with pyrazolones derived from acetoacetic ester and contg. an OH and a COOH group in the aryl residue. Examples are given. The pyrazolones mentioned above are made from the corresponding hydrazines and acetoacetic ester. Cf. 3,373, 1908, 13,843, 1914 (*C. A.* 9, 3367), 12,250, 1915 (*C. A.* 11, 302), and 13,204, 1915 (*C. A.* 11, 542).

**Dyes; pigments.** W. A. ALLSEBROOK. *Brit.* 118,735, Nov. 7, 1918. A sol. coloring matter similar to Vandyke brown is prepd. by grinding powdered waste leather with a warm strong soln. of caustic alkali until the product is dry and water-sol.; if the waste leather contains cellulose as impurity, a small amt. of an alk. oxidizing agent is added to the mass, *e. g.*, NaOCl or Na<sub>2</sub>O<sub>2</sub>. Insol. pigments are obtained by grinding an aq. soln. of the color with Al<sub>2</sub>(SO<sub>4</sub>)<sub>3</sub> soln. and a substratum such as SiO<sub>2</sub>, washing the product, and drying, or by grinding the soln. with CaSO<sub>4</sub>.

**Dyeing.** IMPERIAL TRUST FOR THE ENCOURAGEMENT OF SCIENTIFIC AND INDUSTRIAL RESEARCH and G. G. HEPBURN. *Brit.* 116,360, Jan. 11, 1917. Solns. which probably contain the diazo oxides RN<sub>2</sub>OC<sub>10</sub>H<sub>6</sub>SO<sub>3</sub>Na are obtained by treating with caustic alkalies or with salts of alk. reaction the diazosulfonates prepd. from diazo salts and 2-naphthol-1-sulfonates as described in 11,757, 1895. Insol. azo dyes are prepd. on the fiber by padding or printing with a soln. (suitably thickened if necessary) of the diazo oxides described above, and developing by ageing or by passing through an acid bath, or by exposure to an acid atm., *e. g.*, one contg. HOAc or HCCOOH. Or the diazo oxide soln. may be printed on material which has been prepd. with a salt of acid reaction or an org. acid, *e. g.*, Al<sub>2</sub>(SO<sub>4</sub>)<sub>3</sub>, tartaric or citric acid, and then dried. Examples are given of the production of *p*-nitroaniline red. The diazo or tetrazo compds. derived from  $\alpha$ -naphthylamine, nitro-*o*-toluidine, nitro-*o*-anisidine, benzidine, tolidine, and dianisidine also are mentioned as parent materials.

**Azo dye.** E. F. EHRHARDT and H. W. EHRHARDT. U. S. 1,281,243, Oct. 8. An azo dye is produced by combining diazotized picramic acid with the effluent from the fractional combination of diazotized picramic acid with a mixt. of cresols, stirring until combination is complete, then filtering and stirring with sufficient  $H_2O$  to form a paste. The dye so obtained dyes unmordanted wool from an acid bath chocolate-brown shades and dyes wool mordanted with Cr compds. olive-brown shades fast to scouring, milling and light.

**Dyes of the anthracene series.** R. BOHN. U. S. 1,280,648, Oct. 8. Dyes are produced by reacting upon an aromatic amine with an anthraquinone- $\beta$ -arylide, which may be substituted in the anthraquinone residue or in the arylamine residue or in both, in the presence of a caustic alkali or alkali metal alcoholate, and preferably also in the presence of an oxidizing agent. In some instances, the process of producing the dye and the production of the anthraquinone- $\beta$ -arylide can be effected in a single operation by heating the compds. which form  $\beta$ -arylinoanthraquinone (e. g., an anthraquinone- $\beta$ -sulfonic acid or a deriv. thereof and an aromatic amino compd., or a  $\beta$ -haloanthraquinone and an aromatic amine) in the presence of strong alkali and, preferably, in the presence of an oxidizing agent. Examples are given in which the dyes are formed: (a) by heating aniline, KOH and  $\beta$ -anilinoanthraquinone to  $180^\circ$ , blowing air through the mixt. and purifying the product by further blowing with air after addition of  $H_2O$ , followed by treatment with HCl to remove excess aniline, (b) by heating anhydrous aniline, NaOH, KOH and Na anthraquinone-2-sulfonate at  $180^\circ$  for 8 hrs. while passing air through the mixt., and purifying by extg. with a dil. alkali and with cold acetone. ( $\beta$ -Chloroanthraquinone may replace the sulfonate as starting material in this process, in which case a Cu compd. is preferably added to promote the reaction); (c) by treating the condensation product formed from  $\beta$ -anilinoanthraquinone and aniline with fuming  $H_2SO_4$  containing 23% of free  $SO_3$ , stirring for 22 hrs. at a temp. of  $80^\circ$ , then pouring the melt into cold  $H_2O$ , treating it for a short time with a soln. of  $FeSO_4$  and then pptg. the dye formed, by the addition of NaCl; (d) by treating the condensation product formed as described under "a" or "b" with  $H_3BO_3$  free from  $H_2O$ , and heating this mixt. with fuming  $H_2SO_4$  (containing 23% free  $SO_3$ ) for about 50 hrs. at  $90^\circ$ . The dyes formed are greenish or bluish powders. If unsulfonated, they are insol. in  $H_2O$ , aqueous acids and alkalis and sol. in org. solvents, but if they are combined with at least one  $HSO_3$  group they are sol. in  $H_2O$ , aq. acids and alkalis and in alc. and acetone. The unsulfonated dyes can be used in the production of colored varnishes containing oil or alc. The sulfonated dyes dye wool fast greenish or bluish shades.

## 26. PAINTS, VARNISHES AND RESINS.

A. H. SABIN.

**Injurious substitutes for turpentine in the painting trade.** ANON. *Am. J. Pub. Health* 8, 736.—"All paint of low b. p. distd. products of petroleum, light coal tar, turpentine,  $CS_2$ , or similar substances, shall be considered as injurious to health."

M. K. BIXBY.

**The Chinese wood oil tree.** E. N. WARD. *Agr. Gaz. N. S. Wales* 29, Pt. 6, 437 (1918).—An article calling attention to the ease with which this valuable tree can be induced to grow in N. S. Wales. The oil obtained from it is a valuable substitute for linseed oil. The seed contains about 58% of the oil.

R. B. DEEMER.

**The present condition of lac cultivation in the plains of India.** C. S. MISRA. *Agr. J. India* 13, 405-15 (1918).—Lac is a resinous secretion produced by a scale insect which sucks the juice of plants. In India the lac insect flourishes best on the *Acacia*

*arabica*: most of the supply is obtained from this source. From 1905 to 1916 over 450 million lbs. of shellac made from insect excretion was exported from Calcutta.

J. J. SKINNER.

**Constituents of resins. I. Siarsesinol from Siamese gum benzoin.** ALOIS ZINKE AND HANS LIEB. *Monatsh.* 39, 95-105 (1918); *J. Chem. Soc.* 114, I, 398-9.—Siarsesinol from Siamese gum benzoin is probably identical with the benzoresinol obtained by Ludy from the same source; it gives an *addition compound* with *acetic acid*,  $C_{30}H_{48}O_4 \cdot C_2H_4O_2$ , needles, m. 280-1.5°, and a *benzoyl derivative*, needles, m. 182-3°,  $[\alpha]_D^{20}$  30.0° (EtOH), which on hydrolysis regenerates siarsesinol. C. J. WEST.

**Estimation of cobalt (JONES) 7.** Washing coal, ores, etc. (Brit. pat. 119,038) 18. Titanium products; pigments (Brit. pat. 116,266) 18.

**Theatrical grease paints.** E. W. WILLCOCKS. Brit. 118,435, Aug. 24, 1917. Grease paints consist of a mixt. of a fatty base, such as hard and soft white paraffins, with a pigment prepd. by treating an insol. white powder with a soln. of a coloring matter which is insol. in the fatty base and then drying and repowdering the product. Specified insol. powders are starch, chalk, kaolin, ZnO, and mixts. thereof. Specified aniline dyes for use as the coloring matter are victoria scarlet, methylene blue, and auramine. Various tints may be prepd. by mixing the dye solns. or the dyed powders, with or without the addition of a black dye or powder. The proportion of dye to white powder may be varied but the proportion of the powder to the fatty base is standardized.

**Oil pastes.** C. R. ROGERS. Brit. 118,289, Aug. 14, 1918. Pptd. pigments such as white lead are ground up with oil without drying them. When the ppt. and oil are well mixed, a small quantity of borax or other weakly alk. salt is sprinkled on the mass and the milling is continued. The H<sub>2</sub>O contained in the moist ppt. seps. from the paste and is poured off.

**Fatty acids of linseed oil.** BARRY, OSTLER & SHEPHERD and J. BARRY. Brit. 118,228, Feb. 5, 1918. Linseed oil fatty acids are rendered suitable for use in the *linoleum, floor cloth, paint, color, etc.*, industries by treatment with superheated steam. Steam of about 400° is blown through the fatty acids in a steam-jacketed pan for about 18 hrs. By this means, metallic compds. are broken up, deleterious volatile substances are driven off, and the fatty acids are rendered more easily oxidizable. The product may be "smacked" or otherwise treated in the same manner as linseed oil for the manuf. of linoleum, etc.; a higher temp. than usual may be employed.

**Enamelled metal articles.** K. WARGE. Brit. 116,361, June 11, 1917. A vitreous enamel is applied to a sheet of Al or Al-contg. metal and the article is subsequently shaped from the enameled sheet by bending, stamping, etc. Suitable enamels consist of mixts. of SiO<sub>2</sub>, Na<sub>2</sub>B<sub>4</sub>O<sub>7</sub>, and red lead, or SiO<sub>2</sub>, red lead, and oxide of Bi. The enamel may be applied mixed with varnish, etc., or may be sprinkled upon a varnish layer or upon the heated material. Pigments may be added and filling such as metal or metal salts may be mingled with the enamel.

**Waterproofing fibrous materials.** P. F. BOVARD. U. S. 1,280,954, Oct. 8. Animal, vegetable or mineral fibrous material to be waterproofed is immersed in a saponified linseed oil and casein bath until the fibers are thoroughly satd., removed from the soln. and squeezed to remove excess soln., then treated with a soln. of Al acetate or other Al compd., and dried.

**Composition for removing paint.** L. HABER. U. S. 1,281,156, Oct. 8. A mixt. for removing paint is formed of paraffin 8, alc. 14, H<sub>2</sub>O 20, sal-soda 30 and C<sub>6</sub>H<sub>6</sub> 28 parts.

**Plastic mixtures of phenolic condensation products and solvents.** J. W. AYLSWORTH. U. S. reissue 14,530-1, Oct. 8. See original pat. 1,087,422, C. A. 8, 1354.

**Paints; varnishes.** F. W. SPERR and M. DARRIN. Brit. 118,079, Dec. 14, 1917. A paint or varnish comprizes a bituminous pitch, a volatile solvent such as solvent naphtha, and compds. or polymerization products of the coumarone-indene group (coumarone, indene, mono-, di-, or trimethylcoumarones, hydrindene, dicyclopentadiene, or styrolene). The coumarone-indene compd. may be dissolved in the solvent and added to the molten pitch. When polymerization products are used, the step of polymerizing may occur previously to, simultaneously with, or subsequently to the step of mixing the pitch and the soln. The coumarone-indene compd. in the mixt. may be polymerized by blowing through air or steam, or by the use of a catalyzer such as  $\text{AlCl}_3$ . Other materials, such as turpentine, linseed oil, Chinese wood oil, Venetian red, red lead, Zn oleate, Mn resinate, or  $\text{BaSO}_4$  may be added for use as thinners, driers, fillers, etc.

**Varnish from vegetable proteins.** S. SAROW. U. S. 1,280,861, Oct. 8. A varnish which contains  $\text{H}_2\text{O}$  as principal solvent and which does not change the natural color of wood to which it is applied is formed from proteins such as those obtained from beans, peas, wheat or corn mixed with a "glutinizing agent" and preferably also with a small amt. of a disinfectant such as phenol, creosote or salicylic acid and a dil. soln. of  $\text{CH}_2\text{O}$  in such small amt. as not to have any active condensing action. Among the glutinizing agents which may be used are:  $\text{NaOH}$ ,  $\text{KOH}$ ,  $\text{K}_2\text{CO}_3$ ,  $(\text{NH}_4)_2\text{CO}_3$ ,  $\text{Ca}(\text{OH})_2$ , borax, Na phosphate, urea, pyridine, glycine, formic, acetic, propionic, phenylpropionic, malonic, lactic, tartaric and malic acids, phenol, salicylic, benzoic, phosphoric and sulfurous acids. The varnish dries to a hard film which can be polished. It may be combined with pigments if desired.

## 27. FATS, FATTY OILS AND SOAPS.

R. SCHERUBEL.

**Fatty oils of *Sambucus racemosa*, L. II.** J. ZELNER. *Monatsh.* 39, 87-94 (1918); *J. Soc. Chem. Ind.* 37, 519A.—The European elder, *Sambucus racemosa* L. and the N. A. *Sambucus racemosa*, var. *arborescens*, although very similar, exhibit distinct but slight differences in nature. This probably accounts for the difference between the characteristics of the oil from the flesh of the red berries of these varieties. The oil from the former when kept for 15 years in a stoppered flask undergoes marked alteration with increase in the proportions of free acid and decrease in the I value. The elder seeds also yield an oil, sp. gr. 0.934 at  $15^\circ$ ,  $[\alpha]_D^{20}$  1.485, sapon. no. 190.8, and I value (Hübl) 162.0; in its drying properties and other characteristics this oil resembles linseed oil.

C. J. WEST.

Table of the more important tests and properties of official fats and oils (FLEISSIG)  
17.

**Recovering fats.** NATIONAL SANITARY SERVICE CO. Brit. 116,384, July 3, 1917. Fat is recovered from waste liquids, such as slaughter-house refuse liquid, by first pptg. the heavy sediment and then passing the liquid thus freed through a tank of known construction wherein a relatively large still body of liquid is maintained above an underlying accelerating current of the same, the fat sepg. in the still area and the waste being drawn off below.

**Recovering fats from waste water.** G. G. JARMAN. Brit. 118,332, Aug. 25, 1917. In a process of sepg. by a centrifugal machine grease from  $\text{H}_2\text{O}$  in which wool

has been washed, the  $H_2O$ , preferably heated nearly to boiling, is passed through a centrifugal filtering device to sep. the sand and like impurities, and then through a bowl centrifugal to sep. the grease from the  $H_2O$ . A suitable app. is specified.

**Purifying oils.** SWAN PROCESS OIL CO. Brit. 118,353, Sept. 25, 1917. In a process of refining oils, applicable, *e. g.*, for reclaiming waste lubricating oils, the oil is treated with kieselguhr or like diatomaceous earth and subsequently filtered. The oil so purified may be distd. to remove volatile impurities and thereafter again treated with the kieselguhr, etc., and filtered. A suitable plant is specified.

**Extracting oil, wax resins, etc.** J. MACGREGOR. Brit. 118,461, Aug. 30, 1917. In extg. oil, wax, resins, etc., from bone charcoal, fuller's earth, etc., the substance to be treated is made into a paste or emulsion with  $H_2O$  previous to treatment with a solvent, which, with the substance to be extd. in soln., is removed by decantation, the solvents used being lighter than  $H_2O$ . The provisional specification states that the  $H_2O$  may be mixed with the solvent instead of the substance to be treated.

**Catalysts for hydrogenating oils.** K. KIMURA. Brit. 118,323, Aug. 22, 1917. A catalyst for use in hydrogenating oils is prepd. by passing  $NH_3$  or a volatilized  $NH_4$  salt over a heated mixt. of a powdered Ni salt and a non-catalytic incombustible substance such as powdered asbestos, infusorial earth, or pumice. A Ni salt such as the nitrate, sulfate, chloride, formate, acetate, or oxalate is heated to about  $400^\circ$  after intimate mixt. with powdered inert material, in a vessel of non-catalytic substance and  $NH_3$  or preferably  $NH_4Cl$  gas is led in while the material is stirred by an agitator. The prepd. Ni is agitated with the oil in an atm. of H in a machine such as is described in 113,232 (C. A. 12, 1423).

**Detergent.** A. W. FOREE. U. S. 1,280,698, Oct. 8. A material for cleaning textile fabrics is formed of rounded sand 5.75 lbs., fullers' earth 12 oz., NaCl 3 oz., soap 2 lbs., borax 3 oz. and  $NaNO_3$  1 oz. and absorbed ammonia, molded into the form of a solid block.

**Liquid detergent.** R. HUBBARD. U. S. 1,281,010, Oct. 8. A liquid mixt. suitable for cleansing painted and varnished surfaces is formed of soap 3,  $H_2O$  83.5, powdered pumice 5.5 and neutral petroleum oil 8 parts. The oil serves to hold the pumice in suspension in the liquid.

## 28. SUGAR, STARCH AND GUMS.

A. HUGH BRYAN.

**Valuation of raw sugars.** W. D. HORNE. *J. Ind. Eng. Chem.* 10, 809-12 (1918).

-The existing custom of purchasing raw sugars on their polarization alone is far from satisfactory because it does not take sufficient account of the endless variations in these sugars. Three additional tests are described. *To det. the yield and purity of the sugar after washing:* A satd. soln. of the raw sugar itself is made. 92 cc. of this soln. is made into a magma with 200 g. of the raw sugar. This is spun for 2 minutes in a 5-inch centrifugal and the weight and purity of the sugar are detd. after drying 2 hrs. at  $98^\circ$ . *To det. the amount of defecation required and the rapidity of filtration:* A definite amt. of a standard strength raw sugar soln. is treated with successive and increasing amts. of an acid Ca phosphate soln. of known strength and neutralized each time with standard calcium sucrate. After each treatment the test tube in which the expt. is carried out is heated and allowed to settle, and the minimum amt. of the acid phosphate which will cause rapid settling and give a clear supernatant liquor is noted. When this amt. has been detd., 100 cc. of a  $45^\circ$  Brix sugar soln. is defecated with the amts. of acid phosphate and calcium sucrate found necessary by the above

test, the soln. is heated to 190° F. and then filtered through a triple thickness of folded filter bag cloth. The time of filtration is noted. *To det. the readiness with which the sugar yields its color to bone black:* Ten g. of raw sugar are dissolved in 30 cc. of water, and boiled with 0.25 g. of Filtercel and 2 g. of bone black, finer than 60 mesh. The amt. of color absorbed may be estd. by comparing the color of filtrate against a tintometer standard. On the basis of the above tests, certain amts. should be added to or subtracted from the price paid for raw sugars by the refiners. J. K. DALE.

**The role of oxidases and of iron in the color changes of sugar-cane juice.** F. W. ZERBAN. *J. Ind. Eng. Chem.* 10, 814-7(1918).—Chlorophyll, saccharetin and anthocyanin do not account for all the color in sugar-cane juices. Several oxidizing enzymes have been reported as occurring in cane juices and Schneller has shown that part of the color is due to the interaction of ferric salts with polyphenols occurring in the juice. Further expts. were made to see if the dark color of cane juice could be explained on the basis of the iron-polyphenol reaction and the oxidation of the iron salts to the "ic" condition by the natural oxidases of the juice. Young cane shoots were used because, though they are rich in polyphenols, they contain very little coloring matter. When ground in a porcelain mortar the color was dark brown instead of the usual dark green of mill juice; however, when a trace of  $\text{FeSO}_4$  was added the usual dark green color was obtained. It is concluded that the first brown color was due to the action of oxidases upon the polyphenols, while the green was due to the combined action of the iron salt and the oxidases on the polyphenols. Cane shoots were cut up and dropped into water. The mixt. turned brown on standing. When the above expt. was repeated with boiling water the mixt. remained colorless for days. If either ferrous or ferric iron salts were added to a cold-water ext. of the shoots the dark green color was obtained. Ferrous iron added to a hot-water ext. of cane shoots gave a colorless soln. which slowly turned green. Ferric iron added to a hot-water ext. gave a dark green color immediately. These expts. show that the color of a raw juice depends upon the presence or absence of oxidizing enzymes and the presence or absence of iron salts. Tests were made to identify the oxidizing enzymes in the young shoots. The best method found was first to ext. slices of the shoots with alc. and then add these extd. slices to the test soln. A number of polyphenols were used in these expts., the tests being made in neutral, slightly acid and slightly alk. soln. The presence of both a laccase and also a tyrosinase was shown by the color reactions, especially with paracresol, hydroquinone, pyrogallol, guaiacol and tincture of guaiac. The test for oxidases with potassium iodide starch soln. also gave positive results. The activity of both laccase and tyrosinase diminishes rapidly, but the peroxidase reaction with  $\text{H}_2\text{O}_2$  and tincture of guaiac could be obtained in juices that had been preserved with toluene for weeks. J. K. DALE.

**The preparation of an active decolorizing carbon from kelp.** F. W. ZERBAN AND E. C. FREELAND. *J. Ind. Eng. Chem.* 10, 812-4(1918).—The giant kelps of the Pacific Coast were used as the basis for the experimental prepn. of carbons capable of decolorizing sugar solns. Three factors were found to have an important effect upon the decolorizing power of the final product, first the point in the process at which the sol. salts are washed out; second, the method by which the material is carbonized; third, the temp. to which the char, after carbonization, is heated in a closed vessel. The decolorization tests were made by adding 5 g. of the carbon under examn. to 200 cc. of a 3% soln. of low grade molasses, bringing the soln. just to the boiling point and immediately filtering through a folded filter. The resulting filtrate was then compared with one obtained under the same conditions, but with 5 g. of Norit as the decoloring agent. The material used consisted of three different samples (A) kelp dried in a rotary kiln, (B) incinerated kelp prepd. in a revolving incinerator, (C) kelp that had

been subjected to destructive distn. (A) was carbonized by charring in an open saucepan until fumes ceased to come off, or by heating in an iron retort with a  $\frac{1}{4}$ -in. descending iron condensing tube. The first series of expts. showed the effect of leaching with water and acids. Chars made as above were heated to bright redness in closed iron cylinders and leached with acid or water either before or after this heating. In each case a better decolorizing carbon was obtained by leaching after heating, rather than before. An especially active carbon was made by heating the incinerated kelp and then boiling out with acid followed by water. Expts. to det. the best method for carbonizing the kelp gave more or less uncertain results, due to experimental difficulties, but seemed to show that the best results were obtained when the raw material was carbonized quickly at a comparatively high temp. in such a way that the fumes could escape quickly. Carbonization alone is not sufficient to make an active decolorizing carbon. No matter what process was used in charring the kelp, it was found that the higher the temp. to which this char was heated in a closed vessel, the better was its decolorizing power. A good carbon was made in one operation by heating to redness a sample of dried kelp in a closed iron cylinder, but with one of the caps only loosely screwed on, then boiling it out with water and acid. It is suggested that the high N content of the kelp may be responsible for the great decolorizing power of the carbons made from it.

J. K. DALE.

The preparation of several useful substances from corn cobs. F. B. LA FORGE AND C. S. HUDSON. *J. Ind. Eng. Chem.* 10, 925-7(1918); cf. *C. A.* 11, 1956.—An address describing methods of prepn., products obtained, and uses. "The yields of the various products constitute approx. the following % of the wt. of the dry corn cobs: adhesive gum, 30; cryst. xylose, 5; AcOH, 2.5 to 3; cryst. glucose, 37."

F. W. SMITHER.

Extracting sugar by diffusion. L. NAUDET. U. S., 1,281,057, Oct. 8. Sugar is extd. from beets by passing the juices through a series of diffusion cells, successively recharged, the denser portions of the extn. juice are reheated and passed through the newly filled cell to raise the temp. of the material in it before extn. and less dense portions are withdrawn from the system.

Glucose. C. HOPKINSON. Brit., 118,651, July 3, 1917. Glucose is produced from carbonized waste, that is to say, the friable hydrocellulose obtained by treating waste textile materials contg. both animal and vegetable fibers with a mineral acid. The carbonized waste is boiled with mineral acid and neutralized, and the ppt. so formed is removed. In an example, 1 part of the waste is mixed with 3 parts of 65-70%  $H_2SO_4$ , and the mixt. is allowed to stand for 3-4 hrs., and is afterwards dild. till the liquor contains 1-2% acid. The dild. liquor is boiled for 1 hr. The product is neutralized with  $CaCO_3$ , the ppt. is filtered off, and the residual liquid is evapd. to obtain the glucose.

## 29. LEATHER AND GLUE.

ALLEN ROGERS.

Notes on the Procter-Hirst test for sulfite cellulose. FINI ENNA. *J. Am. Leather Chem. Assoc.* 13, 438-40(1918).—The author has noted Yocum and Nelson's letter (*C. A.* 12, 2140) expressing doubt as to the reliability of the Procter-Hirst reaction and calls their attention to the Appellius-Schmidt reaction (*C. A.* 9, 251) which he believes does not fail positively or negatively. An abstract of Appellius and Schmidt's methods for the detection of wood-pulp in exts. and leather and also means of differentiating between Neradol D and wood-pulp follows.

R. W. FREY.

**Notes on the Procter-Hirst test for sulfite-cellulose.** J. H. YOCUM AND E. S. NELSON. *J. Am. Leather Chem. Assoc.* **13**, 395-6(1918).—A continuation of the work mentioned previously (*C. A.* **12**, 2140) on the Procter-Hirst test (*C. A.* **3**, 2395). A liquor was prepd. from spruce wood by extg. with NaOH and nearly neutralizing with HCl. The liquor alone gave only a slight ppt. after 24 hrs. standing by the Procter-Hirst test. Fifty cc. of the liquor plus 4 cc. NaHSO<sub>3</sub> gave immediately a slight ppt.; 50 cc. of liquor plus 4 cc. NaHSO<sub>3</sub> when heated gave at once a heavy ppt.; the NaHSO<sub>3</sub> liquor alone gave a slight ppt. on standing. These expts. were repeated on the wood liquor after standing several days and gave the same results. After this 50 cc. of the wood liquor was evapd. with 4 cc. NaHSO<sub>3</sub> until the NaCl and other salts were largely pptd. The soln. was filtered and the filtrate gave a slight ppt. by the P.-H. test. The pptd. salts after washing in satd. soln. of NaCl were dissolved in H<sub>2</sub>O and gave no ppt. with the P.-H. test. However, on combining the soln. of the pptd. salts and the filtrate from them a heavy ppt. was given by the P.-H. test. This pptn. may have been aided by the presence of the NaCl. All these reactions seem to confirm the authors' original statement "that the lignones of themselves do not react with the P.-H. test but that the presence of the sulfo-radical in an org. complex apparently does precipitate. It is felt that the detn. of the presence of sulfite-cellulose liquors in tanning solns. needs further study and that too much credence cannot be given to this test."

R. W. FREY.

**The effect of hard water on tannins. Committee report.** T. A. FAUST. *J. Am. Leather Chem. Assoc.* **13**, 409-17(1918); cf. *C. A.* **11**, 2624.—The work was confined to the analysis of tanning exts. and liquors from them, using distd. H<sub>2</sub>O and hard waters artificially prepd. by the addition of chemicals in the proportion of 50 parts to 100,000. The following chemicals were used: CaH<sub>2</sub>(CO<sub>3</sub>)<sub>2</sub>, MgH<sub>2</sub>(CO<sub>3</sub>)<sub>2</sub>, CaSO<sub>4</sub>, MgSO<sub>4</sub>, and NaCl. The exts. employed were chestnut, chestnut oak bark, hemlock and quebracho. As a general thing when the exts. were dissolved in the artificial hard waters and analyzed by the usual method an appreciable loss of tannin was found, but when 50° Bk. liquors were made up from the exts. with these hard waters and then analyzed using distd. H<sub>2</sub>O practically no loss in tannin occurred. The results are tabulated and a brief discussion of the work is given.

R. W. FREY.

**Principles of extraction of tanning materials.** E. G. KEINER. *Hide and Leather*, Aug. 17, 29, 1918; *J. Am. Leather Chem. Assoc.* **13**, 512-4(1918).—A brief discussion of the open and closed methods of extg. tanning materials. The advantages of the latter are: easier and better movement of the liquor and a cleaner liquor with less color. There is also a saving of 30 to 40% in steam with the closed method. The cost of repairs is less in the closed extraction.

R. W. FREY.

**Leather substitute.** G. H. BRUCE. U. S., 1,280,957, Oct. 8: A material for the manuf. of shoe soles is formed of a sheet of rubber mixed with fiber (e. g., cotton) glued to a sheet of cardboard or other material which can be molded under heat and pressure to form shoe arches. Cf. *C. A.* **12**, 2712.

**Glue, etc.** L. MAUERHOFER. *Brit.*, 118,119, Aug. 9, 1918. In digesters for the steam treatment of glue and the like, more especially in the leather industry, the glue instead of being treated in the mass, is placed in thin layers on perforated plates fitted one above the other on a central perforated pipe, which distributes the steam rising from the lower part of the digester. The glue accumulates in a reservoir removable bodily with the perforated plates. In a modification, the reservoir is replaced by a perforated plate through which the glue passes directly into the H<sub>2</sub>O below.

# CHEMICAL ABSTRACTS

Vol. 13.

JANUARY 20, 1919.

No. 2

## I. APPARATUS.

L. C. JONES.

Extraction apparatus for the laboratory. BESSON. *Mitt. Lebensm. Hyg.* 9, 234 (1918).—Although never experiencing the objections of Schwalbe and Schulz (*C. A.* 12, 2145) regarding his extn. app. (*C. A.* 10, 133), B. believes their improvements to be valuable.

H. A. LEPPER.

A special stopcock for dropping liquids arranged for equalizing the pressure above and below the outlet in the stopcock. HARRY L. FISHER. *J. Ind. Eng. Chem.* 10, 1014-5 (1918), illus.

E. J. C.

A new timing device for simplifying the thermometric reading of calorimetric determinations. CHAS. A. MYERS, JR. *J. Ind. Eng. Chem.* 10, 1015-6 (1918), illus.

E. J. C.

Notes on the use of the pressure gage for Pitot-tube measurement. EVALD ANDERSON. Lab. Western Pptn. Co., Los Angeles. *Chem. Met. Eng.* 19, 250 (1918).—The difficulty usually experienced with such pressure gages due to the shift of the zero point is overcome by fitting each connection tube with a T and nipple just above the gage and connecting the two by a rubber tube on which there is a Hoffman clamp. By opening the clamp and thus equalizing the pressure the zero point can be read without the trouble of removing the Pitot-tube from the flue or disconnecting one side of the gage.

F. A. HARVEY.

A new method of microscope illumination. A. SILVERMAN. Univ. Pittsburgh. *Chem. Met. Eng.* 19, 508-9 (1918).—The following improvements have been made on the app. described previously (*C. A.* 12, 1606). A new 9-volt, 0.7 amp. daylight lamp has been devised which will give 50% greater illumination. A tube resistance permits use on 107, 112, and 118 v. a. c. or d. c. A shutter has been devised for cutting off the light from half the field. Excellent photomicrographs are obtainable with the new lamp.

F. A. HARVEY.

A new illuminator for microscopes. II. ALEXANDER SILVERMAN. *J. Ind. Eng. Chem.* 10, 1013-4 (1918); illus.; cf. *C. A.* 11, 2977; 12, 1606; and preceding abstr.

E. J. C.

The Abbé and Pulfrich refractometers. ANON. *Engineering* 106, 282-3 (1918).—New types of these instruments are described. The Abbé instrument is designed for rapid detn. of a liquid or solid to the 3rd or 4th decimal place within the range 1.3 to 1.7. By means of an attachment to the telescope daylight or artificial light can be used and by means of a circular scale on this attachment the dispersion between the C and F hydrogen lines can be detd. The liquid film is contained between the 2 hypotenuse faces of 2 dense flint glass prisms. The upper prism has the face polished and the critical edge for total reflection acts as the dividing line which is set on the cross hairs. The corresponding face of the lower prism is grayed to prevent false images. The prisms are water-jacketed and the temp. thermostatically controlled. The instrument may be used for solids. When used in the sugar industry it is supplied with an additional scale giving directly the % of "dry substance" at the standard temp. of 20 or 28°. One of the modifications of the latest design of the Pulfrich

refractometer concerns the micrometer attachment. The arm which clamps the circle and the clamping device are so made that the micrometer readings are accurate without using a correction curve. Each prism is water-jacketed. Another water jacket can be placed over the top of the prism so that only the necessary vertical face is left free. This jacket automatically assumes its correct position as a screw is tightened.

Accurate method for measuring the density of gases. O. MAASS AND J. RUSSELL. McGill Univ. *J. Am. Chem. Soc.* 40, 1847-52 (1918).—The vol. of the gas is detd. in a large bulb packed in ice, and the gas is then condensed by means of liquid air into a small tube for weighing. An accuracy of 0.05% is attainable. The values at zero and 1 atm. were: acetylene 1.1695,  $\text{Me}_2\text{O}$  2.1103, and  $\text{HBr}$  3.6397. F. C. HOYT.

Latent heat of fusion as the energy of molecular rotations. KÔTARÔ HONDA. *Sci. Rep. Tohoku Imp. Univ.* 7, 123-30 (1918).—In the mols. of a solid there are rectilinear vibrations about a mean position, and small dependent rotational vibrations about central nuclei. At fusion, the rotational vibrations become complete revolutions. The latent heat of fusion is shown to consist of the energy of rotation gained during fusion:  $w\lambda = nE_{T_m}/2$ , where  $E_{T_m}$  is the energy of 1 g. mol. of liquid,  $n$  the degrees of freedom,  $w$  the at. wt., and  $\lambda$  the latent heat of fusion. By expt. H. proved that for the elements (except where the sp. heat is abnormal or a transformation takes place during fusion),  $w\lambda/T_m = nE_{T_m}/2T_m$ , i. e., that the latent heat of fusion consists of the energy of rotation gained by the mols. during fusion. By arbitrarily choosing  $n$ , the same relation is shown to hold for diatomic compds.; but owing to the ambiguity in the value of  $n$ , this is not taken as proof of the theory. Further evidence is cited in the fact that amorphous substances have little or no latent heat of fusion; they are very viscous liquids and already have the rotational energy characteristic of liquids. Also in *Phys. Rev.* 12, 425-30 (1918). IRENE F. SMITH.

Mutual action of calcium and magnesium salts on their diffusion through colloids, and the physiological meaning of these salts. T. TADOKORO. *J. Tokyo Chem. Soc.* 39, 423-39 (1918).—The diffusion of  $\text{CaCl}_2$ ,  $\text{CaI}_2$ ,  $\text{Ca}(\text{NO}_3)_2$ ,  $\text{CaHPO}_4$ ,  $\text{MgCl}_2$ ,  $\text{MgI}_2$  and  $\text{MgSO}_4$  through colloids, such as milk and the press juice of the young leaves of *Tsai*, was studied. The diffusion velocity of Ca is increased in the presence of Mg salts and that of Mg is retarded by Ca salt. Glucose solns. also diffuse quickly through vegetable cells in the presence of Ca salts but not of Mg salts. S. KOMATSU.

**Chemical resistance. II. Application of the quantum theory in chemical dynamics.** S. HORIBA. *J. Tôkyo Chem. Soc.* 39, 369-86(1918); cf. *C. A.* 10, 2168.—This is an extension of the view of Lewis (*C. A.* 9, 263; 11, 112, 2293). H. assumes that a substance reacts when the mol. absorbs a certain amt. of energy from the surrounding medium and is changed into its active form. The chem. resistance of the reaction system has been expressed as a sum of 2 terms (1) a term proportional to the probability of transmission of energy which must be given to a mol. in order to make the mol. reactive, (2) a term inversely proportional to the probability of migration of the active mass into the sphere of reaction. On the same principle, he proposes a new process of calcn. of the affinity const. S. KOMATSU.

**The variation of electric resistance during the fusion of metals.** HIDRO TSUTSUMI. *Sci. Rep. Tôhoku Imp. Univ.* 7, 93-105(1918); cf. *C. A.* 12, 2274.—In this investigation the sp. resistances of Hg, Sn, Bi, Pb, Zn, Sb, Al, Ag and Cu were studied during fusion. The ratio of sp. resistance of a metal in the liquid and solid state is approx. 2, except for Bi and Sb, whose ratio is roughly  $1/2$ . Probably due to chance,  $WL/T_m$  is also nearly equal to 2, where  $W$  is the at. wt. of the metal,  $L$  the latent heat of fusion, and  $T_m$  the abs. m. p. The abrupt increase in sp. resistance at the moment of fusion is accounted for by the author on the basis of the electron theory as follows: The no. of impacts of free electrons (whose mean velocity is small compared with that of the revolving bound electrons) with revolving electrons increases proportionally with the amplitude of rotational vibration. This latter, at the point of fusion, changes to complete revolution, causing discontinuous change in the number of impacts and hence in the sp. resistance. IRENE F. SMITH.

**The abnormality of strong electrolytes. III. The osmotic pressure of salt solutions and equilibrium between electrolytes.** JNANENDRA CHANDRA GHOSH. *J. Chem. Soc.* 113, 707-15(1918); cf. *C. A.* 12, 1609, 2268.—Clausius has devised an equation of state free from any arbitrary assumption:  $PV = 2/3$  kinetic energy —  $1/3$  virial. From Part I,  $A = nRT \log \mu_\infty/\mu_p$  and  $A$  is the virial. Hence,  $PV = nRT - 1/3 nRT \log (\mu_\infty/\mu_p)$  or  $nRT (1 - 1/3 \log (1/a))$ , where  $a$  is the activity coeff. From the Clausius equation, the value of van't Hoff's  $i$  is  $n (1 - 1/3 \log (1/a))$ . The values of  $a$  for bivalent strong electrolytes corrected for the viscosity ratio  $\eta/\eta_\infty$ , are here applied. From these values of  $a$ ,  $i$  is computed and compared with the corresponding values from the freezing-point lowering data of Noyes and Falk. The agreement between the observed values and those computed from the Clausius equation varies from 0.05% to 0.4%, while with the Arrhenius equation it is from 1% to 2.5%. For ternary electrolytes the Clausius equation gives by far the better values. For mixed solns.  $\log (1/x') = \log (1/y') = k (2/(V + V'))^{1/2}$  is obtained, where  $x'$  and  $y'$  are the activity coefficients of the components,  $V$  and  $V'$  their respective dilns., and  $k$  is a const. F. C. HOYT.

**Electrolytic conductivity in non-aqueous solutions. II. The electrical conductance of trimethyl-*p*-tolylammonium iodide in water and several organic solvents.** HENRY JERMAIN MAUDE CREIGHTON and D. HERBERT WAY. Swarthmore College. *J. Franklin Inst.* 186, 675-98(1918).—The cond. of this compd. was detd. in aq. soln., and in soln. in each of the following solvents: MeOH, EtOH, propionaldehyde, benzaldehyde, anisaldehyde, acetone, HCOOH, AcOH, EtCN, PhCN, nitromethane, nitrobenzene, and epichlorohydrin. The temp. of the expt. was usually 25°. In aq. soln. Ostwald's diln. law was not followed; however,  $k$  did not vary with the concn. of the solute when the equation of Storch was used, i. e.,  $\alpha^n + (1 - \alpha) v^{n+1} = k$ . The conductance in aq. soln. at 25° was found to be 40.3. The equiv. cond. at infinite diln., detd. by calcn. or extrapolation, varied from 13 for anisaldehyde to 188 for acetone, the temp. being 25°; it was greater in an aliphatic solvent than in the corresponding

aromatic solvent; in an homologous series, it was greater the nearer the solvent stood to the beginning of the series; its magnitude was influenced most by the aldehyde group, least by the carboxyl group; among the values obtained were: nitromethane 115, nitrobenzene 38, EtCN 143, PhCN 54, propionaldehyde 120, benzaldehyde 33, water 116, Me alc. 100, Et alc. 48, HCOOH 90, AcOH 25, epichlorohydrin 44. By the same procedure, the equiv. cond. at infinite diln. was found to be 28 for Et alc. at 0°, 29 for benzaldehyde at 18°, 36 for nitrobenzene at 18°, and 145 for acetone at 18°.

JOSEPH S. HEPBURN.

Artificial coloration of spherulites with helicoidal development (tartrates and bimalates). PAUL GAUBERT. *Compt. rend.* 167, 368-70(1918); cf. Wallerant, *C. A.* 1, 1958.—The spherulites are easily obtained by the evapn. of a very thin layer of soln. upon a plate of glass. The temp. and velocity of crystn. have an important influence upon the production of the spherulites. Ammonium bimalate gave only hemihedral forms ( $1/2$ , b.  $1/2$ ) when the soln. was heated to incipient decompn. These forms rarely appear and have not been obtained by other observers. The helicoidal structures show the existence of enantiomorphous forms. Optical examn. shows that the development is not the same in all of the spherulites. By coloring the crystals during growth with methylene blue the internal condition of the crystals indicated by pleochroism is shown. A soln. of  $\text{NaHC}_4\text{H}_4\text{O}_6$  evapd. at different temps. gives crystals or spherulites of varying optical properties. By coloring with methylene blue the spherulites of the hydrated salt appear violet-blue and those of the anhydrous salt red-violet, all very pleochroic. Bitartrates of  $\text{NH}_4$ , Rb, and Tl yield helicoidally developed spherulites of which the fibers and simple crystals are colored by methylene blue. The max. absorption is independent of the sign of the crystal, the mechanism of the coloration being the same as that of the crystals or fibers of ammonium bimalate or  $\text{NaHC}_4\text{H}_4\text{O}_6$ .

L. W. RIGGS.

The determination of the limiting values of the medium refractive index of a finely crushed biaxial crystal by the immersion method. SEITARO TSUBOI. *J. Geol. Soc. Tokyo* 35, 38-41(1918).—The following method for the detn. of  $\beta$  is presented, based on the principle (of which proof is given) that the value of  $\beta$  is always between the two  $n$ s to be observed in a crystal grain of any orientation. The finely crushed fragments of a biaxial crystal are immersed successively in liquids of different  $n$  and the detn. is made on each fragment whether the  $n$  of the liquid  $p$  is above or below or lies between, the two values of  $n$  of the fragment,  $n_1$  and  $n_2$ . If the results are  $n'_1 < n'_2 < p'$  in any one trial and  $p'' < n''_1 < n''_2$  in another, then  $\beta$  will be detd. from the relation:  $n_1 \leq \beta \leq n_2$  as  $p'' < \beta < p'$ . The difference between the upper and lower limiting values of  $\beta$ ,  $p' - p''$ , may be made as small as 0.003 by repeating the process on a large no. of grains of various orientation, with different liquids.

S. G. GORDON.

Crystallography and optical properties of three aldopentoses. EDGAR T. WHERRY. *Bur. Chem. J. Am. Chem. Soc.* 40, 1852-8(1918).—The isomers available for crystallographic study were  $\alpha$ -d-lyxose,  $\alpha$ -d-xylose, and  $\beta$ -d-arabinose. A complete description of their crystals is given, and striking relationships in angles are pointed out. The same 3 and also  $\alpha$ -l-arabinose were examd. optically; the results are given in detail. The sp. grs. were also detd. by suspension, and the refractivities calcd., the values being somewhat less than the theoretical. Finally a determinative table is presented for the rapid and certain identification of these sugars by their optical properties as observed under the microscope.

### 3. SUBATOMIC PHENOMENA AND RADIOCHEMISTRY.

GERALD L. WENDT.

The interference fringes developed by friction and electricity in certain anisotropic liquids. F. GRANDJEAN. *Compt. rend.* 167, 494-6(1918).—Exptl. observations are made upon a number of substances capable of forming liquid crystals, using a microscope both with and without nicols, and plates of different solids. Friction or electricity develops a particular structure which is such that light waves in traversing undergo interference and display color. The same phenomenon is observed with reflected light for friction only and may be explained by the fact that such light is more intense in the regions which show color in transmitted light than in the normal regions. The colors persist only momentarily after friction has ceased, or with the disappearance of the elec. field.

G. L. CLARK.

Absorption spectra of aqueous solutions of complex nickel, chromium and copper salts. Y. SHIBATA AND K. MATSUNO. *J. Tokyo Chem. Soc.* 39, 661-706(1918).—The absorption spectra of aq. solns. of the following salts were studied:  $[\text{Cr}(\text{NH}_3)_6]\text{Cl}_3$ ,  $[\text{Cr en}_3]\text{Cl}_3$ ,  $[\text{Cr en}_3](\text{SCN})_3$ ,  $[\text{Cr}(\text{NH}_3)_5\text{Cl}]\text{Cl}_2$ ,  $[\text{Cr}(\text{NH}_3)_5\text{H}_2\text{O}]\text{Cl}_2$ ,  $[\text{Cr}(\text{NH}_3)_5(\text{SCN})](\text{SCN})_2$ ,  $[\text{Cr}(\text{NH}_3)_5\text{Cl}\cdot\text{H}_2\text{O}]\text{Cl}_2$ ,  $[\text{Cr}(\text{NH}_3)_4\text{Cl}_2\cdot\text{H}_2\text{O}]\text{SO}_4$ ,  $[\text{Cr en}_2\text{Cl}_2]\text{Cl}$ ,  $[\text{Cr}(\text{NH}_3)_3\text{Cl}_3\cdot\text{H}_2\text{O}]\text{NO}_3$ ,  $\text{Cr}(\text{NH}_3)_3(\text{SCN})_3$ ,  $[\text{Cr}(\text{NH}_3)_2\text{Br}_2(\text{H}_2\text{O})_2]\text{Br}$ ,  $[\text{Cr}(\text{NH}_3)_2(\text{SCN})_4]\text{NH}_4$ ,  $\text{Cr}(\text{SO}_4)_3\cdot 18\text{H}_2\text{O}$ ,  $\text{Cr}_2(\text{SO}_4)_3\cdot 6\text{H}_2\text{O}$ ,  $[\text{Cr}(\text{C}_2\text{O}_4)_3]\text{K}_3$ ,  $[\text{Cr}(\text{SCN})_6]\text{K}_3$ ,  $\text{CrO}_3\cdot 3\text{NH}_3$ ,  $\text{CrO}_4\cdot 3\text{KCN}$ ,  $[\text{Ni}(\text{NH}_3)_6]\text{Cl}_2$ ,  $[\text{Ni}(\text{NH}_3)_6]\text{SO}_4$ ,  $[\text{Ni}(\text{N}_2\text{H}_5)_3]\text{Cl}_2$ ,  $[\text{Ni en}_3]\text{Cl}_2\cdot 2\text{H}_2\text{O}$ ,  $2\text{NiSO}_4\cdot 5\text{NH}_3\cdot 7\text{H}_2\text{O}$ ,  $(\text{NH}_4)_2\text{Ni}(\text{SO}_4)_2\cdot 6\text{NH}_3\cdot 3\text{H}_2\text{O}$ ,  $[\text{Ni}(\text{NH}_3)_4]\text{SO}_4\cdot 2\text{H}_2\text{O}$ ,  $[\text{Ni}(\text{N}_2\text{H}_5)_2]\text{Cl}_2$ ,  $[\text{Ni en}_2]\text{Cl}_2\cdot \text{H}_2\text{O}$ ,  $[\text{Ni}(\text{NH}_3)_3]\text{Cl}_2\cdot 3\text{H}_2\text{O}$ ,  $\text{NiSO}_4\cdot 7\text{H}_2\text{O}$ ,  $\text{NiCl}_2\cdot 6\text{H}_2\text{O}$ ;  $[\text{Cu}(\text{Py})_4](\text{NO}_3)_2$ ,  $[\text{Cu}(\text{Py})_4](\text{NO}_3)_2$ ,  $[\text{Cu}(\text{Py})_3](\text{NO}_3)_2$ ,  $[\text{Cu}(\text{Py})_2](\text{NO}_3)_2$ ,  $\text{Cu}(\text{NH}_3)_2(\text{C}_2\text{H}_5\text{O}_2)_2$ ,  $\text{Cu}(\text{NH}_3)_2(\text{C}_2\text{H}_5\text{O}_2)$ ,  $\text{Cu}(\text{NH}_3)_2\text{Cl}(\text{C}_2\text{H}_5\text{O}_2)\cdot \text{H}_2\text{O}$ ,  $\text{Cu}(\text{C}_2\text{H}_5\text{O}_2)_2\cdot \text{H}_2\text{O}$ ,  $\text{Cu}(\text{NH}_3)_2\text{C}_2\text{O}_4$ ,  $\text{Cu}(\text{NH}_3)_4\text{C}_2\text{O}_4\cdot 2\text{H}_2\text{O}$ ,  $\text{Cu}(\text{NH}_3)_2\text{C}_2\text{O}_4$ ,  $\text{CuNH}_3\cdot \text{C}_2\text{O}_4$ ,  $\text{Cu}(\text{NH}_3)_4\text{SO}_4$ ,  $\text{Cu}(\text{NH}_3)_6\text{SO}_4$ ,  $\text{CuSO}_4\cdot 5\text{H}_2\text{O}$ ,  $\text{CuCl}_2\cdot 2\text{H}_2\text{O}$ . *Conclusions:* (1) Cr complexes stable in aq. soln. show 2 or 3 absorption bands which vary according to the nature of the groups with which Cr is associated. All rules for Co complexes apply to Cr compds. (2) Ni salts unstable in aq. soln. show 2 max. absorptions in the neighborhood of  $\lambda$  1700 and 2800. (3) Cu complexes being very unstable in the aq. soln. have the tendency to decompose into their components. They show only end absorption in red or violet region which is characteristic of the Cu complex.

S. KOMATSU.

The structure of the bismuth line  $\lambda$  4722. LESTER ARONBERG. Univ. Chicago. *Astrophys J.* 47, 102-3(1918).—The results of Lunelund (*Ann. Physik* 34, 305(1911)), and Wali-Mohammad (*C. A.* 8, 3393), are incorrect. The true wave length of each of the components, in international units, starting with the strongest one is as follows: 4722.379, -.435, -.481, -.619, -.663, -.697.

F. A. HARVEY.

Spectrum of the isotopes of lead. LESTER ARONBERG. Univ. Chicago. *Astro-phys. J.* 47, 96-101 (1918).—The line  $\lambda$  4058 has a wave length 0.0045 Å longer for radio-lead from Australian carnotite, at. wt. 206.318, than for ordinary Pb. This agrees in sign but is about 100 times greater in magnitude than the shift calcd. from Bohr's equation. The fact that there is an actual shift of the line in the ordinary Pb and not a mere broadening suggests that ordinary Pb is a pure isotope and not a mixt. of radium and thorium Pb.

F. A. HARVEY.

#### 4. ELECTROCHEMISTRY.

COLIN G. FINK.

**Electric furnace in the steel foundry.** W. E. MOORE. *Iron Age* 102, 1206-7 (1918).—The increasing use of elec. furnaces in the steel foundry is noted and the use of an acid-lined type, so designed and constructed that it is adaptable to basic operation, is advised. A comparison is given of costs of converter and acid elec. steel. All possible facilities should be utilized and the best type of equipment under existing power supply used. Tractor and truck fields provide a growing market for high-grade steel castings, as well as railroads, agricultural implement manufacturers, and machine tool builders.

W. A. BOYNTON.

**Electric furnaces in metallurgy. The Heroult furnace.** ANON. *Electrician* 81, 538, 608 (1918).—A comprehensive illus. description. The cost at the present time is difficult to estimate exactly, and varies considerably at different works. The great advantage possessed by the elec. furnace at the present time is that it can melt miscellaneous steel scrap alone without the addition of any pig Fe, and make a large variety of steel of remarkable purity. The main costs are as follows: (a) *Power*: This varies from 650 to 800 K.W. hrs. per ton, according to the nature of the scrap, the material to be made and the efficiency of the shop. (b) *Labor*: One melter, one helper and one or two laborers are employed on the furnace itself. (c) *Electrodes*: The consumption of amorphous C electrodes is usually from 30-40 lb. per ton, and of graphite electrodes 12-16 lbs. per ton of steel cast. (d) *Repairs*: This is not an expensive item. The life of the roof varies with the size of the furnace and other conditions between 80 and 200 heats; the bands are fettled with dolomite between the heats. (e) *Other Charges*: Additions, tools, overhead charges, ladle, etc., vary greatly according to the class of steel made and the shop conditions. Owing to the high quality of a large proportion of the turnings now available it is frequently unnecessary to refine, and in this case an acid lining presents many advantages. The expensive magnesite brick is avoided, the roof lasts longer as it is not splashed with lime, and in the case of foundries, scrap castings, etc., covered with sand, can be re-melted without cutting the lining, as in the case of a basic furnace. The furnace can be converted into a basic furnace at any time by changing the lining, no other alterations being necessary.

**New type of electric furnace.** ANON. *Elec. Rev. West. Elec.* 73, 950 (1918).—Brief description of the Greene Furnace. It is of the rolling cylinder, arc type. The 3-ton furnace at Seattle has 2 5-inch graphite electrodes requiring from 500 to 600 kw. 2-phase, 100 to 110 volts. A 3-ton charge of scrap steel is melted in 2 to 3 hrs. The scrap is deoxidized by the Greene slag process, the slag being composed of sand, clay or lime. The slag dissolves the Fe oxides which are in turn reduced by adding powdered coke or ferro-Si to the charge. The elimination of Fe oxides obviates imperfect castings due to blow holes. The newer type of 3-ton furnace has 3 electrodes, 3 phase current and a 400 kva. transformer. The shell of the furnace is made of 3/4-inch boiler plate.

Some recent advancements in the electrical industry of the United States. E. W. RICE. *Rev. gén. sci.* 29, 551-4(1918). E. J. C.

Electric smelting of ferromanganese ores in California. ANON. *Elec. Rev. West. Elec.* 73, 940(1918).—The two 3-phase Noble furnaces at Heroult are smelting 400 tons of ferro-Mn ore per month. The ore averages 45% Mn and 15% SiO<sub>2</sub>. The product contains 70% Mn. The elec. supply is 2600 to 3000 kw., a. c., 60 cycle, 40 to 80 volts on the secondaries. C. G. F.

Electric treatment of airplane forgings. D. D. MILLER. *Iron Age* 102, 381-5 (1918).—A detailed description of a recent installation of a Baily furnace for heat-treating axle forgings at the plant of the Ingalls-Shepard Forging Co. The forgings pass through a stationary resistance reverberatory elec. furnace, are discharged into a quenching tank, and deposited in the drawing furnace, in one continuous process. The furnace is an automatic pusher type and consists of two parts, the first for hardening and quenching, and the other for the drawing process. Each part comprizes a stationary rectangular metal enclosure containing a hearth 20 ft. X 7 ft. insulated by means of high-grade fireclay bricks. The furnace will heat 72 tons in 24 hrs. to 870°. The first part is rated at 600 kw. and designed for 2-phase 60-cycle operation, the second at 300 kw. and operates on single-phase. The heating troughs are rectangular, open at the top, and consist of a highly refractory carbide mixed with a binder. The troughs are filled with finely broken C or graphite, which acts as a resistor. The current is supplied by Cu electrodes fastened to the ends. At either end of both sections of the furnace are heat-insulated charging- and discharging-doors which are counterweighted and slide up and down. A hydraulic manipulator located between the discharge end of the heating section and the charging end of the drawing section removes the material from the heating section, quenches it and places it on the operating platform of the drawing section from where it is charged into this section by the pusher mechanism. The entire automatic operation is accomplished by hydraulic power, with the exception of the motor-driven time limit device used in the quenching operation. Material requires 3 hrs. for passage through both sections. Results indicate attainment of the desired precision and uniformity of treatment.

W. H. BOYNTON.

Ceric oxychloride produced by the electrolysis of cerous chloride. H. ARNOLD. *Z. Elektrochem.* 24, 137-8(1918); *J. Soc. Chem. Ind.* 37, 505-6A(1918).—A brown amorphous hygroscopic deposit is produced on the cooler parts of the anode upon electrolysis of fused CeCl<sub>3</sub>. It consists of NH<sub>4</sub>Cl, CeOCl<sub>2</sub> and water. CeOCl<sub>2</sub> is produced only while the melted CeCl<sub>3</sub> contains water.

W. H. BOYNTON.

Manufacture of mine disinfectant. ANON. *Eng. Mining J.* 106, 786(1918).—Hypochlorite is used at the Falcon mine in Rhodesia for treating wounds, washing out drinking buckets, etc. Electrolysis is effected in a wooden box, the electrodes consisting of six C anodes and six C cathodes. The anodes must be of high grade. A continuous current passes through salt soln.; the resultant hypochlorite is clarified in a sand filter and transferred to earthenware jars.

W. H. BOYNTON.

Electroplating engineering. C. B. WILLMORE. *Metal Ind.* 16, 209-11, 364-5, 466-7(1918); cf. *C. A.* 10, 855 2072; 12, 1151.—These instalments deal with problems of elec. measurements, tracing current leakage, voltage losses and their prevention, conductivity of plating solns. and study of conductance as a factor in roto-plater design.

W. H. BOYNTON.

Transformer for laboratory tests. GUINO LAZZARINI. *Rome. Ann. chim. applicata* 10, 1-22(1918).—A transformer is described having the following advantages: (1) It permits variation of a. c. between the limits of 5-440 volts. (2) It will furnish

2500 amp. at 5-10 volts. (3) Changing of the ratios of transformation is easy and rapid, even by one unskilled in the use of the app. The transformer is applicable to calibrating of elec. instruments, and elec. furnace operation. A description of the app. is given, together with illus. and methods of using it. R. S. POSMONTIER.

**Electrically heated ovens.** ANON. *Elec. Eng.* 52, No. 6, 28(1918).—Refers in particular to enameling ovens; Kiln type oven, hand operated: 6 to 8 lbs. of work (sheet iron, etc.) per kw. hr.; kiln type oven, truck operated, 10 to 12 lbs.; continuous conveyor-type oven, 25 to 30 lbs. C. G. F.

The behavior of phosphates at the anode (FICHTER, MÜLLER) 6. Electrolytic oxidation of benzene (CLAUDIUS) 10. Electric furnace for laboratory use (U. S. pat. 1,283,285) 1.

HALE, A. G.: *The Application of Electrolysis in Chemical Industry.* London: Longmans, Green & Co. 148 pp. 7s. 6d.

**Arc-lamp electrode.** I. LADOFF. U. S. 1,281,796, Oct. 15. Electrodes capable of producing a relatively steady arc are formed of  $\text{Fe}_2\text{O}_3$  14, Fe 9, Ti oxide or ilmenite 17, Na uranate 0.46 and Cr oxide 1.25 parts.

**Carbon electrodes.** S. E. SIEURIN. U. S. 1,282,475, Oct. 22. Electrodes for electric furnaces are formed by heating the electrode material such as anthracite or coke in an elec. resistance furnace to near the temp. at which the C would be graphitized. This treatment serves to produce electrode material of good conductivity and resistance to burning.

**Carbon furnace electrodes.** S. E. SIEURIN. Brit. 119,164, Dec. 15, 1917. Anthracite, coke, or other carbonaceous material is converted into a product suitable for the manuf. of furnace electrodes by heating it in an elec. furnace to a temp. between 1800 and 2000° which is a little below that of graphitization. An energy consumption of 1000 kw. hr. per ton is sufficient, i. e., about a third of that generally necessary for transformation to graphite.

**Electrodes for deposition of copper from solutions.** W. K. PAGE. U. S. 1,283,280, Oct. 29. In making electrodes of silicon-Fe in metal molds, the mold is preheated to about 300°, the molten metal is cooled to about the lowest temp. at which it is still sufficiently fluid to be cast and is then poured into the mold. Cu lugs are cast into the electrode and it is removed from the mold while still at about a cherry-red heat and tempered in a bed of kieselguhr to give it a dense, fine resistant structure for a considerable distance from the surface.

**Securing connecting parts of battery plates.** I. M. NOBLE. Can. 187,244, Oct. 29, 1918. The connector post of battery plates is secured to the battery cover by inserting the post through an aperture in the cover, then heating the part of the post above the cover to fuse the metal slightly and pressing the metal down around the edge of the opening in the cover. The tool for use in this process is specified.

**Molded electric conductors.** J. P. A. MCCOY. Can. 187,645, Nov. 26, 1918. An elec. conductor composed of a molded mass of pulverulent conducting material bound together with a binder containing at least one of a group of substances such as indene, coumarone and their isomers and polymerization products is made by molding the material with the binder and heating to expel nearly all the binder.

**Electric battery.** H. WILHELM and H. OLANETA. U. S. 1,283,005, Oct. 29. Battery electrodes of C are wrapped with paper or other non-porous material, to prevent undesirable penetration of material placed around the paper casing.

**Dry-cell electric battery.** I. PLETCHER. U. S. 1,283,292, Oct. 29. A soln. for recharging dry cell batteries is formed of HOAc 2 oz., "acid vinegar" 1 qt., salicylic acid 1 oz. and phenol 0.5 oz. .

**Dry-cell electric battery.** E. H. ROLLINSON. U. S. 1,284,458, Nov. 12. Structural features.

**Dry cells.** C. HAMBURCHEN. Can. 187,416, Nov. 12, 1918. A cold soln. of  $\text{ZnCl}_2$  and  $\text{NH}_4\text{Cl}$  is prepd. and mixed with a cereal; then the cold mixt. is introduced into the container around the electrodes and allowed to gelatinize thereon. The electrolyte thus comes into direct contact with the Zn cup and the negative electrode and no space is occupied by inert bibulous material.

**Dry-cell electric battery.** E. L. MARSHALL. U. S. 1,281,409, Oct. 15. Zn cans of dry-cell batteries are lined with cloth or paper. Wet uncooked flour paste is applied to the dry lining and dried upon it before the lining is placed in the Zn can and after placement in the can the lining and flour paste are moistened to secure uniform action on the Zn.

**Dry-cell electric batteries.** L. R. RHOADES. U. S. 1,281,421, Oct. 15. The pat. relates to a method of fixing a bibulous lining in a Zn can by use of paste.

**Primary electric battery.** R. W. ERWIN. U. S. 1,282,057, Oct. 22. A negative element formed of a mixt. of Cu oxide and S is used in a primary elec. battery with an alk. electrolyte. Use of 1-5% of S effects an increase of about 0.2 volt in the voltage of the battery.

**Storage battery.** J. A. WOOD. U. S. 1,282,159, Oct. 22. Structural features.

**Storage battery.** W. MORRISON. U. S. 1,284,746, Nov. 12. Structural features.

**Storage battery.** W. MORRISON. U. S. 1,284,424, Nov. 12. Structural features.

**Negative plate for storage batteries.** W. MORRISON. U. S. 1,284,425, Nov. 12. In the manuf. of storage battery negative plates, the grid is sand-blasted, filled with Pb oxide and the latter is then electrolytically reduced to spongy Pb in a soln. of  $\text{MgSO}_4$ , which effects an intimate association of the reduced Pb with the metal of the grid.

**Storage battery electrode.** W. MORRISON. U. S. 1,284,426, Nov. 12. In forming storage battery electrodes, the filler mass, which may be formed from  $\text{PbO}$ ,  $\text{Pb}_2\text{O}_3$ ,  $\text{H}_2\text{SO}_4$ ,  $\text{H}_2\text{O}$  and  $\text{H}_2\text{O}_2$ , is satd. with  $\text{H}_2\text{O}$  and the plate is then formed in an electrolyte of  $\text{H}_2\text{SO}_4$ .

**Storage battery.** M. R. HUTCHISON and C. W. NORTON. U. S. 1,283,779, Nov. 5. Structural features.

**Depolarizer for electric batteries.** M. E. HOLMES. U. S. 1,281,372, Oct. 15. Ammonium phosphomolybdate is used as a depolarizing material in elec. batteries of the dry-cell type.

**Electric furnace.** J. O. BOVING. U. S. 1,281,280, Oct. 15. The furnace is of the vertical-electrode type and is adapted for melting metals.

**Electric furnace for effecting gas reactions.** A. V. LIPINSKI. U. S. 1,281,604, Oct. 15. The app. is arranged for subjecting gases to an elec. arc flame magnetically spread into sheet form.

**Electric furnaces.** E. L. CROSBY. Can. 187,422, Nov. 12, 1918. An elec. furnace has in combination a rotatable refractory shell, a pair of travel rings engaging thereabout, though variantly spaced therefrom, a series of supporting rollers whereon the travel rings move, thereby turning the shell about a constantly variant axis, means for causing the rotative movement of the rings and electrodes adjustably engaging through the ends of the shell.

**Electric melting furnaces.** T. F. BAILY and F. T. COPE. Can. 187,423, Nov. 12, 1918. An elec. furnace of the resistance type has a heating chamber, a hearth located in the bottom of the chamber, a circular resistance element located above the hearth and a roof so arranged above the resistance element that heat rays radiating upwardly from the resistance element will be reflected upon the hearth while heat rays radiating downwardly will strike directly upon the hearth.

**Calcium cyanamide and phosphorus pentoxide.** E. W. HASLUP. U. S. 1,281,363, Oct. 15. Finely divided phosphate rock mixed with an excess of C is heated to about 1200° while producer gas is passed through the mixt. to drive off the P present and to produce CaO in the residue. The temp. is then raised to about 1500° while the producer gas is still passing through the charge, to form  $\text{CaCN}_2$ . P and P oxides thus obtained are burned to produce  $\text{P}_2\text{O}_5$ .

**Calcium cyanamide.** G. E. COX. U. S. 1,282,381, Oct. 22. In nitrifying  $\text{CaC}_2$  in combustible inner containers held in strong perforated outer containers, the containers are placed in the nitrifying oven before the charge of  $\text{CaC}_2$  is placed in them. Expts. are stated to have shown an increase in fixation of N by this method over the practice of filling the containers elsewhere and then transporting them several hundred feet to the ovens as has been usual previously.

**Electrodeposition of zinc.** G. H. CLEVINGER. U. S. 1,283,077, Oct. 29. Co is removed from  $\text{ZnSO}_4$  electrolytes containing Mn by neutralizing the electrolyte with CaO or ZnO and then pptg. the Co by the addition of an oxidizing agent such as  $\text{KMnO}_4$ . U. S. 1,283,078 specifies the addition of  $\beta$ -naphthol,  $\text{NaNO}_2$  and acid to the electrolyte, forming nitroso- $\beta$ -naphthol which ppts. the Co. Cf. C. A. 12, 1858.

**Electrodeposition of nickel from a nickel-copper anode.** G. A. GUESS. Brit. 118,629, Aug. 14, 1918. A Ni-Cu anode in a  $\text{NiSO}_4$  soln. is maintained in contact with a reagent which forms with  $\text{CuSO}_4$  an insol. Cu compd. and a non-injurious sulfate. The cathode is screened from the reagent and receives a deposit of Ni. Suitable reagents are limestone, CaO, or similar alk.-earths, which give insol. sulfates, or  $\text{NiCO}_3$ , which forms additional  $\text{NiSO}_4$ . The reagent may be kept in suspension, in which case the cathode is in a porous pot. Alternately, pieces of the reagent may be placed in a porous pot around the anode. The electrolyte may be heated to 60-80°.

**Steel from scrap metal.** S. S. WALES. U. S. 1,282,660, Oct. 22. Solid scrap metal is charged into an elec. furnace and molten semi-steel is added to form a coherent mass, which is then melted and refined in the furnace to produce a steel of the desired compn.

**Ferrosilicon.** G. C. FURNESS. U. S. 1,284,645, Nov. 12. Ferro-Si is formed in an elec. furnace by smelting between deeply embedded electrodes a charge containing  $\text{SiO}_2$ , anthracite coal, coke, charcoal or other reducing agent high in C, bituminous coal and Fe ore, scrap steel or other Fe-bearing material, in which the bituminous coal is in a coarser state of division than the other carbonaceous material.

**Shaped castings of iron silicide.** N. G. PETINOT. Can. 187,437, Nov. 12, 1918. Iron and quartz or sand are melted in an elec. furnace with C which reduces the charge so that Fe and Si which are properly proportioned, unite to form a compd. containing 10 to 16% Si. The compd. is poured while molten into molds so as to produce acid-resisting castings. A mixer or holder is attached to the elec. furnace for maintaining the temp. of the molten compd. until sufficient material is produced for a complete casting.

**Electric extraction of zinc.** E. S. BERGLUND. Can. 187,455, Nov. 19, 1918. Zn powder collected in the condenser is subjected to a rubbing and compression action

in the condenser. A screw conveyor in the lower end of the condenser forces the powder through an opening into the receiver.

**Calcium cyanamide.** AKTIEBOLAGET NITROGENIUM. Swiss 77,932, June 17, 1918. In the manuf. of  $\text{CaNCN}$  from  $\text{CaC}_2$  and N gas, the  $\text{CaC}_2$ , which has been intimately mixed with indifferent substances and a catalyzer before being charged into the furnace, is vigorously agitated in the furnace in the presence of N with a view to carrying out the reaction quickly, uniformly, and completely, with prevention of sintering of the mass or dissociation of the  $\text{CaNCN}$  formed.

**Cyanides; nitrides.** A. R. LINDBLAD. Brit. 119,243, Sept. 17, 1918. In the production of cyanides and nitrides in an elec. furnace, the N or nitrogenous gas such as air is drawn into the charge from above by applying suction at a lower level.

**Electrolytic cell for liberating gases from fused electrolytes.** J. L. MALM. U. S. 1,284,403, Nov. 12.

**Electroplating.** M. M. MERRITT. U. S. 1,282,258-9-60, Oct. 22. Lasts for making rubber shoes, or other articles, are formed by treating a wooden core with paraffin, water glass or shellac to waterproof it and with a substance to render it elec. conductive and then electroplating Cu upon it.

**Electroplating.** W. THUM and J. J. MULLIGAN. U. S. 1,283,973, Nov. 5. In directly electroplating the surfaces of Fe, steel and other base metals, the surface to be plated is coated with a protective layer of gelatin and the article is then subjected, in a plating bath, for a short time, to the action of an elec. current of abnormally high d. and then the current d. is reduced to that normally used and continued until a plating of the desired thickness has been formed. The coating with gelatin and preliminary treatment with the current of high d. serve to produce a firmly adhering deposit when Cu or Pb is the coating metal.

**Electroplating with iron.** F. A. SHEPHERD and BRAZIL, STRAKER & CO. Brit. 119,200, Apr. 26, 1918. An Fe-plating electrolyte is made by boiling an aq. soln. containing, for each gal. of  $\text{H}_2\text{O}$ , approx. 2 lbs.  $\text{FeSO}_4$ , 3 oz.  $\text{NH}_4\text{Cl}$ , and 1.5 lbs. divided Fe, there being also added, before or during boiling, 0.25 oz.  $\text{KBr}$ , 0.166 oz.  $\text{NaCl}$ , and 0.166 oz.  $\text{H}_3\text{BO}_3$ . The last three substances are preferably dissolved by boiling and stirring in  $\frac{1}{12}$  of the total  $\text{H}_2\text{O}$  employed, before addition to the boiling Fe soln. The latter soln. should be boiled for a period proportional to the quantities employed; when 12 gals. of  $\text{H}_2\text{O}$  are taken the time required is 10 hrs. The divided Fe is stated to dissolve. Anodes of rolled Fe or mild steel may be used. Steel, Fe, brass, Cu, or other metals may be plated. A pressure of 4 v. and a c. d. of 1 amp. per sq. in. of cathode are suitable.

**Electrolytic refining of bronze anodes.** HÜTTENWERK NIEDERSCHÖNEWEIDE AKT.-GES. VORM. J. F. GINSBERG. Swiss 78,126, June 17, 1918. A soln. containing, besides  $\text{CuSO}_4$ , as electrolyte, up to 12% alkali bisulfate, is used to prevent the formation of stannic acid in the electrolyte.

**Electrolytic production of iron.** A. ESTELLE. Swiss 78,296, July 1, 1918. Hydrated Fe oxide compds. are suspended in a soln. of caustic alkali and the resulting mixt. is electrolyzed.

**Electrodeposition of tin.** H. SARRAMEA. Brit. 119,451, Aug. 13, 1918. See Swiss 76,562 (C. A. 12, 1364).

**Rare-earth metals and chlorine by electrolysis.** ALPHA PRODUCTS CO. Brit. 119,229, Sep. 2, 1918. Electrolysis of a fused salt of Ce or the like is carried on as a continuous run for not less than 8 hrs., say 24-6 hrs., the salt being sufficiently pure to prevent clogging and to permit agglomeration of the metal. Waste material ob-

tained in the gas-mantle industry, and consisting of the oxides or dissolved chlorides of Ce and other metals, may be employed in the production of Ce alloyed with small quantities of La, Di, Er, Th, etc. The oxides may be dissolved in HCl, an excess of the oxides being used. S and P compds. may be removed by Ca or Ba chloride, and Cl-carrying elements of dual valency, such as Fe, and Al, by Ce oxide. The proportion of impurity of each class should be reduced below 3%. The soln. may then be evapd. to dryness. Formation of oxychlorides is prevented by either of two methods. In one method, the dry product is fused in an atm. of HCl gas, which may subsequently be dried for re-use or employed in dissolving Ce oxide or carbonate or the oxide waste above referred to. In the other method, about 15% of NaCl or KCl and a like amt. of  $\text{NH}_4\text{Cl}$ , based on the wt. of rare-earth chlorides, are added before evapn. of the purified solns. After fusion, the proportion of NaCl diminishes below 9%. In this case, the alkali metal chloride accumulates in the electrolytic cell, and may be subsequently dissolved in HCl and purified for re-use. Volatilized  $\text{NH}_4\text{Cl}$  also may be recovered. Fusion is preferably effected in thick pots of cast Fe rich in C and Si, holding preferably more than 100 lb. of salts, which are kept boiling for 20 min. or until evolution of impurities ceases. It is preferable to cast the fused salts in shallow Fe pans or on plates, but they may be transferred directly to the cell. A small quantity, say 5 lb., of salt, preferably prepd. by the second method, is placed in the Fe or clay cell which may be about a foot in diam. and heated first by a gas burner and then by a current of 200 amp. For the first hr. about 1 lb. of the salt is added at intervals of 10-5 min., the current being gradually increased to 900 amp. Subsequently about 2 lbs. of the salt are added every half hr., and the current is increased to 1200-50 amp. during the second hr., being then kept const. A temp. of  $850^\circ$  is maintained. The anode c. d. should not exceed 6-7 amp. per sq. in. for graphite, or 5.5 amp. per sq. in. for C. At the cathode, the c. d. should be about  $\frac{1}{2}$  or  $\frac{1}{4}$  of that at the anode. The anode is accurately adjustable and is maintained at less than an in. from the fused metal of the cathode. A pressure beginning at 12 v. and diminishing to 7 is employed. At intervals of about 2 hrs., the electrolyte is stirred by means of the anode or of a heavy Fe rod. If the electrolyte prepd. by the second method is used throughout, the temp. is raised to  $950^\circ$  during stirring. At the end of the run, say from the 24th to the 27th hr., the cell is heated as strongly as it will stand, by the gas flame and by a current of 15 amp., with stirring every half-hr., to agglomerate the Ce, etc., produced. The charge is finally stirred and allowed to solidify in the cell, which if of cast Fe may then be broken up, as it is attacked by the Ce and cannot be used again with safety. If the electrolyte is prepd. without addition of NaCl, a larger cell and a longer run, say 50-60 hrs., are permissible.

**Sodium perborate.** O. LIEBKNECHT. U. S. 1,281,983, Oct. 15. Na perborate is produced by electrolyzing a soln. of Na borate and  $\text{Na}_2\text{CO}_3$  in the presence of a cathode of Pb, Fe, Ni, Cu, Ag or C or other material which acts *per se* as a catalyzer to the perborate, while protecting the exposed portion of the cathode against the combined action of the electrolyte and air by covering with Pt or by maintaining the entire cathode out of contact with the air.

**Electrolytically depositing metal upon airplane propellers.** M. M. MERRITT. U. S. 1,282,265, Oct. 22. Airplane propellers are coated with a plurality of layers of Cu or other metal, by electrodeposition, with intervening thin layers of grease. U. S. 1,282,268 and 1,282,270 also relate to electrodeposition of metals on propellers.

**Tubular metal articles electrolytically formed.** M. M. MERRITT. U. S. 1,282,269, Oct. 22. In forming manifolds for internal-combustion engines or similar articles, an elec. conductive coating such as graphite is applied to a mold or core, a comparatively coarse-grained layer of Cu is electrolytically deposited on the coated core, this deposit

is amalgamated with Hg and a second layer of Cu of finer grain is then deposited upon the amalgamated surface, to strengthen the article. U. S. 1,282,266 and 1,282,267 relate to manifolds or other articles similarly formed.

**Copper tubes electrolytically formed.** M. M. MERRITT. U. S. 1,282,261, Oct. 22. Mandrels for the electrolytic manuf. of Cu tubes are formed of brass or steel with their surfaces amalgamated with Hg. This treatment serves to facilitate removal of the deposited Cu from the mandrel.

**Forming metal sheets electrolytically.** M. M. MERRITT. U. S. 1,282,262, Oct. 22. In electrolytic formation of sheets of Cu or other metal by deposition of the metal on a rotating cathode, the latter is partially submerged in the electrolyte and rotated at a speed so regulated that a portion of the electrolyte is carried, in a film, over the unsubmerged portion of the cathode. The latter is coated with a thin layer of grease at the beginning of the operation and the mode of operation serves to smooth the grease film and prevent the adherence of occluded H<sub>2</sub> to the cathode.

**Copper sheets electrolytically produced.** M. M. MERRITT. U. S. 1,282,263, Oct. 22. In forming Cu sheets by electrodeposition upon a rotating cylindrical mandrel, the formation of irregular deposits on or near the edges of the plates is prevented by placing a conductor adjacent to the edges of the cathode and passing an elec. current through this conductor. U. S. 1,282,264 relates to the formation of Cu sheets on a rotating mandrel after first winding string coated with shellac or other non-conducting material upon the mandrel in the form of a helix to facilitate tearing the Cu sheet into an elongated strip after deposition.

**Electrolytic recovery of copper from ores.** A. A. LOCKWOOD. U. S. 1,282,892, Oct. 29. An acid pulp is formed of roasted Cu sulfide ore mixed with H<sub>2</sub>O or acid leaching soln. and this pulp, agitated and aerated by injecting air into it, is led into an electrolytic vessel and Cu is electrolytically deposited. An insol. anode is used, and air is introduced into the lower part of the mixt. undergoing electrolytic treatment, to prevent settling of the suspended solids in the mixt. The pulp from the electrolytic vessel is then returned to the bulk of acid pulp and the cycle of operations is repeated.

**Electrolytic production of caustic alkali.** H. H. DOW. U. S. 1,284,618, Nov. 12. In causticizing alkali metal chloride solns., there is added to the anode chambers of a plurality of sep. electrolytic cells of the diaphragm type a quantity of the soln. greater than the diaphragms can transmit by percolation and the excess soln. is drawn off after treatment and passed successively through all the cathode chambers in the series of cells. This manipulation of the electrolyte tends to minimize consumption of elec. energy, anode erosion and formation of undesired by-products.

**Separating suspended matter from gases.** L. BRADLEY. Brit. 119,236, June 21, 1917. In the elec. pptn. of suspended matter from gases, the cond. of the gases is improved by adding an agent such as H<sub>2</sub>O, steam, or H<sub>2</sub>SO<sub>4</sub> vapor. The gases may be maintained under pressure to prevent inward leakage of air. The sepn. of particles such as soot may be rendered more effective by wetting them. When the sepd. particles are deliquescent as in the case of potassiferous blast-furnace dust, the temp. should be kept high enough to keep the insulators dry.

**Treating used electrolyte of primary batteries.** S. H. SHEIB. U. S. 1,281,857, Oct. 15. Used alk. electrolyte of primary batteries is collected in a drum, allowed to remain quiescent until oils have risen to the surface, and the soln. is drawn off from beneath the oils and electrolyzed to recover the Zn.

**Incandescent lamps with tungsten filaments.** F. W. GILL. U. S. 1,284,648, Nov. 12. The light-giving portion of W filaments of incandescent elec. lamps is coated with NaCl in insufficient amt. to produce discoloration of the bulb or to cause appre-

cable attack on the exposed metal in the lamp when the latter is in use, and the lamp is assembled and sealed and the temp. of the coated filament is raised to incandescence to drive off the NaCl from the filament. This treatment serves to diminish obscuration of the bulb.

**Ductile tungsten.** C. A. PFANSTIEHL. U. S. 1,282,122, Oct. 22. Ductile W is produced by compressing finely powdered W to a d. greater than 15.5 (preferably about 16.02) and then fusing the particles together electrically in an atm. of H while supported in a cradle of ductile W through which the elec. current is passed.

LOUIS DERR.

**Examination of organic developing agents.** H. T. CLARKE. *J. Ind. Eng. Chem.* 10, 891-5(1918).—Details of procedure for identification and quant. detn. of the commoner photographic developing agents and some typical analyses of metol developers are given.

L. DERR.

**Multicolor photographic film.** J. E. THORNTON. U. S. 1,281,714, Oct. 15. A celluloid or other transparent support is coated with an adhesive substratum, finely subdivided figures are mechanically printed upon it to form a screen for color photography, an adhesive layer is applied over the screen with an overlying coating of panchromatic gelatin-AgBr emulsion with a yellow filter interposed between the multi-color screen and panchromatic emulsion.

## 6. INORGANIC CHEMISTRY.

H. I. SCHLESINGER.

**Gallium.** L. M. DENNIS AND J. A. BRIDOMAN. *J. Am. Chem. Soc.* 40, 1531-61 (1918).—The crude material employed was about 35 g. of an alloy of Ga and In containing about 8% In, 1% Zn and traces of Cd and Cu. By ocular observation of the spark spectrum 0.0046 mg. Ga and 0.0013 mg. In could be detected in the solns. of the chlorides; both principal lines were visible when 0.014 mg. Ga and 0.0065 mg. In were present. Large excess of either element was found to impair but slightly the delicacy of these tests. Traces of Zn could not be detected by this method; by photographing the arc spectra of mixtures of the chlorides Zn and In could be detected when the weight of the Zn and of the In is only 0.005% of the weight of the Ga present. By fractional electrolysis of slightly acid solns. of the sulfates, Zn could be entirely removed and In nearly completely. Fractional distn. of the chlorides gave Ga containing less than 0.005% of In or Zn. Methods were devised for the analysis of mixtures containing Ga, In, Zn and Al. Two new Ga salts were prepd.,  $\text{Ga}_2(\text{SeO}_4)_3 \cdot 16\text{H}_2\text{O}$  and  $\text{CsGa}(\text{SeO}_4)_2 \cdot 12\text{H}_2\text{O}$ . One part  $\text{Ga}_2(\text{SeO}_4)_3 \cdot 16\text{H}_2\text{O}$  dissolves in 1.74 parts water at 25°; 1 part of the Cs alum in 24.1 parts water. One part  $\text{NH}_4\text{Ga}(\text{SO}_4)_2 \cdot 12\text{H}_2\text{O}$  dissolves in 3.24 parts of water; in 4600 parts of 50% EtOH; in 11400 parts 70% EtOH at 25°. One part  $\text{CsGa}(\text{SO}_4)_2 \cdot 12\text{H}_2\text{O}$  dissolves in 66.2 cc. water; in 25800 parts 50% EtOH; in 28000 parts 70% EtOH, at 25°.

A. R. MIDDLETON.

**Preparation of certain organic chlorostannites and chlorostannates.** J. G. F. DRUCE. *J. Chem. Soc.* 113, 715-8(1918); cf. C. A. 12, 1622.—These new salts were prepd. from HCl solns. of the component halides: *diethylamine chlorostannite*,  $(\text{NH}_4)_2\text{H}_2\text{SnCl}_4$ , very deliquescent, m. 58°; *o-toluidine chlorostannite*,  $(\text{C}_7\text{H}_7\text{N})_2\text{H}_2\text{SnCl}_4$ , fine silky needles, sol. in cold water, m. 164°; *o-toluidine chlorostannate*,  $(\text{C}_7\text{H}_7\text{N})_2\text{H}_2\text{Sn}$

$\text{Cl}_4\text{H}_3\text{O}$ , pale pink needles, decompn. begins at  $210^\circ$ ; *methylaniline chlorostannite*,  $\text{C}_7\text{H}_7\text{N}.\text{HSnCl}_4$ , stout, colorless prisms, sol. in water and  $\text{EtOH}$ , not in  $\text{CHCl}_3$ , m.  $106^\circ$ ; *methylaniline chlorostannate*,  $(\text{C}_7\text{H}_7\text{N})_2.\text{H}_2\text{SnCl}_4$ , colorless crystals, sol. in water, not hydrolyzed even when boiled, m.  $251^\circ$  (decompn.); *m-phenylenediamine chlorostannite*,  $\text{C}_6\text{H}_4(\text{NH}_2)_2.2\text{HSnCl}_4$ , silky prisms, m.  $128^\circ$ , sol. in water; *m-phenylenediamine chlorostannate*, colorless crystals, m.  $265^\circ$  (decompn.), sol. in cold water, not hydrolyzing unless heated; *p-phenylenediamine chlorostannite*, opaque, white crystals, sol. in cold water, readily hydrolyzed on slight warming, m.  $270^\circ$  (decompn.); *p-phenylenediamine chlorostannate*, pearly plates, sol. in cold water, ppt. forms on boiling, m.  $230^\circ$ ; *benzylamine chlorostannite*,  $\text{C}_7\text{H}_7\text{N}.\text{HSnCl}_4$ , silky crystals, soften at  $95^\circ$ , decompn. at  $210^\circ$ ; *benzylamine chlorostannate*,  $(\text{C}_7\text{H}_7\text{N})_2.\text{H}_2\text{SnCl}_4$ , shining flakes, m.  $112^\circ$ ; *p-methylbenzylamine chlorostannite*,  $\text{C}_8\text{H}_{11}\text{N}.\text{HSnCl}_4$ , m.  $107^\circ$ , slowly sol. in water, soln. soon decomps.

A. R. MIDDLETON.

Separation of traces of copper from solution. J. E. SAUL AND D. CRAWFORD. *Analyst* 43, 348(1918).—Dissolve 0.1% of quinosol in the aq. soln. containing Cu and let stand overnight. A voluminous ppt. of the Cu salt is obtained, in yellowish flocculent masses consisting of bundles of delicate needles sol. in dil. HCl. A soln. of  $\text{CuSO}_4$  containing 0.0002% Cu yielded a distinct ppt. which could be easily collected. Salts of other common metals did not yield ppts. in high dilns., although one was obtained from a strong soln. of a  $\text{Hg}^{++}$  salt.

F. W. SMITHER.

The behavior of phosphates at the anode. FR. FICHTER AND JAKOB MÜLLER. Univ. Basel. *Helvetica Chimica Acta* 1, 297-305(1918).—Schmidlin and Massini obtained two perphosphoric acids by the action of  $\text{H}_2\text{O}_2$  on  $\text{P}_2\text{O}_5$ , *monoperphosphoric acid* and *perphosphoric acid*, to which they gave the formulas  $\text{H}_2\text{P}_3\text{O}_8$  and  $\text{H}_4\text{P}_3\text{O}_{10}$ . F. and M. develop a method for making these acids electrolytically. With Pt electrodes and a soln. of K or  $\text{NH}_4$  phosphate containing  $\text{CaF}_2$  and  $\text{K}_2\text{CrO}_4$  yields of about 30% can be obtained. The chromate prevents reduction of the per-acids formed. The  $\text{H}_2\text{P}_3\text{O}_8$  and  $\text{H}_4\text{P}_3\text{O}_{10}$  are sepd. by their rates of oxidation of a  $\text{H}_2\text{SO}_4$  soln. of KI. The first causes instant pptn. of I; the second only on standing for 24 hours. For a 2 M soln. of  $\text{K}_2\text{HPO}_4$  the soln. should be 4N in KF and contain 0.32 g.  $\text{K}_2\text{CrO}_4$  per l. The yield is better at low temps., being 10% at  $25^\circ$ ; and 23% at  $5^\circ$ , which is the best temp. Low current density increases the yield, and 0.010 amp./cm<sup>2</sup> gives 34% yield, calcd. on the basis of the current. The condition of the Pt surface has great influence on the yield, as has also the ratio of acid to base. With  $\text{NH}_4$  phosphate the yield is not so good, but with  $\text{Rb}_2\text{HPO}_4$  35% of the theoretical is obtainable. The free acid and the sodium salt gave poor results.

F. C. HORT.

The rate of oxidation of nitric oxide. E. BRINER AND E. FRIDÖRI. *Helvetica Chim. Acta* 1, 181-5(1918); *J. chim. phys.* 16, 279-321(1918).—The oxidation of NO, first believed to be quite simple, was shown by numerous expts. to be very complex. The following reactions may occur in the oxidation: (1)  $2\text{NO} + \text{O}_2 = 2\text{NO}_2$ , (2)  $4\text{NO} + \text{O}_2 = 2\text{N}_2\text{O}_3$ , (3)  $\text{NO} + \text{NO}_2 = \text{N}_2\text{O}_3$ , (4)  $2\text{N}_2\text{O}_3 + \text{O}_2 = 4\text{NO}_2$ , (5)  $2\text{NO}_2 = \text{N}_2\text{O}_4$ . Obviously, the equil. of the system will be controlled by the reaction whose rates are slowest, and these are, therefore, of greatest importance. A known mixt. of NO and air is passed into the oxidation chambers, which consist of a series of glass tubes in a thermostat. Stopcocks at various points enable a measurement of the progress of oxidation at different sections in the path of gas flow to be made. A first coil cooled to  $-80^\circ$  by  $\text{CO}_2$  snow and alc., condenses out  $\text{NO}_2$ ,  $(\text{N}_2\text{O}_4)$  and  $\text{N}_2\text{O}_3$ . A second coil immersed in liquid air retains the NO. After this sepn. is effected the contents of the first coil are driven into  $\text{H}_2\text{SO}_4$  which is then passed into a Lunge nitrometer. This detn. gives the amt. of NO transformed into  $\text{NO}_2$ ,  $(\text{N}_2\text{O}_4)$  and  $\text{N}_2\text{O}_3$ . The contents of the second coil are evapd. and treated with  $\text{O}_2$  to render them sol. in  $\text{H}_2\text{SO}_4$  and then

analyzed in a nitrometer. In detg. the order of the reaction no single phase of the process was considered but the process in general, so as to det. the order av. and characteristic of the process. Calcns. showed that the order of the reaction varied as it progressed, the av. value being about 2. The rate of the reaction was shown to increase with decrease in temp. This unusual behavior, which was previously noted by Bodenstein and Meinecke, may be used to advantage in improving the recovery of oxides of N. The av. value obtained for the order of the reaction is reconciled with the third order equation for the reaction rate:  $dx/dt = kC^2NOCO_2$ . Since the  $O_2$ , being in large excess, may be considered of const. concn., the term  $CO_2$  drops out and the equation becomes of the second order. The oxidation of NO to  $N_2O_4$  and  $N_2O_3$  may then be expressed as  $dx/dt = k(A - x)^2$  where  $A$  is the initial concn. of NO and  $x$  the fraction transformed in the time  $t$ . This relation gives us a means of calcg. the time required for a given oxidation and *vice versa*. An examn. of the integrated expression  $kt = x/[A(A - x)]$  shows that the rate of reaction is proportional to the concn.

## 7. ANALYTICAL CHEMISTRY.

R. G. R. ARDAGH.

Analysis of mixtures containing gallium, indium, zinc and aluminium. L. M. DENNIS AND J. A. BRIDGMAN. *J. Am. Chem. Soc.* 40, 1549-57(1918).—Two samples are prepd. for analysis, the one for the detn. of Zn, Ga and Al contg. not more than 0.1 g. of Zn, and the other for the detn. of In, Ga and Al which should not contain more than 0.1 g. of In. Ga and Al are detd. in the sample in which each is present in the most suitable amt. In the 1st sample Zn is detd. by double pptn. with  $K_2Hg(SCN)_4$ . To detn. In and Ga in the filtrate, the Hg is removed as HgS, the In by double pptn. with excess NaOH and the remaining soln. is boiled with  $Na_2SO_3$  in slightly acid soln. to ppt. Ga and Al as hydroxides. In the absence of Al, the ppt. is dissolved in HCl and the  $Ga(OH)_3$  repptd. by  $Na_2SO_3$  and weighed as  $Ga_2O_3$ . If Al is present, Ga and Al are sepd. by treating the solp. of the combined hydroxides in HCl with gaseous HCl in the presence of a vol. of ether equal to that of the aq. soln. The hydrated  $AlCl_3$  is redissolved in  $H_2O$  and Al detd. as usual. The remaining soln. is freed from excess HCl and from ether and the Ga detd. as described above. In sample 2, In is detd. by double pptn. with excess of NaOH and repptn. with  $NH_4OH$  and weighing as  $In_2O_3$ ; the Zn is removed by addition of  $K_2Hg(SCN)_4$ ; after removal of Hg, Ga and Al may be detd. as in sample 1.

A. R. MIDDLETON.

Critical study of the Carnot method for determination of potassium salts. CAROLINA ETILE SPAGAZZINI. *Univ. La Plata. Anales soc. quim. Argentina* 6, 196-209(1918).—Turbidity was noted in many instances when alc. was added to the Carnot reagent (double thiosulfate of Bi and Na or Ca); this turbidity disappears when HCl is added

and may be prevented by adding the required amt. of HCl to the Carnot reagent. The amt. of HCl required to produce the optimum acidity of the Carnot reagent should be detd. by means of a 0.1 *N* KCl test soln. at the time each lot of BiCl<sub>3</sub> reagent is prep'd.; the proportion of HCl required varies with each lot of BiCl<sub>3</sub> reagent owing to the variation in d. of the acid used for transforming the subnitrate into BiCl<sub>3</sub>, the accuracy of measurement of the acid, etc. The accuracy of the Carnot method was tested against a 0.1 *N* KCl soln.; the original Carnot technic as well as the procedures indicated by Grandeau and Fresenius were followed. Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> was used in some cases and CaS<sub>2</sub>O<sub>3</sub> in others. The results were generally much too high. The variation in results is attributed to a no. of variable factors such as acidity of the reagent, temp. at which formation of the K-Bi compd. occurs, concn. of the K salt to be detd., compn. of the system required for pptn. of the K-Bi compd., etc. The following procedure is recommended for pure, dil. solns. of KCl and KNO<sub>3</sub>: Mix at 12-14° 2 cc. BiCl<sub>3</sub> soln., 1 cc. Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> or CaS<sub>2</sub>O<sub>3</sub> soln. (with pure solns. the result is the same when the Carnot reagent is prep'd. with equal vols. of BiCl<sub>3</sub> and thiosulfate solns.), the required amt. (dild. in 10 cc. alc.) of HCl (of 1.19 d. dild. 1:2) for optimum acidity, and 100 cc. alc. Add drop by drop 2 cc. of 0.1 *N* KCl soln., agitate vigorously, allow to stand 15 mins. at 12-14°, wash the ppt. 3 times by decantation with 5 cc. each of concd. alc. and 2-3 times on a filter with 10 cc. each of alc. Dissolve the ppt. in hot H<sub>2</sub>O, dil. to 500 cc. with distd. H<sub>2</sub>O, add 5 drops 1:2 HCl, 1-2 g. KI, 2 cc. of starch paste and titrate with 0.1 *N* I soln. This method, when applied to KNO<sub>3</sub>, would be slightly modified by adding the KNO<sub>3</sub> soln. drop by drop to the acidulated Carnot reagent at 12-14°, agitating vigorously, then adding the 100 cc. of 96% alc. and again agitating vigorously. Results obtained with K<sub>2</sub>SO<sub>4</sub> were always much too low. The method gave good results with a mixt. of KCl and CaCl<sub>2</sub> when the former was present in excess and inaccurate results when the latter predominated. The method was satisfactory for a mixt. of KCl and MgCl<sub>2</sub> provided there was not a great excess of the latter. When applied to a mixt. of KCl and NaCl the method gave satisfactory results provided the KCl was either present in excess or was present in the same proportion as NaCl; it was not applicable to solns. in which NaCl predominated over the KCl. The method cannot, therefore, be applied with success to unknown mixts. and its use is restricted to certain pure solns. S. gives tabulated data showing the results obtained with KCl solns. of known strength when the acidity of the reagent (at both room temp. and 12°), the temp., the period of standing, and the acidity of the aq. soln. of Bi and K thiosulfate were each varied in turn, the remaining conditions being kept const. in each instance. These data also show in detail the results obtained at different temps. with various mixts. of KCl and CaCl<sub>2</sub>, KCl and MgCl<sub>2</sub>, KCl and NaCl.

H. S. PAINE.

The estimation of potash. T. STEEL. *Analyst* 43, 348-9(1918).—Treat the HCl soln. (obtained by whichever method may best suit) containing Fe, Ca, Mg, etc., but freed from SiO<sub>2</sub>, at once with excess of H<sub>2</sub>PtCl<sub>6</sub>, and evap. on a H<sub>2</sub>O-bath. Cool, take up with a mixt. of alc. 76, ether 13, H<sub>2</sub>O 11, filter, and wash with the same mixt. till free from sol. Pt. Wash the residue on the filter with boiling H<sub>2</sub>O to dissolve all K<sub>2</sub>PtCl<sub>6</sub>, receiving the filtrate in a beaker. Heat the soln. to boiling, add an excess of Na formate, boil a few mins., add an excess of HCl, and heat until the reduced Pt is thoroughly flocculated; collect the Pt on a filter, wash, ignite, and weigh; Pt × 0.4826 = K<sub>2</sub>O. S. states that the method is rapid and accurate, but reports no results. Constituents other than K are estd. in a sep. portion of the sample or soln. (cf. Blount, C. A. 12, 1371; Dyer, *J. Chem. Soc.* 65, 140 (1894)).

F. W. SMITHER.

Assay supplies and the utilization of South African materials in assay offices. T. G. MARTYN. *J. Chem. Met. Soc. S. Africa* 19, 18-22(1918).—Discussion.

Cupels with cement bottoms were found to be good. The mold is first filled with cement, pressed moderately, then filled up with cupellite (bone ash?) and pressed as hard as possible. Crucibles of coarse texture have more endurance when fired. When fine-grained and hard-burned they tend to fissure in use. Necessity for repeated re-use has shown the av. life to be about 18 fusions per crucible. The life is shortened by basic charges (borax, etc.) or by bedding in glowing fuel. A borax substitute "fluxite" is practically, pulverized fluorspar, 10% less should be used. M. believes that in the fusion, this forms fluosilicate, rendering the charge more basic, *e. g.*,  $2\text{CaF} + \text{SiO}_2 = \text{SiF}_4 + 2\text{CaO}$ , the  $\text{SiF}_4$  going to form fluosilicate. When Ag occurs in more than trace in litharge it is never evenly distributed. For assays of low-grade material (residues, tailings, etc.) the Pb button aimed for should be 50 or 60 g.; 20 g. is dangerously low. To get  $\text{CuCl}$ , M. adds a concd. soln. of  $\text{Na}_2\text{SO}_4$  to a mixt. of  $\text{CuSO}_4$  and  $\text{NaCl}$  in soln. in commercial  $\text{HCl}$ . The  $\text{HNO}_3$  used in parting can be economized by redistg. The first run of weak acid might be reserved for cleaning out the still subsequently. Soda ash containing carbonaceous matter is frequently supplied to assay laboratories. Dissolving, filtering, and recalcining may be necessary for some purposes. The necessary heat for parting work can be obtained most economically by having an extra muffle door, which when heated up can be propped up suitably and made to serve as a "hot plate" on which to place an aluminium frying pan carrying the parting capsules.

E. WALLER.

**Estimation of boric acid by the use of manna.** L. E. ILES. *Analyst* 43, 323 (1918).—Manna can be used satisfactorily in the estn. of  $\text{H}_3\text{BO}_3$ . A fresh soln. (waxy portions of material to be discarded), is made for each detn.; it is neutralized and added in the same way as glycerol; usually 5 g. in soln. are equiv. to about 25 cc. 80% glycerol. Analyses of  $\text{H}_3\text{BO}_3$ , boric acid ointment, and borax gave 100.0, 10.0 and 99.9, resp., by this method; corresponding figures obtained using glycerol were 100.0, 9.9 and 99.8.

H. M. LANCASTER.

**The estimation of thiosulfuric, sulfurous, trithionic and sulfuric acids in a mixture.** O. BILLETER AND B. WAVRE. University Neuchatel. *Helvetica Chim. Acta* 1, 174–80 (1918).—It is possible to est.  $\text{H}_2\text{SO}_3$  and  $\text{H}_2\text{S}_2\text{O}_3$  in presence of each other, by first detg. both iodometrically, and then detg.  $\text{H}_2\text{SO}_3$  by a method based on the reaction  $\text{Na}_2\text{S}_3 + \text{Na}_2\text{SO}_3 = \text{Na}_2\text{S} + \text{Na}_2\text{S}_2\text{O}_3$ . This change takes place rapidly near the boiling temp. and is further accelerated by addition of  $\text{NH}_4\text{Cl}$ . The persistence of the yellow color of the reagent serves as a satisfactory end-point. To prep. a *N* soln. of  $\text{Na}_2\text{S}_3$ , sat. 500 cc. *N*  $\text{NaOH}$  with  $\text{H}_2\text{S}$ , remove excess gas under diminished pressure, add an equal vol. *N*  $\text{NaOH}$ , then dissolve in the soln. in the cold, 16 g. S crystallized from  $\text{CS}_2$ . To the flask contg. the soln., join a buret by means of a syphon, and connect both with a gas holder of N for displacing air from the system. Standardize the  $\text{Na}_2\text{S}_3$  soln. gravimetrically. Measure 20 cc. into a soln. contg.  $\text{AcONa}$  and a slight excess of  $\text{AcOH}$ , expel  $\text{H}_2\text{S}$  by boiling in a current of  $\text{CO}_2$ , collect the S on a filter of tared glass wool, dry *in vacuo* over  $\text{H}_2\text{SO}_4$  and weigh. The small amt. of thiosulfate always present in the soln. of  $\text{Na}_2\text{S}_3$  can be detd. iodometrically and the necessary correction applied. The greater the diln., the more rapid is the titration and the more definite is the end point. However, it is not advisable to have more than 100 cc. per 5 cc. reagent. Under these conditions each 100 cc. should contain 5 cc. 2 *N*  $\text{NH}_4\text{Cl}$  and should be slightly alk. (alkalinity equiv. to 4 cc. *N*  $\text{Na}_2\text{CO}_3$  per 50 cc.). A current of  $\text{CO}_2$  should be kept passing over the surface of the liquid during the titration which should require less than 10 min., especially if the approx. titration has been ascertained by previous expt. If trithionate is present, the situation is more complicated. Trithionate is not acted upon by I in the cold but it is converted into thiosulfate by  $\text{Na}_2\text{S}$ , thus:  $\text{Na}_2\text{S}_2\text{O}_6 + \text{Na}_2\text{S} \rightarrow 2\text{Na}_2\text{S}_2\text{O}_3$ . This reaction is slow in the cold, but is rapid at higher temp.;

in presence of  $\text{Na}_2\text{S}_2$ , S is pptd. Heat a dil. soln. with a slight excess of  $\text{Na}_2\text{S}$  or  $\text{Na}_2\text{S}_2$  (in presence of  $\text{NH}_4\text{Cl}$ ) for several mins. near the boiling point, add  $\text{AcONa}$  and a slight excess  $\text{AcOH}$ ; heat for 15 min. in a current of  $\text{CO}_2$ , then titrate with 0.1 N I. Results are good; 0.1785 g.  $\text{K}_2\text{S}_2\text{O}_8$  requires 13.25 cc. 0.1 N I. In the case of a mixt. of sulfite and trithionate, the  $\text{Na}_2\text{S}_2$  produces both changes simultaneously  $\text{Na}_2\text{SO}_3 + \text{Na}_2\text{S}_2\text{O}_3 + \text{Na}_2\text{S}_2 \rightarrow 3\text{Na}_2\text{S}_2\text{O}_3$ . If trithionate is present in excess, it is shown by a turbidity due to S which appears after the sulfite is consumed. The turbidity does not interfere with the end-point as the yellow color of the reagent is readily observed. A mixt. for analysis contained 5 cc.  $\text{Na}_2\text{S}_2\text{O}_3$  soln. corresponding to 4.80 cc. 0.1 N I; 2 cc.  $\text{Na}_2\text{SO}_3$  soln. corresponding to 9.19 cc. 0.1 N I and to 1.84 cc.  $\text{Na}_2\text{S}_2$ ; 0.1337 g.  $\text{K}_2\text{S}_2\text{O}_8$  corresponding to 9.88 cc. 0.1 N I. Titration of this mixt. was described; it required 1.90 cc.  $\text{Na}_2\text{S}_2$  and 24.00 cc. 0.1 N I. An alternative method for trithionate is based on the titration of the residual I after heating with excess I soln. under pressure. This follows the titration of sulfite and thiosulfate in the cold. The tetrathionate from the latter is then changed to sulfate, as is the trithionate. The principle appears to be sound but there are many sources of error. Another procedure for detg. trithionate employs the action of heat;  $\text{H}_2\text{S}_2\text{O}_6 \rightarrow \text{H}_2\text{SO}_4 + \text{SO}_2 + \text{S}$ . Acidify the soln. by adding  $\text{HCl}$ , heat near the boiling point in a current of  $\text{CO}_2$  until  $\text{SO}_2$  is all expelled (end of operation detected by dipping the end of the delivery tube into dil. I soln.), filter off the S and ppt. the  $\text{H}_2\text{SO}_4$  with  $\text{BaCl}_2$ . Investigation showed that the ppt. thus obtained contained 97.9–97.5% of the trithionate which was converted into sulfate. In presence of  $\text{H}_2\text{SO}_3$  and  $\text{H}_2\text{S}_2\text{O}_3$  the loss is more or less compensated for by the unavoidable oxidation of the  $\text{H}_2\text{SO}_4$ . If  $\text{H}_2\text{SO}_4$  is also present, it is of course pptd. A known mixt. containing 0.3457 g.  $\text{K}_2\text{SO}_4$  (1.982 millimol.) with 0.1315 g.  $\text{K}_2\text{S}_2\text{O}_8$  (0.486 millimol.) also 1.813 millimol.  $\text{Na}_2\text{S}_2\text{O}_3$  and 2.445 millimols.  $\text{Na}_2\text{SO}_3$ , gave on analysis 2.485 millimols. trithionate and sulfate (100.7% theor.). In dealing with a mixt. of all four acids, oxidize with Br water, ppt. with  $\text{BaCl}_2$  and thus obtain total S as sulfate. The detns. outlined above then complete the data for calcn. of the four constituents. In titrating trithionate by I and  $\text{Na}_2\text{S}_2$ , and detg.  $\text{H}_2\text{SO}_4 + \text{H}_2\text{S}_2\text{O}_3$  gravimetrically,  $\text{H}_2\text{SO}_4$  is thus obtainable by difference. The detn. of total S serves as a check.

H. M. LANCASTER.

**Modification in technic of the Fischer reaction for hydrogen sulfide.** LUCIANO P. J. PALET AND AMANCIO FERNANDEZ. *Anales soc. quim. Argentina* 6, 49–51 (1918).—To a small amt. of  $\text{PhNMe}_2$ , add 2 cc.  $\text{H}_2\text{O}$ , 3–4 drops of a 1% aq.  $\text{NaNO}_2$  soln. and 5 drops of 10%  $\text{HCl}$ . Agitate the mixt. and then neutralize with a cold satd.  $\text{Na}_2\text{CO}_3$  soln. Ext. the nitroso deriv. with  $\text{Et}_2\text{O}$  and to the latter, after decantation, add a small amt. of Zn and several drops of concd.  $\text{HCl}$ . When the green color disappears (completion of reduction) decant the supernatant  $\text{Et}_2\text{O}$ , dil. the remaining liquid with 2 cc.  $\text{H}_2\text{O}$ , add the substance which is to be tested for  $\text{H}_2\text{S}$  and treat the mixt. with concd.  $\text{HCl}$  and  $\text{FeCl}_3$  according to Fischer's technic; formation of methylene blue indicates a positive result. The reaction may be made more perceptible by extg. the methylene blue with alc. If  $\text{HCl}$  is not present in sufficient amt. there is produced a red color due to action of aminodimethylaniline and  $\text{FeCl}_3$  in slightly acid soln.; for this reason it is better to add 1/10 rather than 1/40 by vol. of  $\text{HCl}$ . By this simplification of technic *p*-aminodimethylaniline may be prepd. as needed and the necessity for keeping it in hermetically closed containers is avoided.

H. S. PAINÉ.

**Arsenotungstic and arsenotungstomolybdic complexes as reagents of phenolic amines.** LUIS GUGLIAMELLI. *Anales soc. quim. Argentina* 6, 185–95 (1918).—The action of these reagents (cf. C. A. 12, 664) on phenolic amines containing the groups  $-\text{NH}_2$ ,  $=\text{NH}$  and  $\equiv\text{N}$  was investigated. In the case of the arsenotungstic reagent the characteristic blue color (due to lower oxides of W and Mo) in alk. soln. was ob-

tained with compds. which contain the united groups  $\text{NO-NH}_2$ ,  $\text{H}_2\text{N-NH}_2$ ,  $\text{RHN-NH}_2$ ,  $\text{NHR-NHR}$  or  $\text{NHR-OH}$  (as in hydroxylamine, hydrazine, phenylhydrazine, hydrazobenzene, phenylhydroxylamine) and also with compds. which contain these groups sepd. but attached directly to  $\text{C}_6\text{H}_4$ , naphthalene, purine and pyrazole nuclei (as in *m*- and *p*-phenylenediamine, *p*-aminophenol, etc.). The positive reaction obtained with  $\alpha$ -naphthylamine, aminoantipyrine, pyrimidine, caffeine and purine derivs. such as xanthine, guanine and uric acid in spite of the fact that these compds. do not fulfill the above conditions is attributed to a tautomeric transformation of the mol. or to the influence of the configuration of the (electronegative) nucleus on the reducing action of the groups in question. The arsenotungstomolybdic reagent gave a positive reaction in all cases in which a positive reaction was obtained with the arsenotungstic reagent. In addition the former reagent is sensitive to the presence of a single  $-\text{NH}_2$ ,  $=\text{NH}$  or  $\equiv\text{N}$  group; thus, a positive reaction was obtained with  $\text{PhNH}_2$ ,  $\beta$ -naphthylamine, aminobenzoic acid, tyrosine, aminoacetophenone, etc. A negative reaction was obtained with substituted phenols, while the presence of free phenolic OH groups considerably increased the reducing action of these compds. on the arsenotungstomolybdic reagent; thus, no trace of color was obtained with *p*-phenetidine. The reducing action of phenolic amines is also greatly reduced or even destroyed by the introduction of electronegative groups. Thus, the presence of the acid groups  $\text{SO}_3\text{H}$ ,  $\text{AsO}(\text{OH})_2$  and  $\text{NO}_2$  in sulfanilic acid, atoxyl and nitroaniline, resp., caused the practical disappearance of reducing action. While a negative reaction was obtained with *p*-phenetidine, a positive reaction was obtained with its isomer ethyl-*p*-aminophenol, this being due in the latter instance to the presence of  $=\text{NH}$  and free OH. A distinctly positive reaction was obtained with thiourea and thiosinamine; it is assumed in each case that tautomeric transformation resulted in the formation of SH groups with active reducing action.

## 8. MINERALOGICAL AND GEOLOGICAL CHEMISTRY.

---

EDGAR T. WHERRY AND J. H. BOWER.

The numerical relations between the Et curve and the E $\lambda$  curve of the Eifel sandine. S. KÖZU. *J. Geol. Soc. Tokyo* 25, 43-5(1918). S. G. GORDON.

The crystallography and nomenclature of hollandite. L. LEIGH FERMOR. *Rec. Geol. Survey India* 48, 103-20(1917).—Hollandite crystals up to 2 inches long from the Kajhlongri mine, Jhabua State, Central India, were examd. and found to be tetragonal pyramidal,  $c = 0.2039$ , with the principal forms  $m$  (110),  $a$  (100),  $k$  (210),  $p$  (111), and  $q$  (331), and about 57 more or less indefinite forms. Hollandite is considered to be the crystalline form of psilomelane, and a manganate, corresponding to the formula  $\text{H}_2\text{MnO}_6$ , probably a member of the scheelite group. Romanéchite of Lacroix, and possibly coronadite are identical with hollandite. Fermor suggests that the letter  $\alpha$  be prefixed to indicate crystalline phases of amorphous minerals, and the prefix  $\kappa$  to indicate colloidal phases of crystalline minerals.

S. G. GORDON.

**Fayette Co., Texas, meteorite finds of 1878 and 1900 and the probability of their representing two distinct falls.** GEORGE P. MERRILL. *Proc. U. S. Nat. Museum* 54, 557-61(1918).—A re-exam. of thin sections of these stones shows a striking difference in the physical conditions of the two prevailing silicates, the olivine and enstatite. Also the sections of the 1900 stone show numerous chondrules composed wholly of the polysynthetically twinned pyroxene, none of which appear in any of the slides examd. of the 1878 find. The 1900 stone is more deeply oxidized than the 1878, suggesting an earlier fall. The location of the 1900 find is not in line with that of the three fragments of the 1878 find. The name Cedar, Fayette Co. is proposed for the 1900 stone.

**War-time mineral activities in Washington.** EDSON S. BASTIN. *Econ. Geol.* 13, 524-37(1918).—An outline of what has been done by the Joint Information Board on Minerals and Derivatives in regard to problems of available supplies, domestic and foreign reserves, requirements, price and cost of production, uses, and consumption.

A. B. PECK.

**Mineral resources of Alaska. Report on progress of investigations in 1916.** ALFRED H. BROOKS, *et al.* U. S. Geol. Survey, *Bull.* 662, 458 pp.(1918).—This volume, the 13th of a series of annual bulletins treating of the mining industry of Alaska, contains, beside the administrative report and general review by A. H. BROOKS, papers by H. M. EAKIN (2), B. L. JOHNSON (2), J. B. MERTIE, JR. (4), THEODORE CHAPIN, G. H. CANFIELD, F. H. MOFFIT, S. R. CAPPS, G. L. HARRINGTON, R. M. OVERBECK, and A. G. MADDREN one each. *Au*, *Ag*, *Cu*, *Sn*, *Sb*, *Pb*, and coal mining operations are described, also the developments or prospects for *Pt*, *W*, petroleum, marble, gypsum, and water powers.

L. W. RIGGS.

**Manganese deposits in Madison Co., Montana.** J. T. PARDEE. U. S. Geol. Survey, *Bull.* 690-F, 131-43(1918); cf. *C. A.* 12, 1537.—The geographical and geological features of the *Mn* deposits on Wigwam Creek, Cherry Creek and Renova are described. Those on Wigwam Creek appear to be the most extensive and are composed mainly of psilomelane. Manganite is quite common and wad is widely distributed as a brown dust or in soft felt like masses. Analysis of ore selected for shipment gave from 40 to 50% of *Mn*, 1 to 3 of *Fe*, 3 to 4 of *CaO*, and generally less than 2% of *SiO<sub>2</sub>*. Much of the rejected ore apparently contained from 15 to 40% of *Mn*. There is reason to think that additional development will discover additional ore. The deposits near Renova already show several hundred tons of manganiferous *Fe ore* and several thousand tons of *Fe ore*.

L. W. RIGGS.

**Quicksilver deposits of the Phoenix Mts., Arizona.** FRANK C. SCHRADER. U. S. Geol. Survey, *Bull.* 690-D, 95-109(1918).—This deposit, which was discovered in 1916, is located about 10 miles N. E. of Phoenix, and since the discovery of *Hg* several *Cu* prospects have been found in this region. The *Hg* deposits occur in schist belts as cinnabar, metacinnabarite, and as black secondary sulfide of *Hg*. In one prospect a

few globules of native Hg were found. Five mines or prospects are described, three of which have workable ore averaging 3% or more of Hg. L. W. RIGGS.

**Salt Creek oil field, Wyoming.** CARROLL H. WEGEMANN. U. S. Geol. Survey, *Bull.* 670, 49 pp., 7 plates (1918).—The Salt Creek oil field produces daily 10,000 barrels of high-grade paraffin oil. The history of the development and geology of the region are given in detail. Analyses of 2 samples of the oil show 20% distg. below 150°; 31.5 and 47.0, resp., between 150 and 300°; and about 8% of paraffin. Analyses of 9 samples of water in the oil sands show from 3356 to 12554 parts of total solids per million, the lower figures being due to a diln. by surface water. Estimates of future production are given. L. W. RIGGS.

**Petroleum in Japan.** J. MORGAN CLEMENTS. *Econ. Geol.* 13, 512-23 (1918).—Includes a review of the history of the development of the oil fields. There are five districts in Japan proper and one in Formosa. All the oil is found in Tertiary sediments and except in one case they are along the sea coast. There are some flowing wells and one small gusher has been reported. Only one field produces gas in quantity. The oils vary somewhat in different places in the same district and in the different sands of the same field. They are usually heavy, the lighter ones generally being found in the lower horizons. Many statistics of operation and production are included. A. B. PECK.

**The highland border rocks of the Aberfoyle district.** T. J. JERU AND ROBERT CAMPBELL. *Trans. Royal Soc. Edinburgh* 52, I, 175-212 (1918).—A review of previous work and general account of the stratigraphy of the rocks. J. H. B.

**Spotted lakes of epsomite in Washington and British Columbia.** OLAF P. JENKINS. Wash. State Coll. *Am. J. Sci.* 46, 638-44 (1918).—On Kruger Mountain within a few miles of each other are two lakes (one on each side of the international boundary) from which large amts. of natural Epsom salts have been mined and shipped. Photographs of the lakes suggest a snow covered field with dark areas, more or less circular and occupying about half the total area. The dark spots are shallow pools of brine, immediately beneath which are solid rock-like masses of epsomite. The areas between the spots are white and consist of efflorescent salts resting on a foul black mud. During the rainy season the rise of water in the lakes causes the spotted appearance to disappear. The smaller of the lakes is in Washington and contains nearly pure  $MgSO_4$ . The Canadian lake contains  $Na_2SO_4$  along with  $MgSO_4$ . Other lakes in the vicinity show a predominance of  $Na_2SO_4$ . Rocks in the vicinity contain pyrite and pyrrhotite. These may, upon oxidation, have produced sulfates which reacted with Mg and Ca rocks. This view is supported by the fact that between the epsomite and underlying metamorphic rocks is a thin layer of gypsum. Details of mining operations are given; a point of interest is the expansive force with which a satd. soln. of  $MgSO_4$  crystallizes upon a sudden drop in the temp. This was sufficient to split a 3-inch iron pipe from end to end. It was also found that crystallizing salts could not be kept in wooden tanks, as the soln. would work into the cracks and upon crystn. open the joints. Such tanks had to be lined with metal. L. W. RIGGS.

**The "ferrisphere."** A. GUEBHARD. *Compt. rend.* 167, 393-6 (1918).—G. discusses the probable effects of the expansion of Fe at the time of its solidification in the earth's crust upon the constitution of the globe. L. W. RIGGS.

**Bibliography of North American Geology for 1917 with subject index.** JOHN M. NICKLES. U. S. Geol. Survey, *Bull.* 684, 154 pp. (1918); cf. *C. A.* 12, 1447.—The papers listed number 1194, many of which are of chem. interest. These papers give 243 chem. analyses not included in the list of H. S. Washington (*C. A.* 12, 798).

*Metallurgical practice on cinnabar at Idria, Austria*. ROLAND STERNER-RAINER. *Chem. Met. Eng.* 19, 721-7(1918); cf. *C. A.* 9, 191. E. H.

Silver, copper, lead and zinc in the Central States in 1917. J. P. DUNLOP AND B. S. BUTLER. U. S. Geol. Survey, *Mineral Resources of U. S., 1917*, Part I, 73-130 (preprint No. 8, published Oct. 24, 1918). E. H.

Gold, silver, copper and lead in Alaska in 1917. G. C. MARTIN. U. S. Geol. Survey, *Mineral Resources of the U. S., 1917*, Pt. I, 131-45 (preprint No. 9, published Nov. 21, 1918). E. J. C.

A few notes on Bosh tuyères. J. HOLLINGS. *Trans. Iron Steel Inst.*, Sept. 1918 (advance copy), 9 pp.—The practice of using one or more bosh tuyères, temporarily installed, to rid a furnace of an obstinate scaffold dates back many years. Originally designed to meet emergencies only, bosh tuyères which are used continuously have become quite common practice in Germany and France, especially during the last few years. They first saw continuous service in France in 1907. They appear to be used mainly on furnaces making basic iron and more particularly when the slag is high in alumina. If it were possible to obtain ideal conditions in every-day blast-furnace practice, bosh tuyères would probably be neither necessary nor desirable; and if a furnace were correctly designed for a given output and burden, and regularly so driven, they would seldom be required. However, at the present time there is always the temptation to get more out of a furnace than it was designed for. H. describes in detail the installation of bosh tuyères on a 48 ft. furnace at Brymbo. The increased output due to the use of bosh tuyères was approx. 20%. The coke consumption was slightly increased, although this has not exceeded 0.5 cwt. per ton of pig iron. In this particular case 4 bosh tuyères, 4 in. internal diameter, were inserted at a height of 9 ft. 4 in. above the center line of the hearth tuyères. Each bosh is surrounded with a cooler and rigged in the same manner as the ordinary hearth tuyères. The nose of the tuyère was not more than 3 in. beyond the brickwork of the bosh, which consisted of a complete rivetted steel plate sheeting, lined with 13.5 in. brickwork. A table is given showing the no., size, and position of bosh tuyères for a number of different installations. A. L. FIELD.

Further experiments on spontaneous generation of heat in recently hardened steel. C. F. BRUSH, R. A. HADFIELD AND S. A. MAIN. *Proc. Roy. Soc. London (A)* 95, 120-38 (1918); cf. *C. A.* 11, 2878.—The rate of heat evolution and the rate of contraction of quenched steel, after a short initial period has elapsed, is approximately inversely proportional to the time which has elapsed after quenching. This indicates that contraction is closely associated with the heat evolution and that both phenomena are due to the same cause. E. E. RICHARDSON.

Physical tests of rolled shell steel. J. J. MAHON. *Iron Age* 102, 1082-3(1918).—Rolling or forging directly after prolonged heating produces a weakness in steel,

due to the pptn. of ferrite. This weakness may be eliminated by a double rolling operation, consisting of first breaking down the ingots into blooms and reheating before the final rolling. As an intermediate step, it is necessary to cool the billets to a point where no color is visible. Physical tests on steel which has undergone such treatment shows that it accomplishes an increase of 22% in the yield point, of 5.9% in the ultimate tensile strength, a decrease of 5.5% in the elongation percent and an increase of 15% in percentage of yield to elongation percent.

E. E. RICHARDSON.

**Internal strains developed in metals and alloys as a result of rapid cooling.** A. PORREVIN. *Compt. rend.* 167, 531-3(1918).—The internal strain of a metal can be measured by the shape of thin turnings and by accurately measuring the dimensions of the remaining solid. Cylinders, both solid and hollow, of various dimensions and composed of Cu, Ni, brass, ordinary steel or special steel were studied. By rapid cooling from temps. below the critical points, there is developed a longitudinal compression on the external portions and a longitudinal extension at the interior. The extent of the change produced varies with different metals and with pieces of different dimensions. After annealing operations it is desirable in some cases to cool slowly but with certain steels brittleness is produced by slow cooling.

W. T. H.

**The copper-base bearing metals.** G. H. CLAMER. *Chem. Met. Eng.* 19, 656-7 (1918).—A review of the use of Pb in Cu-base bearing metals (cf. *J. Franklin Inst.* 156, 495(1903); *C. A.* 1, 2793; 9, 3211). Alloys have been made carrying as high as 30% Pb with 3% Sn and 2% Sb; also alloys of 65 Cu, 30 Pb, 2 Sn, and 3 Sb; also with the 5% Sn replaced entirely with Sb. Car bearings  $4\frac{1}{4} \times 8$  in. size made from the same pattern and subjected to a breaking stress applied longitudinally at the middle of the back of the bearing and throughout its entire length, broke at the following av. loads: with 2% Sb substitution, 60,000 lbs.; with 3% Sb substitution, 62,000 lbs.; with total substitution, 52,000 lbs.; as compared with a breaking load of 67,000 lbs. for the alloy of Cu 65, Sn 5, Pb 30. The castings produced with each of the 3 above mentioned alloys are not so satisfactory as those made with the straight Sn alloys, being more or less rough, and showing slight globules of Pb on the surface. The hardening effect of Sb is obtained with the sacrifice of ductility. A certain amt. of Ni can be used for replacing Sn with very satisfactory results. The castings produced when Zn is substituted for a certain amt. of Sn are decidedly unsatisfactory. The substitution of Al for Sn is entirely impractical, and such castings are worthless. The substitution of any other metals for Sn in the Cu-Sn-Pb alloys can be made only by sacrificing the quality of the alloy. A bearing metal should possess the following properties: (1) It should be sufficiently rigid to support the load or resist the impact, but yet not so brittle that it will easily crack. (2) It should have as great a yielding or plastic nature as is consistent with its ability to support the load or resist the impact without deformation of the bearing as a whole. (3) The ideal structure combines a hard matrix to support the load and a softer metal or alloy contained within such matrix, to permit the bearing surface to adjust itself to irregularities of surface. (4) It should be easy to handle in the foundry and machine shop. (5) It should be capable of being remelted without deterioration. (6) For use in babbitt-lined bearings, it should be capable of being tinned, so that the babbitt can be applied thereto. (7) It should have good heat cond. in order to dissipate the heat generated by friction.

F. W. SMITHER.

**Solder, its use and abuse.** M. L. LISSBERGER. *Chem. Met. Eng.* 19, 658-9 (1918).—A brief account of the properties of Pb and Sn alloys and the procedure of manufacturing com. solders. L. divides solder into 2 classes (a) that which is used strictly for soldering purposes, or the jointing and holding together of pieces of metal,

and (b) that which is used primarily for filling, in which the joining is a secondary consideration. The greatest abuse of solder is in the use of high-Sn mixts. for these filling metals. A mixt. of 25% Sn and 75% Pb worked at the proper heat and with proper fluxing is high enough for any filling purpose. The best means of conserving solder in can making is to deepen all baths whether on line machinery or for hand dipping. Overheating of the baths should be avoided and the top of all baths covered with a protecting material, *e. g.*,  $\text{NH}_4\text{Cl}$ , oil, charcoal or ash. There is a great waste of Sn in the failure of many plants to save their dross. A mixt. of 46 parts Sn, 54 parts Pb and 0.5 part Sb makes the strongest solder, though for machine work, as low as 38% Sn has given satisfaction. The substitution of Cd for Sn produces a defective solder. Also in *Bull. Am. Inst. Mining Eng.* 1918, 1759-64. F. W. SMITHER.

**Conservation of tin.** Bureau of Standards investigations. G. K. BURGESS AND R. W. WOODWARD. *Chem. Met. Eng.* 19, 660-2 (1918).—The Sn content of nearly all bearing metals can be reduced to some extent, and in some cases actually eliminated without prejudice to the service rendered. A babbitt metal containing 84 Sn, 9 Sb and 7 Cu appears to be as satisfactory in service as one containing 89 Sn, 7.5 Sb, 3.5 Cu, or 91 Sn, 4.5 Sb, and 4.5 Cu. The latter 2 compns. are more fluid in the molten condition than the first named and consequently the lining can be made in a thinner shell with these babbitts and the total amt. of Sn consumed may be less than if the S. A. E. No. 24 were used. If the design of the bearing is not altered to admit of the thinner shell, the lower compn. babbitt should be used in general. The following compns. are also recommended for use where a high grade of lining is required and when a genuine babbitt is often now used: No. 1, Sn 65, Cu 3 to 6, Zn 28 to 30; No. 2, Sn 62, Cu 4, Zn 33, Al, 1; No. 3, Sn 8, Sb 8, Cu 4, Pb 80; No. 4, Sn 5, Sb 7, Cu 2, Zn 76, Pb 10; No. 5, Sn 10, Sb 12.5, Cu 0.5, Pb 77; No. 6, Sn 21.3, Cu 3, Zn 63.3, Pb 12. Nos. 3 and 4 have been found to do the service required of Sn base linings in machine tool bearings; No. 5 can be used on similar bearings where a greater strain is met. No. 6 is in use in Germany as a "best" babbitt to conserve both Sn and Cu. The use of the compn. 87 Pb and 13 Sb for linings on railroad truck journals might be made more universal. Another type of lining metal which deserves serious consideration is one composed almost entirely of Pb with small additions of alkali or alkali earth metal. Certain of these have been given service tests at the Bureau and in many respects were found equal to or superior to genuine babbitt (a table is given showing a summary of these tests and similar tests on a babbitt of compn. 89 Sn, 7.5 Sb, 3.5 Cu). Asked to det. if 4 classes of babbitt metal could be adopted ranging in Sn content as follows: A 89%, B 40 to 50%, C 4 to 6.5%, D 0, it seemed impossible to limit some of the classes to a single compn., because of the fact that several compns. of nearly the same Sn content are in general use for different purposes. Thus in the table below No. A1 is used in aircraft engines, No. A3 is used for automobile engines, No. A4 is found in bearings of elec. machinery. It was thought that class B can be entirely dispensed with, as class C or class D will be found to serve the purpose equally as well. There are some grades of babbitt containing about 65% Sn which do not fall into either class A or B, but which are claimed by the mfrs. to equal the high-Sn babbitt in performance. If these claims can be substantiated this babbitt should be considered as a substitute for alloys in class A. Although high-Sn babbitt of class A is included, the Bureau does not recommend the continuance of its use for many bearings in which it is now used. Although alloy D2 will be found satisfactory in many installations where class A has hitherto been used, its inclusion in class D should not give the impression that it is a low-grade babbitt. The following recommended compns. are for use in the existing situation, where the saving of Sn is of prime importance:

| Class. | No. | % Sn.                                               | % Sb. | % Pb. | % Cu. | % Fe<br>max. | % As<br>max. |
|--------|-----|-----------------------------------------------------|-------|-------|-------|--------------|--------------|
| A..... | A1  | 91                                                  | 4.5   | 1.00a | 4.5   | 0.08         | 0.10         |
|        | A2  | 89                                                  | 7.5   | 1.00a | 3.5   | 0.08         | 0.10         |
|        | A3  | 84                                                  | 9     | 1.00a | 7     | 0.08         | 0.10         |
|        | A4  | 83                                                  | 8.5   | 1.00  | 8.5   | 0.08         | 0.10         |
| C..... | C1  | 5                                                   | 10    | 85    | 0.5a  | ..           | 0.20         |
| D..... | D1  | ..                                                  | 13    | 37    | 0.5a  | ..           | 0.25         |
|        | D2  | Pb about 98%, balance alkali or alkali earth metal. |       |       |       |              |              |

a—maximum.

More than traces of impurities other than those listed above will not be allowed; the following variations above or below the specified amt. will be permissible for the desired elements: for not over 5%, a variation of 0.50; for 5 to 10% inclusive, 0.75; for over 10%, 1.00. The following compns. have been suggested as substitutes for phosphor bronze, although it is the authors' opinion that trouble will sometimes be experienced with Nos. 8, 9, and 10, because of the high Pb content: No. 7, Cu 81, Sn 7, Pb 9, Zn 3; No. 8, Cu 79, Sn 5, Pb 15, phosphor Cu 1; No. 9, Cu 74, Sn 5, Pb 20, phosphor Cu 1; No. 10, Cu 64, Sn 5, Pb 25, Sb 5, phosphor Cu 1; No. 11, Sn 8, Pb 15, Zn 1.5-3, Cu remainder; No. 12, Sn 5, Pb 17.5, Zn 5, Cu remainder. *Structural bronzes:* "Government Bronze" (Navy Specification, 46 M6a, Gun Metal) or 88 Cu, 10 Sn, and 2 Zn can be modified to admit of a saving of Sn without impairment of the physical properties sought. A compn. of 88 Cu, 8 Sn, and 4 Zn is equal to or superior to the ordinary Govt. bronze. Al bronze of compn. 90 Al, 10 Cu, can also be substituted for many uses of Govt. bronze, as can also Mn bronze and naval brass. There have also been introduced several Al bronzes containing small amts. of Fe, which can be either cast or wrought, and which are now being used by several former users of Govt. bronze. Some of the properties of these alloys are given in a table. *Cd as Sn substitute in solder:* The Bureau has been developing such a solder, and lab. tests together with manufg. experience so far point to a compn. of 80 Pb, 10 Sn, and 10 Cd as being practical for many of the purposes for which solder is required. This solder has been tried in the manuf. of tin cans, on roofing materials, and for elec. joints with encouraging results in all cases. Before using it for food containers, it will be necessary to det. its toxic properties under various conditions. A test has also been made of it in the manuf. of automobile radiators with most satisfactory results. The tensile strength of the Cd solder is about the same as that of 40-60 solder, but the ductility is approx. twice that of the ordinary solders. The point of complete liquation is only slightly higher than that of the ordinary compn. of solders, while the range of solidification is considerably greater. A table is given showing some of the provisional data on these solders as compared to the Sn-Pb solders. It is thought that the 80-10-10 solder can be sold at a profit at 35 c. per lb.

F. W. SMITHER.

*The tin-plate industry.* M. D. BUCK. *Chem. Met. Eng.* 19, 659-60(1918).—During the first 5 months of 1918, approx. 11,000,000 lbs. per month of pig Sn were consumed in the U. S. Solder, bearing metals, bronzes, etc., used about 5,500,000 lbs.; collapsible tubes a little more than 250,000 lbs.; Sn-foil about 500,000 lbs.; and the tin- and terne-plate industry somewhat less than 5,000,000 lbs. In an effort to reduce this consumption and thus conserve our Sn supplies, the following methods are suggested: (1) Salvage. (2) Substitution of other metals for Sn. (3) Curtailment, for the time being, of certain lines of manuf., not absolutely essential to the prosecution of the war. These methods and their application are briefly discussed, especially their bearing on the canning industry.

**Ore concentration.** R. B. MARTIN. Can. 187,263, Oct. 29, 1918. Oxide ores are sepd. as oxides by employing in the pulp soln. a sol. sulfide in such a small proportion as will not convert even the surfaces of the oxide ore particles into sulfide in a flotation process with agitation and aeration.

**Concentrating ores.** W. A. SCOTT. Brit. 119,224, Aug. 14, 1918. A method of carrying out a flotation process consists in introducing into an ore pulp a "bubble-modifying" permanent gas, usually in admixt. with air or like inert gas, whereby the concentrates are caused to rise to the surface of the liquid. The "bubble-modifying" gas is preferably a hydrocarbon such as  $C_2H_2$  or  $CH_4$ , or a distn. gas such as lighting gas, and the gas or mixt. of gases may be introduced by mechanical agitation or through a porous medium.

**Concentrating ores.** W. W. WEBSTER. Brit. 119,050, June 14, 1917. In the concn. of Sn and W ores, the finely divided ore, which may be first classified, is subjected to the action of Na or K hydroxide, silicate, carbonate, or phosphate,  $NH_3$ , borax, or silicic acid sol, preferably by being agitated in  $H_2O$  with a small proportion of one or more of the reagents, and then submitted to mechanical sepn., such as on tables or vanners, by panning, or in upward-current classifiers. Lime and soda ash may be used in place of NaOH. In some cases, the reagent may be added to the  $H_2O$  with which the ore is mixed for sepn.

**Treating ores.** G. RIGG. Brit. 119,223, July 15, 1918. ZnS ores are desulfurized by roasting in two stages, the S content being reduced in the first stage to such an extent that fusion and slagging are avoided in the second stage, which is effected by blast roasting, e. g., in the Dwight-Lloyd app. The first stage may be carried out by partial roasting to the required extent, or by partial or complete roasting and mixing the product with unroasted ore. The partially roasted ore may be mixed with a binder such as clay or slime concentrates and  $H_2O$  before treatment by the blast roast. In the blast roast steam or  $H_2O$  vapor may be mixed with the air passed through the ore. In some cases, part or all of the gases from the blast roaster may be passed over one or more hearths of the preliminary roasting furnace so as to increase their content of  $SO_2$ .

**Treating ores.** A. L. PELLERGRIN. Can. 187,620, Nov. 26, 1918.  $PbVO_4$  is sepd. from  $PbMoO_4$  by sulfidizing the latter and submitting the mixt. to flotation. The vanadate and molybdate may be removed from the other Pb minerals by sul-

flotizing the latter and submitting to flotation, then the  $\text{PbVO}_3$  and  $\text{PbMoO}_4$  may be sepd. as above.

**Apparatus for concentrating ores by flotation.** F. GROCH. U. S. 1,281,351, Oct. 15.

**Ore-concentrating (flotation) apparatus.** F. GROCH. U. S. 1,283,159, Oct. 29.

**Gold concentrator.** A. R. MACKIE. Can. 185,636, July 23, 1918.

**Metallurgical furnace.** J. KRALUND. U. S. 1,284,711, Nov. 12. The furnace is especially adapted for prepg. alloys of high m. p. for pressure die casting.

**Zinc retort furnace.** A. JONES. U. S., 1,282,847, Oct. 29.

**Apparatus for filtering solutions from ore residues.** E. E. HOWSON. U. S. 1,284,347, Nov. 12.

**Apparatus for filtering solutions from ore slimes.** O. J. SALISBURY. U. S. 1,283,925, Nov. 5.

**Apparatus and method of operating for treating ore slimes with cyanide or other solutions.** L. C. TRENT and S. W. MUDD. U. S. 1,283,363-4-5, Oct. 29.

**Apparatus for precipitating constituents from solutions obtained from ores.** D. C. WALKER. U. S. 1,281,443, Oct. 15. A cyanide soln. of Au may be continuously passed over Zn shavings in the app.

**Extracting metals from ores.** F. L. ANTISELL. U. S. 1,282,521, Oct. 22. In leaching Cu or other metals from ores, the ore is leached with a soln. satd. with respect to impurities in the ore but capable of dissolving the Cu or other desired metal (e. g., in the case of Cu a soln. containing  $\text{H}_2\text{SO}_4$ ) and a portion of the soln. formed by such leaching is continuously withdrawn to an electrolytic system where the Cu is in part deposited, and the soln. which is depolarized during the electrolysis is returned to the leaching system.

**Recovering metals from ores.** C. L. LARSON. U. S. 1,284,910, Nov. 12. Ore, tailings or other mill or smelting products which contain Pb and may also contain Cu, Ag or Au are leached with strong brine to dissolve the metal values; metals other than Pb are pptd. from the soln. and the Pb is then removed electrolytically. After eliminating accumulated sulfates from the barren brine it may be reused for leaching.

**Extracting platinum from sands.** R. THAYER. U. S. 1,281,878, Oct. 15. Pt or similar metal is recovered from granular siliceous ore by diffusing a 0.5% NaOH soln. through a charge of the ore, heating the wetted mass in a closed receptacle to volatilize the metal and thus effecting its sepn. by distn. U. S. 1,281,879 relates to the recovery of metals from like materials by passing a current of heated Cl gas through the charge, leading the gas current from the charge into a body of  $\text{H}_2\text{O}$  or other liquid to dissolve the compds. formed and volatilized with the gas current and leaching out residual metal compds. from the charge.

**Molybdenum.** J. A. HOLLADAY. U. S. 1,281,961, Oct. 15. A wulfenite concentrate or similar material is smelted to eliminate Pb and produce a sol. molybdate slag, the latter is leached with  $\text{H}_2\text{O}$  or a dil. soln. of  $\text{CaCl}_2$  and Ca molybdate is afterward pptd. from the soln. thus obtained, by adding an excess of  $\text{CaCl}_2$ . The ppt. on smelting gives a Mo which is 97% pure.

**Tungsten.** O. BERTOYA. Brit. 119,117, Oct. 15, 1917.  $\text{WO}_3$  is reduced to metal by the action of H or gas containing over 50% H while passing through a series of externally heated inclined retorts down which the material slides.

**Leaching copper ores.** A. W. HAHN. U. S. 1,282,415, Oct. 22. Several tanks are arranged in series circuit, each containing ore, and an acid leaching soln. is ad-

vanced progressively through the series. The soln. is neutralized in the last tank of the series by contact with the ore in this tank which renders the ferric-Fe content of the soln. permanently insol. in the acid-leaching liquor and the soln., after sepn. of the pptd. Fe compds., is led to an electrolytic cell and, after electrolysis to reduce ferric to ferrous salts, is led back for further use in extn.

**Furnace for producing steel directly from iron ore.** L. T. GROUSELLE. U. S. 1,284,094, Nov. 5. The furnace comprizes reducing and melting chambers which are arranged for the sep. introduction of heating gases into each of the chambers and for the sep. exit of waste gases.

**Steel for poppet-valves.** C. A. PFANSTIEHL. U. S. 1,283,287, Oct. 29. Heads of valves for internal-combustion engines are formed of W-steel and the stems are formed of a steel containing 2-3% Ni which has a coeff. of expansion sufficiently less than that of cast Fe to compensate for the difference in operating temp. between the valve stem and the supporting parts of the engine.

**Apparatus for the melting of iron, steel and other substances not easily reduced to the molten condition.** F. G. C. RINCKER. Can. 187,627, Nov. 26, 1918. A furnace has in combination a chamber for converting liquid hydrocarbons into gas immediately on its entry thereinto, a superheater for the gas, an air heater and a combustion heater with valves for control and means for cleaning.

**Finishing gears or other carbonized steel articles.** J. F. SALLOWS. U. S. 1,282,467, Oct. 22. After gears or other steel or carbonized Fe articles are rough-formed and rough-machined they are deeply carbonized by case-hardening, quenched in oil, annealed in C dust, heated and then allowed to cool in the atm. while still enclosed in the C dust, then machined to produce the desired finish, reboxed in insulating material such as C dust, reheated, and quenched in oil or H<sub>2</sub>O according to the grade of steel which it is desired to produce.

**Smelting ores with carbon.** J. H. GRAY. U. S. 1,283,500, Nov. 5. In smelting ores of Fe or other metals by reduction with C, a blast of pure O is introduced into the charge of ore and C so that the combustion of C under the influence of the blast is practically completed in the immediate neighborhood of the points of admission of the blast and an intense heat is thus generated in a comparatively small space and complete reduction of the ore is accomplished in substantially the same space. Only sufficient charge is maintained above this space to keep it filled.

**Roasting ores containing antimony sulfides.** W. A. INGHAM. U. S. 1,283,782, Nov. 5. A thin layer of ground ore containing Sb sulfides, which also may contain Au, Ag and As is heated in a closed roasting chamber to a temp. sufficient to volatilize the Sb sulfides. The vapors of the latter are led off from the roasting chamber and are oxidized to form Sb oxide.

**Reducing metallic compounds.** H. FOERSTERLING. U. S. 1,283,716, Nov. 5. In the simultaneous production of NaCN and reduction of metal compds., Na vapors are caused to react with the oxide of the metal to be reduced, in the presence of coke and N or similar carbonaceous and nitrogenous materials. The heat generated by the formation of the cyanide renders the reaction practically self-sustaining as regards heat-supply.

**Separating ore values from gang.** W. O. ARZINGER. U. S. 1,282,730, Oct. 29. Values are floated from ores such as those containing graphite by the action of a body of H<sub>2</sub>O and oil or other sepg. liquid into which air or other gas is entrained by the action of jets of liquid impinging upon its surface.

**Treating gold and silver ores with cyanide solutions.** A. A. LOCKWOOD. U. S. 1,283,236, Oct. 29. Pulped ore is agitated in a body of cyaniding soln., and a con-

tinuous current of pulp is led from the agitating vessel to one end of a sep. electrolytic pptg. vessel which contains a series of longitudinally arranged depending electrodes. An elec. current is supplied to the pulp of sufficient density to ppt. the precious metals and the pulp is maintained in suspension in the pptg. vessel by a jet of air and is finally removed from the other end of the vessel, led back to the cyaniding tank and the operation is repeated without filtration or sedimentation. The pat. describes an app. for carrying out the method.

**Reducing tungsten trioxide.** C. A. PFANSTIEHL. U. S. 1,283,286, Oct. 29. A blast of highly heated H is passed over the surface of the  $WO_3$  to be reduced which is at the same time heated just sufficiently to compensate for heat lost by radiation and to supply heat necessary to vaporize the  $H_2O$  produced by the reduction reaction.

**Coating carbon conductors with copper.** S. TROOD. U. S. 1,281,716, Oct. 15. Finely divided C which is intended for use in making dynamo-elec. machine brushes or similar articles are coated with a film of Cu amalgam and the Hg is subsequently removed by applying heat and pressure to the material.

**Plating articles with gold.** F. O. ANDRES. U. S. 1,281,262, Oct. 15. Articles of metal or glass or similar material are treated with a soln. formed of  $AuCl_3$ ,  $K_2CO_3$ , sugar and  $H_2O$  so as to form a film of the soln. on the article and a soln. containing  $AgNO_3$  and Cu nitrate may be then applied to the film to form a toning backing for the Au coating. Heating is not required to form the Au film.

**Starring mixture for antimony smelting.** C. YU WANG. U. S. 1,284,164, Nov. 5. A starring mixt. for use in Sb smelting is formed of Fe sulfide resulting as a by-product in the pptn. process of Sb smelting, mixed with about 80% its wt. of  $K_2CO_3$ .

**"Core-oil" for use with sand in metal-founding.** S. G. LOWE. U. S. 1,283,237, Oct. 29. A mixt. formed of linseed oil 24, rosin 33.6, light petroleum "distillate" 29.8 and kerosene 12.5 parts is used for binding sand to form cores.

**Detinning with chlorine.** W. ZACHARIAS. U. S. 1,283,016, Oct. 29. In detinning tin-scrap with Cl, the temp. within the reacting mass is regulated by adding finely divided Sn in sufficient amt. to maintain the temp. below that at which the Fe will be attacked.

**Case hardening.** A. E. BAMFIELD. Brit. 118,983, Feb. 18, 1918. A mixt. consisting of 50 parts of  $Na_2SiO_3$ , 25 parts of China clay, 18.75 parts of amorphous  $SiO_2$ , and 7.85 parts of silver sand is applied as a protective coating to parts of articles not to be carburized during the case hardening process, and is used also to prevent oxidation of the carburized articles during subsequent annealing.

**Casting rare-earth metals.** ALPHA PRODUCTS CO. Brit. 119,244, Sept. 17, 1918. Ce and similar rare-earth metals and their alloys for tinder lighters, etc., are melted under a protective coating of fused Ba or Na chloride or other salt inert to the metal or in an atm. of H and cast, at a temp. only slightly above the m. p., in a heated mold or one with thin walls and cooled at the ordinary room temp. The  $BaCl_2$  is first melted then an alloy of Ce, La, and Di and possibly small quantities of Er and Th, but with less than 10% of Fe, broken into lumps about 1 in. in diam., is added. When the crucible is half full of molten metal, loose coils of Fe wire 40 or 50 g. in wt. are added until the alloy contains 30% of Fe. The temp. is raised to  $1000^\circ$ , the mass stirred gently and then poured into an Fe mold in halves clamped by angle bars and bolts and having grooves and runner connecting them. It may have its surface dusted or coated with  $MgO$ , rolling scale, or Sn plating. If the crude metal is very impure or non-homogeneous it may first be fused under purifying salt such as  $BaCl_2$  and then cast into bars to be broken up, or the salt may be removed and fresh dehydrated salt added. Cu or Mg may be added to the alloy to increase the heat of the spark.

**Mold for casting metals.** M. SMITH. U. S. 1,281,679, Oct. 15. Molds for casting light metal articles with fine details are formed of a mixt. of plaster of Paris 40, asbestos fibers 30 and brick dust 30 parts.

**Welding composition.** C. C. ROBERTS. U. S. 1,283,909, Nov. 5. A mixt. for use in welding Fe, steel or other metals is formed of finely divided Fe 20, sand 50, glass 5, cryolite 10 and calcined borax 15 parts.

**Welding and brazing.** E. H. JONES. Brit. 119,096, Sept. 21, 1917. Metals are united by fusion under the heat of an oxyacetylene or other blowpipe, or cutting tools and dies are coated with metals or alloys such as high-speed steel, by employing metal rods, tubes, etc., which are electroplated with other metals, or are made so as to enclose other metals or alloys, or may have both these features in combination. In the case of Fe or steel, the surface of the rod or tube may be case-hardened to provide an additional amt. of C.

**Desiccating air for use in blast-furnaces.** L. GOLDMERSTEIN (name now judicially changed to L. Cammen). U. S. 1,282,686, Oct. 22. The air is passed through a flowing soln. of  $\text{CaCl}_2$ , maintained nearly satd., at a temp. of about  $-9^\circ$ , in a circulating system, in one portion of which absorbed moisture is removed from the soln. before its return for further use.

**Zinc alloy.** F. S. HODSON. Brit. 119,486, July 16, 1917. An alloy contains Zn 80-85, Al 14-19, Cu 1-2%. An alloy of the Cu and Al is preferably made first,  $\text{H}_2\text{O}$ -quenched, and remelted with the Zn. The final alloy is  $\text{H}_2\text{O}$ -quenched. According to the provisional specification, the alloy may contain also Mg. Cf. C. A. 12, 2080.

**Refining alloys of lead, tin, copper or antimony.** F. A. STIEF. U. S. 1,283,427, Oct. 29. Alloys of Pb, Sn, Cu or Sb, containing As, are heated to redness in contact with Fe and C and the speiss is sepd. from the molten metal by gravity.

**Gold alloy.** G. H. DUFOUR. U. S. 1,282,055, Oct. 22. An alloy for making jewelry is formed of Au 74, Pt 4.5 and Pd 21.5%. It is similar to Pt in appearance and other physical properties.

**Alloy of gold, silver and palladium.** W. E. MOWREY. U. S. 1,283,264, Oct. 29. An alloy of Pd 15, Ag 35 and Au 50 parts is made, for use in dental, electrical and jewelry work, as a substitute for Pt.

**Ferrosilicon.** J. E. JOHNSON, JR. U. S. reissue 14,547, Nov. 12. See original pat. 1,231,260; C. A. 11, 2322.

---

## 10. ORGANIC CHEMISTRY.

---

CHAS. A. ROUILLER.

**Rudolph Nietzki 1847-1917.** E. NOELTING. *Helvetica Chim. Acta* 1, 343-430 (1918).—Biographical with a review of Nietzki's work on aniline black, the quinones, azo compds., safranines, oxazines, thiazines, azines, fluoridines, ethers of fluorescein and of phenolphthalein, isopurpuric acid, tetraminobenzenes, nitraminosulfonic acids and naphthalene derivs. E. H.

**Organic chemistry in relation to industry.** M. D. FORSTER. *Color Trade J.* 3, 400-5 (1918); cf. C. A. 12, 1885. E. H.

**Synthesis of acetic acid and alcohol by means of acetylene.** GUY CHAZEL. *Rev. produits chim.* 21, 194-5, 210-1 (1918).—To form  $\text{AcOH}$  or  $\text{EtOH}$  from  $\text{C}_2\text{H}_2$  it is necessary to pass through  $\text{AcH}$ , which is now made by the method of Grüstain which consists of passing  $\text{C}_2\text{H}_2$  into a 15-30% soln. of  $\text{H}_2\text{SO}_4$  containing a Hg salt in soln. and

mechanically agitated. Details are given for carrying out this method. The yield is good but some difficulties are encountered: necessity for costly agitation, obstructing action of the air upon the absorption of the  $C_2H_2$ , polymerization of the aldehyde, and necessity for regenerating the Hg. Most of these difficulties are avoided by using the process of H. Dreyfus in which a strong AcOH is substituted for dil.  $H_2SO_4$ . No agitation is needed in this method, and furthermore the subsequent oxidation of the AcH to AcOH can be effected in the one operation. If it is desired to carry on the oxidation in a separate chamber, this is best done by the method of Behrens, who passes  $O_2$  into the aldehyde containing 1% of CeO as a catalyst. This method involves some danger of explosion, which is avoided by substituting 0.5%  $Mn(OAc)_2$  for the CeO. To convert the MeCHO into EtOH the method of Sabatier is used; in this the aldehyde and  $H_2$  are passed through a tube containing reduced Ni and heated to  $140^\circ$ . The various methods are described in detail.

R. N. HARGER.

**Electrolytic oxidation of benzene.** CHAVEAU CLAUDIUS. *Rev. produits chim.* 21, 219(1918).—Upon trying out the oxidation of PhH and subsequent reduction of the quinone to quinol, according to the method of Kempf (Frld. 1900) the author was successful with only the second step. He found that by adding a little  $PbO_2$  to the anode mixt. the oxidation was much accelerated. Detailed instructions are given for the modified process.

R. N. HARGER.

**The manufacture of methylene blue.** BILE. *Rev. produits chim.* 21, 195(1918).—Details are given for carrying out the manuf. of methylene blue according to the method of Bernthsen. The article includes equations explaining the reaction.

R. N. H.

**The pungent principles of ginger.** II. HIROSHI NOMURA. *Sci. Rep. Tohoku Imp. Univ.* 7, 67-77(1918); cf. C. A. 11, 2662.—After zingerone was removed by the method employed in the previous work, the  $Et_2O$  soln. was washed with  $Na_2CO_3$  and then with  $H_2O$  and evapd. The residual oil was fractionated under 21 mm. and the more pungent fraction again fractionated under 0.5-0.6 mm. and the process again repeated under 0.4-0.5 mm., the material from the last fractionation coming over at  $165-202^\circ$ , the major portion at  $175-85^\circ$ . A portion of the  $175-85^\circ$  fraction was analyzed and the remainder fractionated into 3 parts:  $174-9^\circ$ ,  $179-86^\circ$  and  $186-9^\circ$  and each of these fractions analyzed. The results from the four analyses were practically identical, which showed that there was difficulty in keeping a constant vacuum, or else that the material consisted of a mixt. of isomers. The mol. wt. in freezing PhH was 262. From these results N. ascribes to the oil the formula  $C_{17}H_{34}O_2$  and gives it the name *shogaol* from "shoga," the Japanese word for ginger. Shogaol is an oil of pale straw color,  $d_{25} 1.0448$ ,  $[\alpha]_D^{25} 1.52407$ , sol. in  $EtOH$ ,  $(C_6H_{11})_2O$ , and  $AcOH$ , gives a green color with  $FeCl_3$ , and reduces  $NH_3-AgNO_3$ . Zeisel's method (*Monatsh.* 6, 989) indicated that the compd. contains one MeO group, and when refluxed with  $AcOH$  and fused  $AcONa$  it yielded an *acetyl derivative* (B)  $C_{19}H_{38}O_4$ , a yellow oil  $b_{p.} 183-8^\circ$ . Both shogaol and (B) rapidly absorbed Br in  $CHCl_3$ , and when excess of Br was added substitution took place as shown by the evolution of HBr. When  $H_2$  was passed into an  $Et_2O$  soln. of shogaol in which Pt black was suspended addition took place giving  $C_{17}H_{36}O_2$ , a pale yellow oil,  $b_{p.} 166-9^\circ$ , which would indicate one double bond. *Methyl shogaol* (C),  $C_{18}H_{36}O_2$ , yellow oil,  $b_{p.} 160-5^\circ$ , was obtained by shaking an alk. soln. of shogaol with  $Me_2SO_4$ . When (C) was heated with alc.  $NH_4OH.HCl$  it yielded an oil containing N which could not be crystd. and since neither shogaol nor (C) would form a bisulfite compd. N. concluded that the third O in shogaol is ketonic. *Ethyl shogaol*, (D)  $C_{19}H_{38}O_3$ , a pale yellow oil,  $b_{p.} 181-6^\circ$ , was formed by refluxing an alc. soln. of shogaol with  $EtI + KOH$ . When (D) was oxidized with alk.  $KMnO_4$  it yielded ethylvanillic acid. From

these results N. ascribes to shogaol the formula  $1,2,4\text{-C}_6\text{H}_3(\text{OH})(\text{OMe})(\text{C}_6\text{H}_7\text{CO})$ . In its b. p. shogaol resembles a compd. described by Garnet and Grier (*Pharms. J.* [iv] 25, 118) and a similar one obtained by Nelson (*C. A.* 11, 2333) on distg. gingerol, but its compn. differs from Nelson's compd. R. N. HARGER.

**Synthesis of some phenolic ketones and their tastes.** HIROSHI NOMURA AND FUSATOSCHI NOZAWA. *Sci. Rep. Tôhoku Imp. Univ.* 7, 79-92 (1918).—To det. their pungency and study the conditions influencing the same, various phenolic ketones resembling zingerone (*C. A.* 11, 2662) were synthesized and tasted. The same method of prepn. was used for all: the substituted benzaldehyde was condensed with acetone (acetophenone in the case of (M)) in the presence of caustic soda (Claisen reaction) and the resulting unsatd. compd. reduced with  $\text{H}_2$  in the presence of Pt black. All yields were good except in the case of (H). Piperonal and acetone were condensed giving 3,4-methylenedioxyethyl methyl ketone (A), which was found to m.  $108-9^\circ$  instead of  $96.5^\circ$  as found by Rousset (*Bull. soc. chim.* [3] 13, 348) or  $107^\circ$  as reported by Haber (*Ber.* 24, 618). (A) upon reduction gave 3,4-methylenedioxyphenylethyl methyl ketone, (B),  $\text{CH}_3\text{O}_2\text{C}_6\text{H}_3\text{CH}_2\text{CH}_2\text{Ac}$ , a colorless oil, b.  $175.5^\circ$ , which upon long standing solidified and m.  $50-1^\circ$  (cf. *C. A.* 10, 2719). By reducing  $p\text{-MeCOCH:CHC}_6\text{H}_4\text{OMe}$  the authors obtained  $p\text{-MeCOCH}_2\text{CH}_2\text{C}_6\text{H}_4\text{OMe}$  (C). When (C) was boiled with glacial AcOH and concd. HBr the Me group was split off yielding  $p\text{-hydroxyphenylethyl methyl ketone}$ ,  $\text{HOC}_6\text{H}_4\text{CH}_2\text{CH}_2\text{COMe}$  (D), colorless needles, m.  $82-3^\circ$ , sol. in  $\text{Et}_2\text{O}$ , EtOH and in cold ligroin, and giving a green soln. with  $\text{FeCl}_3$ . (D) was also prepd. by reducing  $p\text{-HOC}_6\text{H}_4\text{CH:CHCOMe}$ . By reducing  $\text{PhCH:CHCOMe}$  (E) the authors obtained  $\text{PhCH}_2\text{CH}_2\text{COMe}$  (F), b.  $231.5-3.0^\circ$  and not  $235-6^\circ$  as found by Harries and Eschenbach (*Ber.* 29, 383). The *o*-compd. (G) corresponding to (D) was prepd. in a similar manner. *m*-Hydroxystyryl methyl ketone (H),  $\text{HOC}_6\text{H}_4\text{CH:CH:COMe}$ , colorless needles, m.  $97-8^\circ$ , upon reduction gave *m*-hydroxyphenylethyl methyl ketone,  $\text{HOC}_6\text{H}_4\text{CH}_2\text{CH}_2\text{COMe}$ , colorless crystals, m.  $85-6^\circ$ . The condensation of *o*-vanillin and acetone yielded 2-hydroxy-3-methoxystyryl methyl ketone (I),  $2,3\text{-HO(MeO)C}_6\text{H}_3\text{CH:CHCOMe}$ , yellow crystals from dil. EtOH m.  $77-77.5^\circ$ . When (I) was heated above its m. p. it lost 8.32% in wt. and yielded the corresponding monohydrate (J), yellow crystals, m.  $81-2^\circ$ . That (J) is a hydrate was shown by the fact that it gave 2.78 active H atoms by Zerewitinoff's method (*Ber.* 40, 2028), is readily reduced by  $\text{H}_2$  in the presence of Pt black, and when recrystd. from PhH it yielded (I). Upon reduction both (I) and (J) gave 2-hydroxy-3-methoxyphenylethyl methyl ketone (K),  $2,3\text{-HO(MeO)C}_6\text{H}_3\text{CH}_2\text{CH}_2\text{COMe}$ , a clear oil, b.  $206-7^\circ$ , which turned brown upon standing. Acetophenone was condensed with vanillin and a mixt. of two products resulted which were sepd. by treatment with 2% NaOH, the insol. portion being vanillalacetophenone,  $4,3\text{-HO(MeO)C}_6\text{H}_3\text{CH}(\text{CH}_2\text{Bz})_2$ , colorless crystals, m.  $121-2^\circ$ , mol. wt. 370-83 in boiling PhH, not reduced by  $\text{H}_2$  in the presence of Pt black, benzoyl derivative, m.  $133^\circ$ ; while the portion sol. in 2% NaOH was vanillalacetophenone,  $\text{PhCOCH:CHC}_6\text{H}_3(\text{OMe})\text{OH}$ , yellow crystals, m.  $92-3^\circ$ . (L) upon reduction gave 4-hydroxy-3-methoxyphenylethyl phenyl ketone,  $\text{PhCOCH}_2\text{CH}_2\text{C}_6\text{H}_3(\text{OMe})\text{OH}$ , (M), colorless scales, m.  $97.5-8.0^\circ$ . With the exception of (E), the reduction of all the unsatd. compds. increased the soly. in org. solvents, and also the pungency, which in the case of the unsatd. compds. was developed on the tongue only after some time. (E), however, was rather sol. in org. solvents and had a pungent taste. (F), (B) and (D) were all pungent, which would indicate that a free phenolic OH group is unnecessary to pungency, although the position of the free OH-group has an important influence upon the taste, since the taste of (G) resembled that of (K), while (D) and (M) had similar tastes. The pungency of (G) and (D) was less than that of (K) or (M), indicating that a MeO group in the *m*-position increases the pungency. The taste of (M) was

very similar to that of zingerone and, since they differ only in the side chain, N. and N. conclude that the influence of the side chain is less than that of the various substitutions in the PhH ring.

R. N. HARGER.

**The Beckmann rearrangement.** VIII. MITSURU KUHARA, MAOMICHI AGATSUMA AND KIUKICHI ARAKI. *Mem. Coll. Sci. Kyoto Imp. Univ.* 3, No. 1, 1-16(1917); cf. *C. A.* 11, 579-80.—When  $\text{Ph}_2\text{C:NOAc}$  and dehydrated  $\text{PhSO}_3\text{H}$  were heated to fusion a violent reaction took place evolving  $\text{AcOH}$  and the residue was probably  $\text{PhC(OSO}_2\text{Ph):NPh}$  as shown by the fact that it yielded  $\text{PhCONHPh}$  upon the addition of water. This would seem to indicate that the substitution of the  $\text{Ac}$  group by a group of greater acidity permits the reaction to take place and the authors believe that the occurrence of a reaction of this type explains why the addition of  $\text{HCl}$  to  $\text{Ph}_2\text{C:NOAc}$  causes rearrangement to take place, an additive compd. being first formed:

*Diphenyl ketoxime hydrochloride*,  $\text{Ph}_2\text{C:NOH.HCl}$  (A), produced by passing dry  $\text{HCl}$  into  $\text{Ph}_2\text{C:NOH}$ , white crystals, fused at  $128^\circ$  and upon further heating at the same temp. colored yellow with the evolution of  $\text{HCl}$ , and then became suddenly cryst. under violent reaction. The product was  $\text{PhCONHPh}$ . The reaction was also produced at  $125^\circ$  by passing  $\text{HCl}$  into the melted oxime, a 95% yield of  $\text{PhCONHPh}$  being obtained, while the same rearrangement of the hydrochloride was produced by dehydrating agents,  $\text{ZnCl}_2$  causing the reaction to begin at  $70^\circ$  and to run almost to completion at  $90^\circ$ , while  $\text{CCl}_4\text{CHO}$  caused a 91% rearrangement when heated with the hydrochloride at  $90^\circ$  for 10 minutes and practically complete rearrangement when the mixt. was kept at  $25^\circ$  for 2 days. The hydrochloride of  $\text{Ph}_2\text{C:NOAc}$  when heated above its m. p. did not rearrange but split off  $\text{MeCl}$ . When  $\text{Ph}_2\text{C:NCl}$  (C) was fused with  $\text{KOH}$  a violent reaction took place, evolving considerable  $\text{MeCOPh}$  and some  $\text{PhNH}_2$ , while  $\text{Ph}_2\text{C:NH.HCl}$ ,  $\text{Ph}_2\text{C:NOH}$  and  $\text{Ph}_2\text{C:NOAc}$  under similar treatment gave no  $\text{PhNH}_2$ . Since heat or dehydrating agents caused rearrangement in the case of (A), the authors write the equation similar to (1),  $\text{H}_2\text{O}$  instead of  $\text{AcOH}$  being split off. The fact that (C) has previously resisted all attempts to cause it to rearrange and only rearranges when fused with  $\text{KOH}$ , is explained by assuming that its  $\text{Cl}$ , which is derived from  $\text{PCl}_5$ , is positive and changes to negative "under the influence of the alkali." The *dibenzyl ketoxime, benzenesulfonate*  $(\text{PhCH}_2)_2\text{C:NOSO}_2\text{Ph}$ , colorless crystals, m.  $64^\circ$ , sol. in  $\text{EtOH}$ ,  $\text{PhH}$  and  $\text{CHCl}_3$ , was prepd. from  $(\text{PhCH}_2)_2\text{C:NOH}$  and  $\text{PhSO}_3\text{Cl}$ . When heated to  $74^\circ$  it reacted with explosive violence, giving a yellow viscid product, which upon being added to  $\text{H}_2\text{O}$  yielded  $\text{PhSO}_3\text{H}$  and *benzylphenylacetamide*,  $\text{PhCH}_2\text{CONHCH}_2\text{Ph}$ , colorless scales, m.  $118-9^\circ$ . *Diphenyl ketoxime m-nitrobenzenesulfonate*,  $\text{Ph}_2\text{C:NOSO}_2\text{C}_6\text{H}_4\text{NO}_2$ , m.  $24^\circ$ , upon being melted suffered spontaneous rearrangement yielding a yellow liquid, which when treated with  $\text{H}_2\text{O}$  gave  $\text{PhCONHPh}$  and  $m\text{-NO}_2\text{C}_6\text{H}_4\text{SO}_3\text{OH}$ . Two other esters of  $(\text{PhCH}_2)_2\text{C:NOH}$ , the *acetyl ester*, m.  $33-4^\circ$ , and the *benzoyl ester*, m.  $60.5^\circ$ , were prepd. but did not show rearrangement upon being heated. When  $\text{Me}_2\text{C:NOSO}_2\text{Ph}$  was heated to  $130^\circ$  a reaction occurred and the product, treated with alkali, liberated  $\text{MeNH}_2$ , but the authors were unable to isolate  $\text{AcNHMe}$ .  $\text{Me}_2\text{C:NOCOCH}_2\text{Cl}$  suffered rearrangement when heated to  $195^\circ$  and from the product  $\text{AcNHMe}$  was isolated. Since results in this and previous work show that the rearrangement of the same acyl ester of different ketoximes takes place at different temps., the hydrocarbon radical must exert an influence upon the rearrangement (both the hydrocarbon exchanging places and the one opposite); and since the different acyl esters of the same ketoxime rearrange at widely different temps., the acyl group too must exert a strong influence, and as a con-

sequence "the most conceivable assumption is that the exchange of radicals would be simultaneous."

R. N. HARGER.

**Constitution of carbamides. VII. Mechanism of the synthesis of urea from the interaction of carbonyl chloride and ammonia.** EMIL ALPHONSE WERNER. Trinity Coll., Dublin. *J. Chem. Soc.* 113, 694-9(1918).—This reaction is not a simple one, such as the interaction of  $\text{AcCl}$  and  $\text{NH}_3$ , and it is now shown that the so-called secondary products indicate the true origin of urea (*A*) as formed from  $\text{COCl}_2$  and  $\text{NH}_3$ . In each of 3 expts. 12 g.  $\text{COCl}_2$  in 400 cc. freshly distd. PhH were placed in a stout, wide-mouthed bottle provided with a cork carrying a delivery tube, thermometer, and exit tube. A slow current of dry  $\text{NH}_3$  was delivered on to the surface of the continually shaken liquid, but as the product was gelatinous, uniformity in the progress of the reaction and const. temp. were not maintained. In expt. I the bottle was immersed in  $\text{H}_2\text{O}$  at  $0^\circ$ , in II in  $\text{H}_2\text{O}$  at  $15^\circ$ , and in III no cooling was used. In I, II, III, resp., the max. temps. reached were  $20-5^\circ$ ,  $40-50^\circ$ ,  $65-70^\circ$ ; (*A*) formed, 31.7, 37.3, 41.2% of the theory; biuret (*B*), 14.4, 10.1, 7.8%; ammeline (*C*) 7.65, 8.6, 10.6%; cyanuric acid (*D*), 3.45, 6.4, 5.98%; cyamelide (*E*), 0.69, trace, none. (*D*) and (*E*) owe their formation to the polymerization of  $\text{HOCN}$ , and since there exists no tendency towards the formation of a compd. containing the system  $:\text{C}(\text{NH}_2)_2$ , (*C. A.* 12, 2193) the true course of the reaction is:

Since  $\text{HOCN}$  is generated in the presence of  $\text{NH}_3$ , the origin of the (*A*) is self-evident, the reaction really being no more than Wöhler's synthesis in another form. It had previously been shown that while (*B*) is formed from  $\text{HOCN}$  and (*A*), (*C*) is formed from  $\text{HOCN}$  and (*B*) (*C. A.* 7, 3315; 8, 1415), and (*B*) was therefore overlooked by previous investigators of the reaction between  $\text{COCl}_2$  and  $\text{NH}_3$  (Regnault, *Ann. chim. phys.* [2] 69, 180(1838); Natanson, *Ann.* 98, 287(1856); Bouchardat, *Compt. rend.* 69, 961(1869); Fenton, *J. Chem. Soc.* 35, 793(1879); Hantzsch and Stuer, *Ber.* 38, 1041, 2326(1905)). The theoretical yields in the above table were calcd. as follows: 1  $\text{COCl}_2$  = 1 mol. each of (*A*), (*D*), and (*E*), since the last are formed by polymerization of  $\text{HOCN}$ ; 2  $\text{COCl}_2$  = 1 mol. (*B*), and 3  $\text{COCl}_2$  = 1 mol. (*C*). The products of the reaction were estimated as follows, using I as example: The solid material was washed with PhH, dried, and extd. with warm alc.; the residue (lost 12.04 g.  $\text{NH}_4\text{Cl}$  on treatment with  $\text{H}_2\text{O}$ ) left 0.436 g. insol. matter, from which 0.4 g. (*C*) was extd. by  $\text{NaOH}$ , leaving 0.036 g. (*E*). The alc. ext., evapd. to small vol., yielded 2.25 g. crystals containing 0.96 g.  $\text{NH}_4\text{Cl}$ , 0.95 g. (*A*), and 0.34 g. of chiefly Et allophanate (*F*) and a trace of (*B*), while the filtrate, evapd. dry, left 2.45 g. residue; this was dissolved in 50 cc.  $\text{H}_2\text{O}$  and (*D*) estimated in an aliquot by titration with 0.1 *N*  $\text{NaOH}$ , with phenolphthalein as indicator, (*A*) by pptn. as nitrate, and (*B*) colorimetrically (*C. A.* 8, 1415). Absence of guanidine was proved by absence of pptn. with picric acid. The proportion of (*D*) was small owing to the unfavorable conditions for the existence of free  $\text{HOCN}$ . "After the crude product from expt. I had been shaken with a small quantity of pure alc. (*F*) (5.3% of the theoretical) was extd. from the PhH-alc. filtrate. This could only have resulted from a reaction with  $\text{HOCN}$  generated from the substance  $\text{H}_2\text{NCOCl}$ , present in the original product, thus:  $2 \text{H}_2\text{NCOCl} + \text{C}_2\text{H}_5\text{OH} \longrightarrow \text{C}_2\text{H}_5\text{O}_2\text{N}_2 + 2 \text{HCl}$ ." While the total Cl of the  $\text{COCl}_2$  was thus accounted for, only about 62% of the CO was recovered, owing to the decompn. of  $\text{COCl}_2$  by  $\text{H}_2\text{O}$  generated in the formation of (*C*). On adding 0.68 g.  $\text{NH}_3$  in 200 cc. PhH to 4 g.  $\text{COCl}_2$  in 100 cc. PhH, washing the ppt. with PhH, drying, and extg. with alc., 4.6% of the theory of (*A*) was found after removal of the  $\text{NH}_4\text{Cl}$ , while the PhH filtrate, shaken with a

constitution of dihydroanhydroberberine ((VI), using (II) as basis) (*Arch. Pharm.* 243, 35(1905); *C. A.* 5, 1601) are upheld against those of Faltis (*C. A.* 5, 1751), confirmation and additional evidence being obtained by the further study of this substance. For

preparative purposes (VI) is best prepd. as follows: 500 g. com. (II).HCl (berberinium chloride (7)) are thoroughly mixed with 700 cc. 30% aq. NaOH in a stout, round-bottomed flask, let stand 0.5 hr., suspended in a large basin of cold H<sub>2</sub>O, and this is heated so that it boils in about 0.5 hr., without stirring. After it is heated 1 hr. longer, with shaking, and let stand overnight the aq. alkali is run off from the solidified material, which is washed by decantation with H<sub>2</sub>O, mixed with excess of dil. HCl, heated on the H<sub>2</sub>O bath, and sucked off, the residue is ground up and the HCl treatment repeated until all base has been extd. and a nearly colorless mass of oxyberberine (8) remains. The exts. are mixed with concd. HCl while still hot; on standing (VI).HCl (9) seps., mixed with unchanged (7). The product is washed with dil. HCl, recrystd. by soln. in the minimum amt. of boiling H<sub>2</sub>O and adding concd. HCl, redissolved in hot H<sub>2</sub>O, and mixed with excess of NH<sub>3</sub>. After the semi-solid mass hardens it is ground up and washed with hot H<sub>2</sub>O until the filtrate is no longer dark (this deposits a deeply colored salt on standing which proved to be (7) containing a small amt. of an undetd. coloring matter), dried on tile, and triturated and washed first with MeOH and then with acetone until a red impurity has been removed; after 2 recrystns. from acetone the (VI) is quite pure. The acetone mother liquors are concd. and the residue worked up as was (9). The (VI) m. 168-70°; a mixt. with tetrahydroanhydroberberine (10) (m. 170°) softened 140-5°, m. 152°, so these cannot be identical, as claimed by F. (*loc. cit.*). In H<sub>2</sub>SO<sub>4</sub> (VI) gives a deep brown color on addition of a trace of dil. HNO<sub>3</sub>; it is unchanged by boiling with dil. HCl, differing from anhydromethylberberine (XI) (see below); contrary to G. (VI) and its salts are not readily oxidized on exposure to air, detailed expts. being given which show that (VI) was unaltered after 6 months, while (9),

which crysts. with 4  $\text{H}_2\text{O}$ , one of which remains at  $90^\circ$ , was only very slightly oxidized during 6 months. (10) may be obtained colorless, m.  $174^\circ$ , by recrystg. its hydrochloride (12) from HOAc until white, then liberating the base and recrystg. from alc. or acetone. Detailed crystallographic measurements of (VI) and (10) are given, affording further proof of their non-identity. Addition of excess of  $\text{Me}_2\text{SO}_4$  to a soln. of (VI) in boiling PhH results in the gradual deposition of *dihydroanhydroberberine methosulfate* (13),  $\text{C}_{28}\text{H}_{31}\text{O}_4\text{N} \cdot \text{Me}_2\text{SO}_4$ , better prepd. by shaking (VI) with 1.5 g.  $\text{Me}_2\text{SO}_4$  until pasty, letting stand 8 days, triturating with PhH, filtering, and recrystg. from MeOH; yellow prisms, sinters  $140^\circ$ , m. about  $205^\circ$ , seps. from  $\text{H}_2\text{O}$  as very voluminous needles with 4  $\text{H}_2\text{O}$ . Crystallographic measurements are given of the orthorhombic crystals from MeOH. The aq. soln. gives no ppt. even on boiling with aq.  $\text{NH}_3$ , but turns milky with hot, concd.  $\text{NaOH}$ , and gives a cryst. ppt. In HOAc it gives a pink color with  $\text{H}_2\text{SO}_4$ , changing through claret to brown with a drop. of dil.  $\text{HNO}_3$ . The PhH washings from the crude (13) and the mother liquors contain the more sol. *dihydroanhydroberberine methyl hydrogen sulfate* (14),  $\text{C}_{28}\text{H}_{31}\text{O}_4\text{N} \cdot \text{MeHSO}_4$ , amber prisms, gives (VI) on addition of  $\text{NH}_3$ . With boiling dil. KI a boiling, dil. soln. of (13) gives the methiodide, identical with that prepd. directly by Freund and Fleischer (C. A. 9, 2872); *methochloride* (13a), prisms with 5  $\text{H}_2\text{O}$ , 4 of which are lost at  $95^\circ$ , m.  $223^\circ$  (decompn.), gives (VI) when heated at  $230^\circ$  for several min., MeCl being eliminated (cf. [1873]). When 5 g. (13) free from (14) are dissolved in the minimum amt. of boiling MeOH, mixed with 30 cc. 25% MeOH-KOH, and boiled vigorously for 10 min. so that much of the MeOH escapes, an oil seps., after which the whole is vigorously shaken under cold  $\text{H}_2\text{O}$ ,  $\text{H}_2\text{O}$  is added, and the ppt. washed with  $\text{H}_2\text{O}$ , then ground and washed with MeOH. The resulting *anhydromethylberberine* (XI), using (II) as basis,  $\text{C}_{21}\text{H}_{21}\text{O}_4\text{N}$ , is rapidly recrystd. from MeOH or acetone, forming pale yellow needles or prisms, m.  $94-5^\circ$ , weakly basic, in HOAc gives a faint yellow-brown color with  $\text{H}_2\text{SO}_4$ , changing rapidly to green, and, on adding a trace of dil.  $\text{HNO}_3$ , cherry-red; with  $\text{PhN}_2\text{Cl}$  in HOAc it gives a deep orange-red color; when boiled with MeOH in the air and the soln. concd. a small yield of what was apparently *trioxanhydromethylberberine* (XV),  $\text{C}_{28}\text{H}_{29}\text{O}_7\text{N}$ , sepd., garnet prisms, m.  $153-5^\circ$ , feebly basic, is decompd. by boiling dil. HCl; in HOAc it becomes deep orange with  $\text{H}_2\text{SO}_4$ , changing to dark brown with a trace of  $\text{HNO}_3$ ; the resinous main product of the action of MeOH on (XI) yielded nothing cryst., this and the failure to isolate cryst. products analogous to the epicryptopines (157) by the action of concd. HCl being the chief points of departure of the properties of (XI) from those of anhydrocryptopine (16) (154). Analogous to this, when reduced in iced dil. HCl or  $\text{H}_2\text{SO}_4$  soln. with Na-Hg it yields N-methylisotetrahydroanhydroberberine (B) Pyman, C. A. 7, 2743; *hydriodide*, needles, darkens  $220^\circ$ , m.  $225^\circ$  (decompn.). 15 g. (XV), shaken with 20 cc.  $\text{Me}_2\text{SO}_4$  and let stand 1 week, gave, on triturating and washing with PhH and recrystg. from  $\text{H}_2\text{O}$ , *anhydromethylberberine methosulfate* (17), leaflets which weather in the air but retain 1  $\text{H}_2\text{O}$  at  $100^\circ$ , m.  $150-2^\circ$  with effervescence; in HOAc it gives a pink color with  $\text{H}_2\text{SO}_4$ , changing through blue to brown with a drop of dil.  $\text{HNO}_3$ ; dissolved in boiling MeOH and heated with MeOH-KOH it gives (XI) *methiodide*, flat prisms, browns  $185^\circ$ , m.  $188-90^\circ$  (decompn.). Like the methosulfate (154) of (16), when 1 g. (17) is boiled 5 min. with 3 cc. concd. HCl and the acid distd. off *in vacuo*, *ψ-methylberberinium chloride* (XVIII),  $\text{C}_{21}\text{H}_{20}\text{O}_4\text{NCl} \cdot \text{H}_2\text{O}$ , is obtained, seps. from  $\text{H}_2\text{O}$  contg. HCl as balls of needles or plates which retain 1  $\text{H}_2\text{O}$  at  $70^\circ$  *in vacuo*, softens  $80-2^\circ$ , sinters, and turns sirupy below  $100^\circ$ ; in HOAc it gradually gives a  $\text{KMnO}_4$  color with  $\text{H}_2\text{SO}_4$ ; a crystal, moistened with concd.  $\text{HNO}_3$ , gives a crimson soln.; an aq. soln. reduces  $\text{KMnO}_4$  instantly at  $0^\circ$  and turns yellow with  $\text{NH}_3$  but when warmed with NaOH the yellow soln. changes

through orange to brown and a greenish base seps.; *chloroplatinate* (19), pale salmon-colored, the filtrate being deep pink, just as in the prepn. of the same salt of  $\psi$ -cryptopine chloride (20) (155). (19) turns yellow 200°, gradually darkens, sinters above 210°, m. 243° (decompn.); *iodide*, almost colorless warts, darkens 160-5°, decomp. 175-80°. Just as dil. HCl acts on (16) to form the hydroxyisoanhydrodihydrocryptopines (A) (21) (156) and (B) (22) (156), (XI) yields the corresponding compds. as follows: 2 g. are mixed with 2.5 cc. concd. HCl and 8 cc. H<sub>2</sub>O and warmed in boiling H<sub>2</sub>O for 20 min. The sirup which seps. on cooling hardens and is dissolved in hot H<sub>2</sub>O, treated with NH<sub>3</sub>, and the ppt. either immediately extd. with Et<sub>2</sub>O from which (XXIII A) (see below) seps. on rapidly drying and cong., or dried on tile and triturated and washed with MeOH, the residue being *hydroxyisoanhydrodihydromethylberberine* (A) (XXIII), C<sub>21</sub>H<sub>22</sub>O<sub>4</sub>N, purified from MeOH, indefinite crusts, m. 210-12°, readily forms supersatd. solns. of sparingly sol. salts with mineral acids; in HOAc gives an orange color with H<sub>2</sub>SO<sub>4</sub>. The MeOH mother liquors from (XXIII A) are dild. with H<sub>2</sub>O and the ppt. is extd. with Et<sub>2</sub>O, which is washed, dried, and fractionally concd., the filtrate from the (XXIII A) obtained by the 1st method being worked up in the same way. By recrystn. from Et<sub>2</sub>O or MeOH these fractions are sepd. into pure (XXIII A) and *hydroxyisoanhydrodihydromethylberberine* (B) (XXIII), prisms, m. 168-70°, does not yield a cryst. hydrochloride. It has now been found possible to obtain a cryst. (21) by the 1st method for the isolation of (XXIII A); nodules, m. 177-80°, seps. from MeOH or acetone on long standing as micro-prisms. When 1 g. (XXIII A or B) is heated 15 min. at 100° with 2 cc. AcCl, the excess evapd. and the residue mixed with cold H<sub>2</sub>O and heated to boiling the viscid *hydrochloride* (24) of what is apparently the *acetyl derivative* (25) of (XXIII A) seps. (24), C<sub>21</sub>H<sub>23</sub>O<sub>4</sub>N.HCl, seps. from MeOH as doubly refracting rhombic plates of angle 78° and showing straight extinction, m. about 253° (decompn.); with NH<sub>3</sub> the hot aq. soln. yields (25), prisms from MeOH, m. 166-7°; the filtrate, on spontaneous evapn. deposits (XXIII A). Treated with NH<sub>3</sub>, the mother liquors and washings of (24) gave a ppt. of what seemed to be the *acetyl derivative* (26) of (XXIII B), nodules from MeOH, m. 213-5°; with warm, dil. HCl it gives the *hydrochloride* (27), rhombic plates of angle 70°, darkens above 220°, decomp. 230°, seps. from hot H<sub>2</sub>O as very characteristic, almost square plates with bevelled edges; the mother liquors from this deposit (24) on concn., interconversion apparently having taken place during the formation of (27). Boiled with 20% H<sub>2</sub>SO<sub>4</sub> for 10 min. and treated with NH<sub>3</sub>, crystg. the ppt. from MeOH, (26) gave (XXIII A),

while the filtrate deposited (XXIII B) on slow evapn. in the ice-box; boiled with 10% MeOH-KOH and the soln. concd. and let stand in the ice-box it gave (XXIII A). *Iso-anhydromethylberberine* (XXVIII),  $C_{21}H_{21}O_4N$ , analogous to isoaanhydrocryptopine (29) (156), may also be prepd. by the action of boiling concd. HCl on (XXIII A or B), but is best prepd. as follows: 2 g. (XXIII) are warmed with 6 cc.  $POCl_3$ , enough heat being evolved on soln. to raise the temp. from  $60^\circ$  to the b. p.; after boiling 10 min. and distg. off the excess  $POCl_3$  *in vacuo* the resulting yellow gum is dissolved in much boiling  $H_2O$ , the hydrochloride (30) of (XXVIII) sepg. on concg. and stirring; prisms, m. about  $205-10^\circ$ ; treated in boiling aq. soln. with  $NH_3$  it forms a milky liquid from which (XXVIII) soon crystals, prisms from MeOH, m.  $123-4^\circ$ ; in HOAc it gives an orange color with  $H_2SO_4$ , changing to brown with dil.  $HNO_3$ ; heated in a test tube it chars and gives a  $Me_2NH$ -like odor; hydriodide, indefinite nodules, discolors about  $215^\circ$ , de-comps. about  $247^\circ$ , is dimorphic, sepg. from alc. as needles and prisms, the former dissolving first on warming. When boiled with a large excess of dil.  $H_2SO_4$  (XXVIII) gives small yields of (XXIII A and B), isolated in the usual way. 30 g. (13a) were dissolved in 1 l. hot  $H_2O$ , mixed with 50 cc. concd. HCl, and heated to boiling in an enamelled basin, adding 1500 g. 3% Na-Hg in 3 portions and enough HCl to keep the reaction strongly acid; on adding  $NH_3$  to the cooled soln., drying the ppt. on porous tile, and extg. with ether, the residue was found to consist of a quaternary chloride, more being obtained from the aq. washings of the crude ppt. above. By repeated crystn. from dil. HCl the salt was sepd. into the  $\alpha$ - and  $\beta$ -methochlorides (stereoisomeric) of tetrahydroanhydroberberine (Pyman, *loc. cit.*). The  $Et_2O$  ext. from the crude quaternary chloride (above) was well washed with  $H_2O$ , dried over  $K_2CO_3$ , and evapd., yielding the sirupy *dihydromethylisotetrahydroanhydroberberine* (XXXI) (cf. Pyman, *loc. cit.*),  $C_{22}H_{25}O_4N$ , whose salts show little tendency to cryst.; *chloroplatinate*, chalky, salmon-colored; *methosulfate*, pptd. as a sirup from PhH soln. by dry  $Et_2O$ , when dissolved in a little MeOH and boiled with excess MeOH-KOH for 15 min., letting most of the MeOH boil away, gave a caseous ppt. on adding  $H_2O$ . When this was extd. with much  $Et_2O$  and this dried and evapd. the resulting sirup gradually crystd. and was purified by soln. in dil. HCl, making alk. with  $NH_3$ , and repeating the process; the resulting *dihydrodimethylisotetrahydroanhydroberberine* (XXXII),  $C_{22}H_{27}O_4N$ , analogous to anhydrotetrahydromethylcryptopine (33) (149), could not be recrystd.; *chloroplatinate*, pale ochreous, *methosulfate* (34), prepd. in PhH soln., needles. When digested on the  $H_2O$  bath with a large excess of 20% MeOH-KOH (34) is readily de-compd. with elimination of  $NMe_3$ . After 20 min., when most of the MeOH is distd. off,  $H_2O$  is added and the caseous ppt. extd. with much  $Et_2O$ ; when this is dried, concd., and let stand, *berberidene* (XXXV),  $C_{20}H_{21}O_4$ , seps., analogous to cryptopidine (36) (151); prisms, m.  $113-4^\circ$ , seps. from MeOH as irregular laminae with lilac fluorescence. 2.3 g. (XXXV) were oxidized in 60 cc. acetone with 4 g. finely sieved  $KMnO_4$ , adding this gradually and keeping the temp. below  $18^\circ$ . The  $MnO_2$  ppt. was filtered off and washed with acetone, this yielding, on evapn., 1.2 g. of a sirup which gradually crystd.

This was distd. with steam and the distillate extd. with  $Et_2O$  and the ext. washed, dried, and evapd., yielding long needles of 2,5,6-(OH)(MeO) $_3C_6H_2Me$  (37) (150).

The portion non-volatile with steam was extd. with  $\text{Et}_2\text{O}$ , this yielding a *ketodihydroberberidine* (XXXVIII)  $\text{C}_{20}\text{H}_{20}\text{O}_5$ , on evapn., allowing to solidify, triturating with MeOH, and recrystg. from HOAc; faintly yellow plates, m.  $118-20^\circ$ ; a crystal is colored crimson by concd.  $\text{HNO}_3$  and gives a brown color in HOAc with  $\text{H}_2\text{SO}_4$ ; *semicarbasone*,  $\text{C}_{20}\text{H}_{20}\text{O}_4\text{N}_2$ , nodules from MeOH, m. and effervesces  $218-20^\circ$ . The  $\text{MnO}_2$  ppt. from the oxidation of (XXXV) was repeatedly extd. with small amts. of boiling  $\text{H}_2\text{O}$ , and the soln. concd. and acidified with HCl; the viscid ppt. (about 1 g.) was boiled with 200 cc.  $\text{H}_2\text{O}$ , filtered from tar, and the tar warmed with dil.  $\text{NH}_3$ , the soln. boiled with bone-black, and filtered. The acid was again pptd. and boiled with 100 cc.  $\text{H}_2\text{O}$  and the 2 aq. exts. were combined, neutralized with  $\text{Na}_2\text{CO}_3$ , mixed with bone-black, evapd. to about 20 cc., and filtered. On acidifying and recrystg. from HOAc 5,6-dimethoxy-*o*-toluic acid (39) (151) was obtained, the m. p. of this after repeated recrystn. from HOAc being  $184^\circ$  instead of  $177^\circ$ ; the mother-liquors from the purification of this were concd. *in vacuo* until nearly dry, mixed with sand, and extd. with  $\text{Et}_2\text{O}$  in a Soxhlet, the  $\text{Et}_2\text{O}$  yielding a small cryst. residue which was sepd. by crystn. from HCl into (39) and a more sol. acid sepg. from a little  $\text{H}_2\text{O}$  as hexagonal plates, m. about  $171-4^\circ$ , and yielding an anhydride m. about  $170-3^\circ$ , gave a negative Zeisel detn., and appears to be hydrastic acid,  $\text{CH}_2:\text{O}:\text{C}_6\text{H}_3(\text{CO}_2\text{H})_2(o)$ . (8) was reduced to (10) as follows: 10 g. (8), suspended in 260 cc. 97% alc., were gradually mixed with 130 cc. 97%  $\text{H}_2\text{SO}_4$ , the heat generated causing complete, permanent soln. of the (8). The electrolytic cell was a glass jar 20 cm. high, of 1 l. capacity; the cathode a sheet of Pb fitting around the inside and coated with electrolytic Pb; the anode, a strip of Pb, was placed in a porous cell 5 cm. in diameter, contg. 20%  $\text{H}_2\text{SO}_4$  which was replenished from time to time. The soln. was placed in the cathodic compartment and a current of 6 amps. passed for 48 hrs. After mixing with about 500 g. ice and  $\text{H}_2\text{O}$  and letting stand 24 hrs. a gray ppt. (5.3 g.) consisting partly of (8) was filtered off and an excess of  $\text{NH}_3$  added to the filtrate. The dark ppt. (4.6 g.) was dried, digested with a little MeOH to remove most of the color dissolved in boiling, very dil. HCl, bone-blackd, and the soln. concd., (10).HCl sepg. on keeping and becoming colorless on recrystn. from HOAc.

M. HEIDELBERGER.

**Morindone.** JOHN LIONEL SIMONSEN. *J. Chem. Soc.* 113, 766-74(1918).—Morindone (A) occurs in the root bark of *Morinda citrifolia* and *M. umbellata* chiefly as the glucoside morindin (B). *M. citrifolia* was used in the present work and the (B) extd. and purified essentially as given by Perkin and Hummel (*J. Chem. Soc.* 65, 851(1894)). After repeated crystn. from 75% alc. it seps. as voluminous, yellow needles, m.  $250-1^\circ$  when rapidly heated, sinters  $235^\circ$ , m.  $245^\circ$  when slowly heated. P. and H.'s formula,  $\text{C}_{20}\text{H}_{22}\text{O}_{14}$ , was confirmed, as against that of Oesterle and Tisza,  $\text{C}_{27}\text{H}_{30}\text{O}_{18}$  (*C. A.* 2, 830, 1997). Octaacetyl morindin (C), from (B) and  $\text{Ac}_2\text{O}$ , boiled with a trace of  $\text{C}_6\text{H}_5\text{N}$  for 2 hrs., m.  $239-40^\circ$  (P.,  $246-8^\circ$ ; O.,  $236^\circ$ ) and does not contain 9 Ac groups (O.). Since P. used *M. umbellata* and O. used *M. citrifolia* there appears to be no difference between the (B) isolated from the 2 sources in spite of the discrepancies in the work of these authors. Hydrolyzed with alc.  $\text{H}_2\text{SO}_4$  (B) yields (A), which is not attacked when heated at  $100^\circ$  with  $\text{AcOH-HBr}$  satd. at  $0^\circ$ , and remains unaltered when air is drawn through its alk. soln. for some days; heated 2 hrs. with  $\text{Ac}_2\text{O}$  and  $\text{NaOAc}$  it gives the triacetyl deriv. (D), pale yellow needles, sinters slightly above  $243^\circ$ , m.  $249^\circ$  (not  $222^\circ$  (P.)); it is not readily attacked by  $\text{CrO}_3$ , and attempts to oxidize the Me group with  $\text{CrO}_3$  failed, part of the (D) being completely destroyed and the rest unattacked; did not yield a Br deriv. at  $100^\circ$  with  $\text{AcOH-HBr}$  satd. at  $0^\circ$  as would have been the case if the group  $\text{CH}_3\text{OAc}$  had been present (cf. P., Thorp's "Dictionary of Applied Chem." III, 547). By the  $\text{C}_6\text{H}_5\text{N}$  method (A) yields the *tribenzoate* (E),  $\text{C}_{28}\text{H}_{28}\text{O}_8$ , yellow needles, m.  $218-9^\circ$ . The difficult complete methylation of (A) was

finally accomplished as follows: 3 g. (A) were mixed with a soln. of 12 g. KOH in 15 cc. H<sub>2</sub>O and 15 cc. Me<sub>2</sub>SO<sub>4</sub> added all at once. After vigorous stirring, the same amts. of KOH and Me<sub>2</sub>SO<sub>4</sub> were added and the deep red alk. soln. was boiled, acidified, and the crude product again methylated as before. The soln., containing in suspension a sparingly sol., red K salt (see below) and morindone trimethyl ether, C<sub>18</sub>H<sub>18</sub>O<sub>8</sub>, (F), was filtered, and the ppt. boiled 4 times with dil. alkali and then ground with a large vol. of CHCl<sub>3</sub>, which removed the (F), leaving the red salt. The CHCl<sub>3</sub> was evapd., the residue dissolved in hot C<sub>7</sub>H<sub>8</sub>, and the soln. washed with hot, dil. alkali to remove more of the partially methylated product. After filtering and blowing off the C<sub>7</sub>H<sub>8</sub> with

steam the (F) was obtained by recrystn. from HOAc; it had the properties given by O. and T. It dissolves in H<sub>2</sub>SO<sub>4</sub> with a blue color, behaves like (D) with CrO<sub>3</sub>, but is slowly oxidized when boiled in dil. Na<sub>2</sub>CO<sub>3</sub> suspension with KMnO<sub>4</sub>, only (CO<sub>2</sub>H)<sub>2</sub> being recovered, as was also the case when HNO<sub>3</sub> was used. The red K salt (see above) was suspended in hot H<sub>2</sub>O, decompd. with HCl, and the brown solid repeatedly recrystd. from HOAc; the *morindone monomethyl ether* (G), C<sub>14</sub>H<sub>14</sub>O<sub>6</sub>, forms brown, iridescent needles, m. 248°, gives a slightly redder color than (A) in H<sub>2</sub>SO<sub>4</sub>, changing to greenish red with a crystal of KNO<sub>3</sub>; dissolves in fuming HNO<sub>3</sub> with a transient red color, changing to red-brown; the solns. of the red K and Na salts are slightly fluorescent. (G) is readily attacked by alk. KMnO<sub>4</sub>, apparently undergoing complete disintegration, this indicating that the methylated OH is in the same ring as another OH group. 0.1 g. (G) was also obtained when 0.5 g. (A) were mixed with NaOMe (1.3 g. Na) and 0.8 g. MeI and heated at 100° for 8 hrs., poured into H<sub>2</sub>O, made alk. with KOH, and the mixt. boiled, filtered, and the residual K salt washed with hot, dil. alkali until the washings were only faintly colored. Heated 2 hrs. with Ac<sub>2</sub>O and NaOAc (G) gives *diacetylmorindone monomethyl ether*, C<sub>20</sub>H<sub>18</sub>O<sub>7</sub>, yellow prisms, m. 245–6°. The sugars from the hydrolysis of (B) were not characterized, only small amounts of 2 osazones being obtained, m. 207° and 195°, resp. The behavior of (A) on attempted oxidation indicates that the Me is *o*- to 1 of the OH groups, corroborative evidence being seen in the fact that *o*-MeC<sub>6</sub>H<sub>4</sub>OMe does not yield the CO<sub>2</sub>H compd. with CrO<sub>3</sub> in AcOH. Of the 4 possible trihydroxy-2-methylanthraquinones in which an OH is *o*- to the Me (I) and (II) are considered the most likely for (A), since S. believes that steric hindrance would prevent MeI from reacting with the others; the fact that only a mono-Me deriv. is obtained with MeI indicates that 2 of the OH groups are *o*- to the CO groups, and since (A) is a mordant dye resembling alizarin, it is possible that 2 OH groups are in the 1,2-positions. (A) cannot be a deriv. of anthragallol or purpurin, since it is not oxidized by air in alk. soln. (I) is considered more probable than (II), since in its color reactions (A) resembles hydroxyanthrarufin more closely than hydroxychrysazin.

M. HEIDELBERGER.

**Nitration of 2- and 6-methoxy-*m*-tolualdehydes and *m*-toluic acids.** JOHN LIONEL SIMONSEN. Madras. *J. Chem. Soc.* 113, 775–82(1918).—Expts. made in the course of an attempt to synthesize 3,4-MeO(Me)C<sub>6</sub>H<sub>3</sub>(CO<sub>2</sub>H)<sub>2</sub>(*o*-) with a view to prepg. anthraquinone derivs. 10 g. 2,3-HO(Me)C<sub>6</sub>H<sub>3</sub>CHO were dissolved in NaOMe (2 g. Na) and treated with 15 g. Me<sub>2</sub>SO<sub>4</sub>, the addition of NaOMe and Me<sub>2</sub>SO<sub>4</sub> being repeated 3 times, finally heating 15 min. on the H<sub>2</sub>O bath, adding H<sub>2</sub>O, extg. with Et<sub>2</sub>O, and drying and evapg. the ext.; the 2-methoxy-*m*-tolualdehyde (A) b<sub>4</sub> about 120°, viscid,

pleasant-smelling oil, giving a cherry-red color with  $\text{H}_2\text{SO}_4$ ; *oxime*, needles, m.  $118^\circ$ ; *semicarbazone*, needles, m.  $224^\circ$ . 2 g. (A) were added gradually to 10 g.  $\text{HNO}_3$  (d. 1.52), cooling with ice. After 15 min. the mixt. was poured on to ice, and the rapidly solidifying oil triturated with dil. aq.  $\text{Na}_2\text{CO}_3$  to remove a trace of 5-nitro-2-methoxy-m-toluic acid (B), dried on tile, and recrystd. from  $\text{Et}_2\text{O}$ -petr. ether; the 5-nitro-2-methoxy-m-tolualdehyde (C), 2,3,5-MeO(Me)( $\text{O}_2\text{N}$ ) $\text{C}_6\text{H}_3\text{CHO}$ , forms needles, m.  $61-2^\circ$ ; *semicarbazone*, needles, m.  $233^\circ$ . 0.5 g. (C) in 5 cc. warm MeOH, mixed with 0.5 g. acetone, and heated to boiling for a few min. after adding 2 drops 50% KOH, gave 5,5'-dinitro-2,2'-dimethoxy-di-3-m-methylstyryl ketone, yellow needles, decomp.  $252^\circ$ . (B) is more easily obtained by dissolving 1.2 g. (C) in 30 cc. acetone and gradually adding 0.65 g. powdered  $\text{KMnO}_4$ , then adding  $\text{H}_2\text{O}$ , boiling, filtering off the  $\text{MnO}_2$ , concg. until free from acetone, removing a trace of unchanged (C), and acidifying; it forms needles, m.  $154^\circ$ ; *silver salt*, pale yellow needles. (B) was also prepd. by methylation of the corresponding OH acid (Einhorn and Pfyl, *Ann.* 311, 47(1900)). Oxidation of (A) in acetone by  $\text{KMnO}_4$  gave 2-methoxy-m-toluic acid,  $\text{C}_8\text{H}_9\text{O}_3$ , needles, m.  $83^\circ$ ; *silver salt*, caseous ppt.; nitrated at  $30^\circ$  with 3 parts  $\text{HNO}_3$  (d. 1.52) it gives (B). 3 g. 3,6-(CHO)(MeO) $\text{C}_6\text{H}_3\text{Me}$  were slowly added to 9 g.  $\text{HNO}_3$  (d. 1.52), cooling with ice-salt, pouring on to ice after 10 min.; the resulting 5-nitro-6-methoxy-m-tolualdehyde (D), 3,5,6-(CHO)( $\text{O}_2\text{N}$ )(MeO) $\text{C}_6\text{H}_3\text{Me}$ , forms needles, m.  $77^\circ$ ; *semicarbazone*, needles, decomp.  $235^\circ$ ; 5,5'-dinitro-4,4'-dimethoxydi-3-methylstyryl ketone, yellow needles, m.  $214^\circ$ . 5-Nitro-6-methoxy-m-toluic acid (E), softens  $175^\circ$ , m.  $180-1^\circ$ ; *calcium* and *barium* salts, needles; *methyl ester*, needles, m.  $47^\circ$ . When gradually added to 3.5 parts  $\text{HNO}_3$  (d. 1.52) at  $30-5^\circ$  3,6-( $\text{HO}_2\text{C}$ )(MeO) $\text{C}_6\text{H}_3\text{Me}$  gives (E), extd. from the crude product by dil. aq.  $\text{Na}_2\text{CO}_3$ , and a neutral substance, apparently 6-nitro-o-tolyl methyl ether, 2,6-MeO( $\text{O}_2\text{N}$ ) $\text{C}_6\text{H}_3\text{Me}$ , needles, m.  $69^\circ$ , only slightly attacked by hot, alk.  $\text{KMnO}_4$ , but when 0.25 g. was dissolved in 1 cc.  $\text{H}_2\text{SO}_4$  and gradually treated with a soln. of 0.3 g.  $\text{CrO}_3$  in 2 cc.  $\text{H}_2\text{SO}_4$ , followed by the addition of  $\text{H}_2\text{O}$ , what appeared to be 6-nitro-2-methoxybenzoic acid pptd., needles, m.  $161^\circ$ , purified by dissolving in dil. aq.  $\text{Na}_2\text{CO}_3$ , filtering from unattacked material, and pptg. with acid. While S. and Rau's suggestion (C. A. 11, 1950) as to the orientating effect of negative groups o- to positive groups appears to hold in the case of the nitration of  $\text{AcNH-MeO}$  derivs. it does not seem to be of general application, as 6- $\text{NO}_2$  derivs. were to be expected in this case.

M. HEIDELBERGER.

**N-Acyl derivatives of carbazole.** MAURICE COPISAROW. Univ. Manchester. *J. Chem. Soc.* 113, 816-20(1918).—It has been possible to extend the list of the few substances of this class known by improving upon the unsatisfactory methods at present available (references given). The present method depends upon the trituration of K carbazole (A) with gradual additions of the acid chloride, added in slight excess. After 2 hrs. the mixt. is extd. with  $\text{H}_2\text{O}$ , dil.  $\text{Na}_2\text{CO}_3$ , and  $\text{H}_2\text{O}$ , and finally dried. *N*-Acetylcarbazole (Böeseken, C. A. 7, 1179); *N*-benzoylcarbazole. *N*-Phenoxyacetylcarbazole, needles from alc., decomp.  $121-2^\circ$  with regeneration of carbazole (B); *N*-nonoylcarbazole, needles from alc., m.  $72-3^\circ$ , gives (B) on heating above its m. p.; *N*-palmitylcarbazole, keeping the reaction mixt. at  $75^\circ$  for 2 hrs., with occasional trituration, needles from alc., m.  $90-1^\circ$ , rhombs from PhH. When dry  $\text{COCl}_2$  was passed over finely powdered (A), regulating the current of gas so as to keep the temp. of the energetic reaction at  $150-60^\circ$ , *N*-carbonylcarbazole was obtained,  $(\text{C}_{12}\text{H}_8\text{N})_2\text{CO}$ , purified by fractional crystn. from alc., the 1st crop being mainly (B); after 3 crystns. from alc. it forms needles, m.  $181-3^\circ$ ; condensation between (A) and  $\text{COCl}_2$  fails to take place even in boiling  $\text{C}_6\text{H}_{10}$  (cf. also Paschkowetzky, *Ber.* 24, 2905(1891) who used PhH). *N*-Oxalylcarbazole (C),  $(\text{C}_{12}\text{H}_8\text{N.CO})_2$ , prepd. as in the case of the monobasic derivs., rhombs from  $\text{PhNO}_2$  or  $\text{CS}_2$ , m.  $265-6^\circ$ , is the only one of the acyl deriva.

which does not give in  $\text{H}_2\text{SO}_4$  soln. the green color with concd.  $\text{HNO}_3$  characteristic of (B) and many of its derivs.; heated above  $200^\circ$  or fused above  $200^\circ$  with a large excess of  $(\text{CO}_2\text{H})_2$ , no "carbazole blue" is formed, nor is the dye formed when the product of the reaction between  $(\text{COCl})_2$  and (B) is heated above  $200^\circ$ , this showing that (C) cannot be regarded as an intermediate step in the formation of the dye, which is prepd. by the fusion of (B) with  $(\text{CO}_2\text{H})_2$  (Suida, *Ber.* 13, 1403(1879); Bamberger and Müller, *Ber.* 20, 1903(1887)).

M. HEIDELBERGER.

**The boiling points of the paraffins.** GERVAISE LE BAS. *Chem. News* 117, 241-2 (1918).—According to Hinrichs and Naumann, the more considerable the branching of the chain of a compd. or, on the other hand, the more compact the mol., the lower is the b. p. The author shows, however, that for paraffins, diminution of the b. p. depends on the substitution of the  $\beta$ ,  $\gamma$ , and  $\delta$  C atoms by Me groups. The assumption of two similar Me groups, attached to one C atom in the formula of iso compds. of the type  $\text{Me}_2\text{CR}$  is not true from the point of view of b. ps. which involves the substitution of the H of  $\alpha$ ,  $\beta$ ,  $\gamma$ ,  $\delta$  C atoms of the hydrocarbon chain by a single Me group. The difference in b. p. due to this structure is  $6-7^\circ$  when substitution of the  $\beta$ -methylene group has been effected and  $9^\circ$  when the  $\gamma$ -methylene group has been substituted. A table is given showing the effect of substitution of the Me group in paraffins on the b. p. Thus, *n*-hexane b.  $69^\circ$ ; the b. p. of  $\text{Me}_2\text{CHPr}$  ( $\beta$ -substitution) is  $62^\circ$ , a difference of  $-7^\circ$ , while the b. p. of  $\text{EtCHMeEt}$  ( $\gamma$ -substitution) is  $60^\circ$ , a difference of  $-9^\circ$ . Where two or three substitutions occur, the diminution of the b. p. is proportionately great. Evidence in favor of the view that the diminutions are connected with substitution of hydrocarbon chains by Me groups is that the diminution almost disappears when the Me group is replaced by one of greater complexity. When the  $\beta$ -methylene group is substituted by two Me groups, the number to be counted is three or four as the case may be, never two. The causes of the above changes may be that the presence of Me groups diminishes the residual affinity, or the intermol. cohesion. Two contiguous Me groups cause a rise in b. p. owing to their mutual action in increasing the residual affinity or intermol. cohesion.

C. H. KIDWELL.

**The mechanism of the electrochemical synthesis of carbamide.** FR. FICHTER. *Basel. Z. Elektrochem.* 24, 41-5(1918); *J. Chem. Soc.* 114, I, 215-6.—By a series of expts. F. shows that the electrochem. synthesis of carbamide from a soln. of  $(\text{NH}_4)_2\text{CO}_3$  (Drechsel, *J. prakt. chem.* 22, 476) is due to an oxidizing anodic reaction and is not a specific a. c. reaction. Former hypotheses are inadequate since the synthesis may be also carried out by adding to an ice-cooled, concd.  $\text{NH}_3$  soln. of a mixt. of  $(\text{NH}_4)_2\text{CO}_3$  and  $\text{NH}_2\text{CO}_2\text{NH}_4$  such oxidizing agents as  $\text{Ca}(\text{MnO}_4)_2$ ,  $\text{H}_2\text{O}_2$ , and ozonized  $\text{O}_2$ . The chief reaction is the oxidation of  $\text{NH}_3$  to  $\text{NH}_4\text{NO}_2$  or  $\text{N}_2$  and to  $\text{NH}_4\text{NO}_3$ . Heat set free at the anode or at the surface of contact with the oxidizing reagent, during the oxidation, is removed by external cooling to prevent loss of  $\text{NH}_3$ . By this local heating of the soln. some  $(\text{NH}_4)_2\text{CO}_3$  is converted into  $\text{CO}(\text{NH}_2)_2$ . The formation of carbamide by this anodic and oxidizing process is similar to that occurring in the living organism. The following equations express the formation of carbamide from  $(\text{NH}_4)_2\text{CO}_3$  or  $\text{NH}_2\text{CO}_2\text{NH}_4$ :

Since  $(\text{NH}_4)_2\text{CO}_3$  cannot exist in the presence of  $\text{H}_2\text{O}$  at and above  $135^\circ$ , only the right half of the equation is operative at and above that temp.; equil. shifts to the right as the temp. falls. Below  $135^\circ$  an increasing proportion of the  $(\text{NH}_4)_2\text{CO}_3$  is converted into the more stable carbamate. Addition of  $\text{H}_2\text{O}$  is necessary to prevent the withdrawal of  $(\text{NH}_4)_2\text{CO}_3$  from the reaction. The lower the temp., the greater the amt. of  $\text{H}_2\text{O}$  necessary to make the formation of carbamide possible. Solns. containing 1 mole of  $(\text{NH}_4)_2\text{CO}_3$  and 9 moles of  $\text{H}_2\text{O}$  serve best for carbamide production. If the

local temp. elevation does not exceed  $100^{\circ}$ , calcns. of the yield of carbamide do not contradict the hypothesis, inasmuch as the actual yields are much below the calcd. values. The above results show that from  $(\text{NH}_4)_2\text{CO}_3$  only, is the direct formation of carbamide possible.

C. H. KIDWELL.

**The transformation of methyl  $\alpha$ -eleostearate into methyl  $\beta$ -eleostearate.** R. S. MORRELL. *J. Soc. Chem. Ind.* 37, 181-2T(1918).—Chinese wood oil, d. 0.944,  $n_D^{15}$  1.5171 ( $12.5^{\circ}$ ), was thickened at  $240^{\circ}$  for 20 min., cooled rapidly, and treated with acetone. The thickened oil had d. 0.9638 ( $15^{\circ}$ ) and a mol. wt. of 1431 (in  $\text{C}_6\text{H}_6$ ). Both the sol. (polymerized) part "A" and the insol. part "B" were transformed into Me esters by NaOMe (Bull's method). The Me ester from "A" had  $d_{10}^{20}$  0.9159,  $n_D^{10}$  1.4958, mol. wt. (in  $\text{C}_6\text{H}_6$ ) 300; I value 151.8 (1.5 hrs.), 178 (6 days). The Me ester from "B" had  $d_{10}^{20}$  0.936;  $n_D^{10}$  1.49850; I value 138 (1.5 hrs.), 168 (6 days); mol. wt. ( $\text{C}_6\text{H}_6$ ) 393. The Me esters were fractionated under 10 mm. The Me ester from "A," redistd. between  $209^{\circ}$  and  $224^{\circ}$  and sapon. in the cold, gave an acid, m.  $66-9^{\circ}$ , which on thrice recrystg. from 60% alc. gave  $\beta$ -eleostearic acid,  $\text{C}_{18}\text{H}_{32}\text{O}_2$ , m.  $71-2^{\circ}$ , I value 172. The Me ester from "B" treated the same way gave an acid of practically the same properties. Examn. of the Ce salt from the undistd. Me ester obtained from "A" showed that  $\alpha$ -acid was present almost entirely and no  $\beta$ -acid. The conclusion is drawn that stereoisomeric change has occurred during distn. of the ester although NaOMe or polymerization may be factors in the transformation of Me  $\alpha$ -eleostearate into the  $\beta$ -ester.

C. H. KIDWELL.

**Constitution of the true nucleic acids.** R. FEULGEN. *Z. physiol. Chem.* 101, 288-95(1918); *J. Chem. Soc.* 114, I, 413.—A theoretical paper in which the general arrangement of the nucleotides in nucleic acid suggested by Levene is accepted, though the precise method of linking together of the nucleotides is regarded as unsettled.

C. J. WEST.

**Preparation and properties of thymic acid.** R. FEULGEN. *Z. physiol. Chem.* 101, 296-309(1918); *J. Chem. Soc.* 114, I, 413.—Thymic acid is prepd. by treating Na nucleinate with a slight excess of  $\text{H}_2\text{SO}_4$  and keeping the mixt. for 40 minutes at  $80^{\circ}$ . The acid is sepd. in the form of its Ba salt, and on hydrolysis yields cytosine and thymine.

C. J. WEST.

**Sitosterol.** A. WINDAUS AND ERIK RAHLEN. *Z. physiol. Chem.* 101, 223-35; *J. Chem. Soc.* 114, I, 388-9.—In the presence of Pd, sitosterol in AcOH soln. is reduced by H at  $100^{\circ}$ , forming *sitostanol*,  $\text{C}_{27}\text{H}_{48}\text{O}$ , flat 4- or 6-sided plates from alc., m.  $137^{\circ}$ ,  $[\alpha]_D^{20}$   $27.9^{\circ}$ ; acetate, m.  $132^{\circ}$ . The new compd. closely resembles cholestanol and on oxidation with  $\text{CrO}_3$  yields *sitostanone*,  $\text{C}_{27}\text{H}_{46}\text{O}$ , plates from alc., m.  $157^{\circ}$ ,  $[\alpha]_D^{20}$   $45.7^{\circ}$ , and with excess of  $\text{CrO}_3$ , *sitostandicarboxylic acid*,  $\text{C}_{27}\text{H}_{44}\text{O}_4$ , plates from AcOH, m.  $225-7^{\circ}$ . Both the latter compds. are analogous to, but not identical with, the corresponding derivs. cholestanol, and cholestandicarboxylic acid. On distn. of a mixt. of sitostandicarboxylic acid and  $\text{Ac}_2\text{O}$  at  $280^{\circ}$  in a vacuum,  $\text{CO}_2$  and  $\text{H}_2\text{O}$  are evolved and a *cyclic ketone* is produced,  $\text{C}_{26}\text{H}_{44}\text{O}$ , well-formed hexagonal crystals from MeOH, m.  $112^{\circ}$ . Reduction of sitostanone with Zn-Hg in boiling AcOH soln. yields the hydrocarbon, *sitostan*,  $\text{C}_{27}\text{H}_{48}$ , m.  $85-5.5^{\circ}$ , which resembles cholestan (m.  $80-1^{\circ}$ ), but is certainly not identical with it. The observed difference between these derivs. of sitosterol and the corresponding ones derived from cholesterol indicate that the general resemblance of the parent substances cannot be ascribed to the possession of a common structure with a difference in the position of the HO radical, the double linking or both. The difference between sitosterol and cholesterol must therefore be structural or steric.

C. J. WEST.

**Dissociation as a general phenomenon with hydrocarbons.** HANS MEYER AND ALICE HOFMANN. *Monatsh.* 39, 107-28(1918); *J. Chem. Soc.* 114, I, 383.—The ob-

served action of heat on org. substances, particularly hydrocarbons, indicates the occurrence of dissociation of H from C at a C-H linking; the effect is not appreciable at the ordinary temp., but becomes so when the dissociation pressure is favored by rise of temp., the influence of light and of electrical or radioactive radiation. Substances which will remove one or other of the products of the dissociation should also extend its effect, and examples are quoted in which oxidation is already known to cause a condensation of 2 aromatic nuclei. The general evidence supplied by the nature of the constituents of coal tar supports the further view that in pyrogenic reactions long side chains tend to become shortened, and this accords well with the fact that longer chains are more easily attacked, for example, by oxidizing agents. An examn. of anthracene revealed the presence of diphenyl, together with a mixture of the ditolyls, but dibenzyl could not be detected. Isopropylbenzene when heated strongly decomps. mainly into  $C_7H_8$  and  $(HCHO)_2$ , the latter arising from the severed methylene groups. Me phthalate gives  $PhCO_2Me$ ,  $HCHO$  and Me diphenyltricarboxylate.  $AcOMe$  gives  $\alpha$ -trioxymethylene as the main product and no Et succinate. The action of sunlight on a suspension of Et dihydrolutidinedicarboxylate in  $C_6H_6$  gives Et lutidinedicarboxylate.

C. J. WEST.

**Lignin.** I. Lignosulfonic acid. M. HÖNIG AND JACQUES SPITZER. *Monatsh.* 39, 1-14 (1918); *J. Chem. Soc.* 114, I, 375.—The lignosulfonic acid obtained from different sulfite liquors varies considerably in compn. and consists of a mixt. of substances. By fractional pptn. of the Ca salt or Ba salt from aqueous soln. by alc., it is possible to obtain fractions of distinct compn. approximating, for the Ba salt, to the formulas  $C_{20}H_{20}O_{11}S_2Ba$ ,  $C_{28}H_{24}O_{12}S_2Ba$ , and  $C_{74}H_{114}O_{48}S_2Ba$ .

C. J. WEST.

The configuration of organic compounds and their relation to chemical and physical properties. II. ARTHUR MICHAEL. *J. Am. Chem. Soc.* 40, 1674-707 (1918); cf. *C. A.* 12, 908.—In the present paper the physical and chem. properties of the stereomeric unsatd. acids are coordinated with the configurations given in the first paper, as far as exptl. evidence permits, and previous views in this field are critically revised. Of the physical properties, density, soly., m. p., b. p., viscosity, optical activity, magnetic rotation and heat of combustion are discussed; of the chem. properties, addition, elimination, substitution, anhydride formation, stereomutation, catalysis and esterification are taken up. No new exptl. data are given.

C. A. R.

**Effect of sodium on mixtures of malonic and succinic esters.** GERALD E. K. BRANCH AND H. E. HUDSON BRANCH. *J. Am. Chem. Soc.* 40, 1708-13 (1918).—Equimol. mixts. of malonic and succinic esters heated with Na gave chiefly succinosuccinic ester; when a large excess of malonic ester was used phloroglucinoltricarboxylic ester was found; by using succinosuccinic and malonic esters malonylsuccinic ester was obtained. The results are explained by Dieckmann's theory that the acetoacetic ester condensation is reversible.

CHAS. A. ROUVILLER.

**Proteinogenous amines.** I. Synthesis of  $\beta$ -imidazolyethylamine (histamine). KARL K. KOESSLER AND MILTON TH. HANKE. *J. Am. Chem. Soc.* 40, 1716-26 (1918).—In the main Pyman's method (*C. A.* 5, 3047) was followed but several additions and improvements have been made and a detailed account of the steps involved is given. Starting with 4530 g. citric acid, the following approximate average amts. of the various products involved in the synthesis can be obtained. Acetonedicarboxylic acid, 3300; diisonitrosoacetone, 1089; diaminoacetone chlorostannite, 2640; diaminoacetone hydrochloride, 1200; 2-thiol-4-aminomethylglyoxaline hydrochloride, 950; 4-hydromethylglyoxaline picrate, 1670; hydrochloride, 740; 4-chloromethylglyoxaline hydrochloride, 700; 4-cyanomethylglyoxaline, 200; imidazolyethylamine dihydrochloride, 165 g.

CHAS. A. ROUVILLER.

**Electronic constitutions of acetoacetic and citric acids and some of their derivatives.** MILTON T. HANKE AND KARL K. KOESSLER. *J. Am. Chem. Soc.* 40, 1726-32 (1918).—When citric acid (a) is treated with fuming  $\text{H}_2\text{SO}_4$ , the central  $\text{CO}_2\text{H}$  group is removed as  $\text{CO}$ , with formation of  $\text{CO}(\text{CH}_2\text{CO}_2\text{H})_2$  (b); the reason for this selection of the central  $\text{CO}_2\text{H}$  group must be due to a difference in the direction of the valence force holding this group from that holding the 2 end  $\text{CO}_2\text{H}$  groups. The addition reactions of  $\text{CO}$  show that its electrical structure is  $\text{C}^+\text{C}^+\text{O}$ , whence the central  $\text{CO}_2\text{H}$  in (a) must have the structure  $\text{O}$  and the other two the structure  $\text{O}$ . By similar reasoning

based on the behavior of  $\text{AcCH}_2\text{CO}_2\text{H}$  on hydrolysis and on the addition reactions of  $\text{CH}_2:\text{C}:\text{O}$ , H. and K. arrive at the following electronic formulas for  $\text{AcOH}$ ,  $\text{Me}_2\text{CO}$ ,  $\text{AcCH}_2\text{CO}_2\text{H}$ , (b) and (a), resp.:

CHAS. A. ROULLIER.

**The reaction between acid halides and aldehydes. I.** ROGER ADAMS AND E. H. VOLLWEILER. *J. Am. Chem. Soc.* 40, 1732-46 (1918).—To prep. the following addition compds. equimol. amts. of the aldehyde and acid halide (in the case of  $(\text{COBr})_2$ , 2 mols. aldehyde to 1 of bromide) were allowed to stand in well stoppered flasks until solidification took place; with aliphatic compds. the mixts. must be heated, often under pressure. The ease of formation varies greatly for different compds. and no general conclusions can be drawn as to effect of various groups on the speed of formation; the indications are, however, that negatively substituted compds. react less readily than the unsubstituted ones. The products have the general structure  $\text{RCO}_2\text{CHXR}'$  or  $(\text{CO}_2\text{CHXR})_2$ . Ag salts of org. acids,  $\text{R}'\text{CO}_2\text{Ag}$ , give  $\text{AgX}$  and  $\text{RCO}_2\text{CHR}'\text{O}_2\text{CR}'$ .  $\text{H}_2\text{O}$  gives the aldehyde, org. acid and halogen acid, the difference in the rate of decompn. of different compds. being very marked. Alc. gives the aldehyde, organic acid ester and halogen acid. Dry  $\text{NH}_3$  in  $\text{Et}_2\text{O}$  yields the aldehyde, org. acid amide and  $\text{NH}_4$  halide, while  $\text{PhNH}_2$  in dry  $\text{Et}_2\text{O}$  reacts quant. according to the equation  $\text{RCO}_2\text{CHXR}' + \text{PhNH}_2 = \text{RCO}_2\text{H} + \text{PhNHCHXR}'$ . The following *benzoyl bromide addition products* are described: *o*-bromobenzaldehyde (yield, quant. in 7 hrs.), crystals from ligroin, m.  $106-7^\circ$ ; *p*-bromobenzaldehyde (quant. yield in 3 hrs.), m.  $110^\circ$ ; nitroanisaldehyde (yield, quant. in 3 hrs.), m.  $101-2^\circ$ ; acetovanillin (yield, 75% in a few hrs.), m.  $102-3^\circ$ ; *p*-nitrobenzaldehyde (small yield in 1 day), m.  $89-90^\circ$ ; bromopiperonal, m.  $108-13^\circ$ ; terephthalaldehyde,  $\text{C}_{10}\text{H}_8\text{O}_4\text{Br}_2$ , crystals from  $(\text{CH}_2\text{Cl})_2$ , m.  $153-62^\circ$ ; piperonal (small

yield after several days), m.  $105-10^{\circ}$ , at once decomps. in air; *methyl salicylaldehyde*, m. about  $50^{\circ}$  but decomps. in the air in 10 sec.; *methylvanillin*, m.  $100^{\circ}$ , decomps. in a few sec. *Benzoyl chloride addition compounds*: *bromomethylvanillin* (after 1 week), m.  $158-60^{\circ}$ ; *bromopiperonal* (after 1 week), m.  $97-102^{\circ}$ . *o-Nitrobenzoyl chloride-benzaldehyde*, in 80% yield after 1 week, m.  $81-2^{\circ}$ ; *m-isomer* (quant. yield after 3 months or, when seeded, after 5-6 days), yellow crystals from ligroin, m.  $87-8^{\circ}$ ; *p-isomer* (quant. yield in 5 days), yellow crystals, m.  $118-8.5^{\circ}$ , stable in air and  $H_2O$  and even for a short time in cold  $Na_2CO_3$ . *Oxalyl bromide addition compounds*: *BzH*, m.  $130-1^{\circ}$ ; *o-bromobenzaldehyde* (quant. yield in 10 hrs.), m.  $140^{\circ}$ ; *cinnamic aldehyde*, m.  $85-6^{\circ}$ ; *anisaldehyde*, m. about  $66^{\circ}$  (decompn.); *nitroanisaldehyde*, m.  $116-8^{\circ}$ ; *m-nitrobenzaldehyde* yellow crystals, m.  $128-9^{\circ}$ ; *piperonal*, m.  $81-3^{\circ}$ ; *vanillin* (yield, 90% after 10 min. in  $Et_2O$ ), m.  $93-5^{\circ}$ ; *acetovanillin*, m.  $142-3^{\circ}$  (decompn.); *furfural*, m.  $76-7^{\circ}$ . *Benzalidene acetate benzoate*,  $PhCH(OAc)OBz$ , from the  $BzBr-BzH$  addition compd. and  $AgOAc$  in  $Et_2O$ , m.  $71-2^{\circ}$ . *Benzalidene benzoate p-nitrobenzoate*, from the  $BzH-O_2NC_6H_4COCl$  compd. and  $BzOAg$ , yellow crystals from  $Et_2O$ -petr. ether, m.  $65-7^{\circ}$ . *Benzylidene-o-toluidine*, from the  $BzBr-BzH$  compd. and  $o-MeC_6H_4NH_2$ , m.  $210-2^{\circ}$ . C. A. R.

The industrial preparation of lactic acid from sugar beets. A. BONELLI AND G. GULINELLI. *Ind. chim. min. met.* 5, 121-4 (1918).—Raw beet juice has proved to be a very satisfactory material from which to prep. lactic acid in Italy. The juice is fermented in acid-proof vats, air being blown in and powdered lime added from time to time in such quantity as to maintain an acidity equiv. to 5-7 g.  $H_2SO_4$ . The fermented juice is pumped through heating coils into a "defecator," where it is treated with 1.5-2.5%  $CaO$ . Excess lime is pptd. by  $CO_2$ . After filterpressing the soln. is concd. in multiple-effect evaporators to  $32-4^{\circ}$  B $\acute{e}$ . The hot liquor is acidified with  $50-3^{\circ}$  B $\acute{e}$ .  $H_2SO_4$  in water a cooled tank, cooled and centrifuged. The liquor is then treated with  $Ca_2Fe(CN)_6$  to remove iron, neutralized with lime, and filter-pressed, giving a product containing 40-5% lactic acid. J. S. LAIRD.

Arsenotungstic and arsenotungstomolybdic complexes as reagents of phenolic amines (GUGLIAMELLI) 7. Crystallography and optical properties of three aldopentoses (WHERRY) 2. Artificial coloration of spherulites with helicoidal development (GAUBERT) 2. Nitrating organic compounds (U. S. pat. 1,283,617) 24. Mixed ketones for use as solvents (U. S. pat. 1,283,183) 23. Diolefins (U. S. pat. 1,282,906) 22.

Acetic anhydride. H. DREYFUS. U. S. 1,283,115, Oct. 29.  $Ac_2O$  is made by reaction of a mixt. of  $H_2SO_4$  with 50-70% free  $SO_3$  upon  $NaOAc$  or other acetate in dry form, at a temp. maintained below  $-5^{\circ}$ , in the presence of liquid  $Ac_2O$ .

Oxidizing side chains of aromatic hydrocarbons. H. D. GIBBS. U. S. 1,284,887, Nov. 12. In oxidizing the side chain of an aromatic hydrocarbon, e. g., in making *benzaldehyde* and *benzoic acid*, from toluene, a mixt. of the vaporized hydrocarbon with air passed over a catalyst consisting of oxides of V at a temp. of  $200-400^{\circ}$ . Oxides of Al, Sb, Bi, Ce, Cr, Ag, Co, Mg, Mo, Sn, Ti, W, V and Zn also may be used.

Phthalic anhydride, phthalic acid, benzoic acid and naphthoquinones by the oxidation of naphthalene. H. D. GIBBS and C. CONOVER. U. S. 1,284,888, Nov. 12. Oxidation of  $C_{10}H_8$  is effected by passing a mixt. of  $C_{10}H_8$  vapor and air over Mo, oxides heated to 350–550° (preferably 500°).

Alcohols, esters. DU PONT DE NEMOURS & Co. Brit., 119,249, June 9, 1917. Alcs. are prepd. by reacting with a halogen hydrocarbon on a salt of a higher fatty acid, e. g., Na stearate, and saponifying the resulting ester. A suitable app. is specified. The reaction vessel, e. g., is half filled with stearic acid, the equiv. of solid NaOH is added, the mixt. is heated by an oil jacket to 200–40°, and a mixt. of pentyl and hexyl chlorides is run in from a suitable vessel. Unchanged chlorides, and olefins produced as by-products, distil over to condenser and receptacle. The reaction vessel is then cooled to 150°, NaOH is added, and the vessel again heated to saponify the esters. The resulting alcs. are distd. off in steam, and the process is repeated until the stearate in the reaction vessel has become highly charged with salt. Then the mixt. is removed, acidified, warmed, and the stearic acid decanted off, and washed for re-use. In a modified construction of app., a reflux condenser is provided to return unchanged chlorides to the reaction vessel, while only the olefins pass off to the condenser.

Ethyl alcohol from acetaldehyde. T. LICHTENHAHN. Can. 187,609, Nov. 26, 1918. EtOH is prepd. from AcH by reduction with H in the presence of a catalyst, the H used being in such large excess that the heat of reaction of nearly 300 calories per kg. of EtOH produced is carried away by the H, so as to maintain a const. temp. favorable for smooth reaction without decomposing the AcH.

Salicylic acid from *o*-cresol. H. TERRISSE. Swiss 78,105, June 17, 1918. *o*-Cresol is fused with a caustic alkali in the presence of an alkali metal and an oxidizing agent.

Benzoylating amino organic compounds. F. REVERDIN. Swiss 76,558, June 17, 1918. In the benzoylation of amino derivs. of organic substances by acting thereupon with BzCl, a small amt. of concd.  $H_2SO_4$  is added to the amino deriv. and the BzCl, and the reaction is effected at a moderate temp. and without employing a solvent.

Alkylating agents. E. J. BOAKE and T. H. DURRANS. Brit. 119,250, June 20, 1917.  $Me_2SO_4$ ,  $MeHSO_4$ , and MeCl are prepd. by treating MeOH (2 mols.) with  $SO_2$  (1 mol.) and Cl (1 mol.). The two gases are passed, simultaneously or successively, into the alc.; MeCl is evolved; the reaction product is heated to drive off dissolved MeCl, and is then distd. under reduced pressure; the  $MeHSO_4$  is thus converted into  $Me_2SO_4$ , which distils off with that formed in the primary reaction. The MeCl may be freed from HCl and excess of  $SO_2$  by NaOH soln. or slaked lime, and may be liquefied by cold or pressure.

Apparatus for making sodium salicylate by the "Bayer" process. J. D. SARTAKOFF. U. S. 1,284,468, Nov. 12. Drums are provided in which  $PhONa$  soln. is evapd. and treated with  $CO_2$  and the increase in temp. within the drums is regulated automatically.

FRANK P. UNDERHILL.

Retardation by sugars of diffusion of acids in gels. EVARTS A. GRAHAM AND HELEN TREDWAY GRAHAM. *J. Am. Chem. Soc.* 40, 1900–17(1918).—This work was undertaken to find out, if possible, whether the protective action of carbohydrates

against certain toxic agents in the body can be paralleled outside of the body, and the data obtained on the diffusion of electrolytes in gels are discussed in the present paper from the chem. point of view. Into 14-5 mm. tubes at 26° containing 20 cc. of 10% gelatin gels plus a few drops of lysol, enough litmus to give a decided color (and neutralized with 0.2 N NaOH) and the different sugars (glucose, saccharose, lactose) in 0.025 to 0.5 M concn., were carefully introduced 15 cc. of 0.2 N solns. of the acids (HCl, HNO<sub>3</sub>, H<sub>2</sub>SO<sub>4</sub>, H<sub>3</sub>PO<sub>4</sub>, lactic, HCO<sub>2</sub>H, AcOH, PrCO<sub>2</sub>H), and the velocity of the downward diffusion of the H ion was detd. at definite intervals during 144 hrs. by measuring the position of the line of division between the acid and neutral shades of the litmus. The results are reproduced in tables and curves. It was found that the diffusion of the H ion is markedly retarded by the presence of sugars. In agreement with the diffusion law the ratio of the distance of diffusion to the square root of the time was in general found to be constant in the gelatin with or without sugar. The decrease in this ratio with increasing sugar concns. is not proportional to the concn. of the sugar but is relatively greater for the smaller concns.; the exptl. ratio can be approximately represented by the equation  $(\Delta/K_0)^* = ac$ , where  $\Delta/K_0$  is the relative retardation,  $a$  and  $n$  are constants and  $c$  is the concn. of the sugar. NaCl in the gelatin also retards the diffusion of acids but to a less extent than sugar in equal concn. The mechanism of the retardation is briefly discussed.

C. A. R.

#### Salivary amylase. I. A preliminary experimental study of its stability in saliva.

ROLLIN C. MYERS AND LEONARD C. SCOTT. *J. Am. Chem. Soc.* 40, 1713-6(1918).—Salivary amylase in sterilized saliva without preservative is relatively stable for 1 year, this relative stability varying from practically no change to a decrease of over 50% in amylolytic activity, the variation depending probably on slight differences in compn. of the saliva. The causes which lower the stability of salivary amylase in saliva are not solely the degrading action of bacteria, mold spores, yeast plants and special preservatives; the inherent chem. weakness of the enzyme mol., rather, must be taken into account; this weakness may be increased by temps. of 18° to 30°, diffused light and compds. in saliva. Salivary amylase in saliva is relatively stable for a year in the presence of toluene, CHCl<sub>3</sub>, or thymol; toluene has the least destructive action and thymol and CHCl<sub>3</sub> follow in the order given. Saliva may be kept for 2.5 years under ordinary laboratory conditions without preservative and still show a form of amylolytic activity.

C. A. ROULLER.

The chemotaxis of bacteria against optically active amino acids. H. PRINGSHEIM AND G. ERNST. *Z. physiol. Chem.* 97, 176-90; *Physiol. Abstracts* 3, 298-9.—Amino acids, extd. from org. tissues, and those obtained synthetically were compared in regard to their chemotactic effect on bacteria. The threshold of excitation in the case of synthetically obtained amino acids was found to be 100-1000 times higher than for natural amino acids even when the substances in the 2 cases were optically isomeric.

C. J. WEST.

Compounds derived from proteins by energetic treatment with nitric acid. F. KNOPP. *Z. physiol. Chem.* 101, 210-1(1918); *J. Chem. Soc.* 114, I, 412.—The unidentified acid substances discovered by Mörner among the oxidation products of proteins are probably 5-nitroglyoxaline-4-carboxylic acid, C<sub>8</sub>H<sub>5</sub>O<sub>4</sub>N<sub>3</sub>, and glyoxaline-4-glyoxylic acid, C<sub>8</sub>H<sub>4</sub>O<sub>6</sub>N<sub>2</sub>. Both substances are oxidation derivs. of histidine and have the properties described by Mörner. Attention is directed to the fact that the latter substance must contain either 2 or 4 atoms of H instead of 3 (as found by Mörner) if it consists of a simple mol.

C. J. WEST.

Action of aldehydes upon urease. M. JACOBY. *Biochem. Z.* 85, 358-64(1918); *Physiol. Abstracts* 3, 224.—AcH hinders the action of urease as is already known. AcH.HCN augments its activity.

C. J. WEST.

Mutual action of calcium and magnesium salts on their diffusion through colloids (TADOKORO) 2. Proteinogenous amines (KOESSLER, HANKE) 10. Constitution of the true nucleic acids (FEULGEN) 10. Sitosterol (WINDAUS, RAHLEN) 10.

### B. METHODS AND APPARATUS.

STANLEY R. BENEDICT.

Experiments on the production of antipoliomyelitis serum in rabbits. E. T. H. TSEN. New York. *J. Immunology* 3, 213-7(1918).—Rabbits could not be immunized with poliomyelitis virus to produce serum which could neutralize the effect of the virus.

GEO. T. CALDWELL.

Tables for use in blood analysis. FLORENCE HULTON-FRANKEL. New York. *J. Lab. Clin. Med.* 3, 548-52(1918).—In order to lessen the amt. of calculation necessary in hospital labs. where routine exams. are made, a series of tables were prepd. whereby the results of blood analysis can be read directly, when certain standard methods are used for detn. of non-protein N creatine, sugar, urea or uric acid.

G. T. C.

A simple mounting for the carbon dioxide apparatus of Van Slyke. W. MORSE AND L. L. LANDENBERGER. Chicago. *J. Lab. Clin. Med.* 3, 557-8(1918).—The 50 cc. bulb of the apparatus sits in a clamp which has four jaws generously supplied with thick-walled rubber tubing and the bulb is held in place by means of a hook operated by a special spring at its base, which draws the hook into firm contact with the bulb. The leveling bulb is supported by an ordinary ring fastened to the same ring stand which is used to hold the apparatus proper. From the sides of the ring, 2 in. of metal are cut away for the purpose of admitting the leveling bulb. The method is applicable likewise to the micro-apparatus.

GEO. T. CALDWELL.

*Meningococcus agglutinating serum.* A method of increasing the yield from the rabbit. A. S. G. BELL AND MISS I. M. HARMER. *Lancet* 1918, I, 705-6.—By means of intermittent bleeding a 1500 g. rabbit gave 125 cc. of highly specific serum of a titer of 1:1200, as much as 20 cc. of blood being removed at a single bleeding.

GEO. T. CALDWELL.

Titration of free hydrochloric acid in stomach contents in the presence of dissociated organic acids by means of the addition of alcohol. G. KELLING. *Berl. klin. Wochschr.* 50, 334-6(1918); *Physiol. Abstracts* 3, 380.—The method gives good results.

JULIAN H. LEWIS.

The estimation of nitrogen in the urine by the Kjeldahl method. C. AND M. DEHME. *Berl. klin. Wochschr.* 55, 401-2(1918); *Physiol. Abstracts* 3, 385.—In the present shortage of chemicals the micro-method is urged.

JULIAN H. LEWIS.

Studies in preservatives of biological products. The effects of certain substances on organisms found in biological products. M. H. NEILL. Washington, D. C. U. S. P. H. S., Hyg. Lab., *Bull.* 122, 37-46(1918).—When certain organisms, occurring as contamination of biol. products, were exposed to dilns. of phenol 1:110 and to a soln. of formaldehyde 1:50, a decided variation in the resistance of the organisms was noted. The resistance of the organisms differed both with the disinfectant used and in relation to each other and also as compared with typhoid bacilli. A method of testing the practical value of a substance for the destruction of such chance contaminating bacteria is presented. Trikresol and formaldehyde, when used in amts. usually recommended and tested in serum or broth, were inefficient germicides against certain nonspore-bearing organisms previously isolated from commercial biol. products. Amts. of these substances large enough to have an antiseptic action against some of these organisms used in the test would probably either be deleterious to the

products, or of undue toxicity. These expts. emphasize the necessity for scrupulous care in the prepn. and handling of biological products and demonstrate the fact that the use of preservatives does not insure the sterility of the finished products.

JULIAN H. LEWIS.

**Abderhalden's polarimetric method.** ALFREDO SORDELLI. *Anales soc. quim. Argentina* 6, 31-4(1918).—S. used a no. of samples of placenta peptone of varying origin in tests by the Abderhalden method. With the exception of a Grüber placenta peptone the samples gave results comparable with those mentioned as typical by Abderhalden when tested against sera of pregnancy. The polarimetric readings when the samples were tested against normal sera were also comparable with those given by Abderhalden. Polarimetric readings obtained in the case of sera of cancer, tuberculosis and typhus were of the same order of magnitude as those obtained with sera of pregnancy; these readings were in all cases well above the max. mentioned by Abderhalden as possible with an antigen and non-corresponding serum. The Abderhalden method is lacking in specificity in many instances at least and its diagnostic value is to be doubted.

H. S. PAINE.

**Simulation of albuminuria.** ED. JUSTIN-MUELLER. *J. pharm. chim.* 18, 201-4 (1918).—The use of Maurel's reagent, modified by increasing the 3%  $\text{CuSO}_4$  soln. to 10%, is recommended. Upon mixing the white of  $\sim$  eggs with 1 l. of non-albuminous urine, the times required for the appearance of a white ring were observed when the following reagents were added: Glacial  $\text{AcOH}$ ; the same satd. with  $\text{NaCl}$ ; glacial  $\text{AcOH}$  35 cc., plus 33%  $\text{NaOH}$  15 cc.; Maurel's reagent (33%  $\text{NaOH}$  25 cc., 3%  $\text{CuSO}_4$  5 cc., glacial  $\text{AcOH}$  70 cc.); the reagent modified. The speed of the formation of the ring increased in the ratio of 1 (= 1200 seconds for  $\text{AcOH}$ ):1:8:16:40. S. WALDBOTT.

A new illuminator for microscopes (SILVERMAN) I.

### C. BACTERIOLOGY.

**An improved method of sterilization of infected teeth.** MONTGOMERY LAROCHE. *J. Nat. Dental Assoc.* 5, 1142-4(1918).—A mixt. of equal vols. of distd.  $\text{H}_2\text{O}$  and 95% alc. is satd. with beachwood creosote and  $\text{H}_3\text{BO}_3$ . The resulting soln. is used as an electrolyte with a Pt-Ir electrode in electrolytic medication.

JOSEPH S. HEPBURN.

**Effect of cotton stoppers used in dilution blanks on numerical bacterial count and other practices in the technic of bacteriological laboratories.** ROY S. DEARSTYNE. *J. Dairy Sci.* 1, 512-6(1918).—It appears from the results that about 8% of the organisms adhere to the cotton stopper on shaking the blank. Organisms were found on strands of the cotton. *B. subtilis* did not generally survive sterilization ( $200^\circ$  for 1 hr.) in the center of cotton stoppers. Shaking bottled milk with the original cap up and inverted gave satisfactory agitation for a representative sample. No difference was found in the propagation of bacteria in glass or paper containers.

H. A. L.

**Urinary antiseptics.** The secretion of antiseptic urine following the intravenous administration of an organo-mercury phthalein derivative. EDWIN G. DAVIS, EDWIN C. WHITE AND ROBERT ROSEN. Johns Hopkins Hospital. *J. Urol.* 2, 277-98(1918).—This paper is a discussion of the chemistry, antiseptic properties, toxicity and excretion of chloro-Hg-fluorescein, a synthetic compd. (cf. *C. A.* 12, 954, 2014) formed by the introduction of one atom of Hg into the fluorescein mol. It has the probable formula

It is readily sol. in dil. NaOH or Na<sub>2</sub>CO<sub>3</sub>. After intravenous injection it is excreted by the kidney as rapidly as is phenolsulfonephthalein. The excretion is accompanied by a cleavage in the organism into fluorescein and some form of Hg combination. In either acid or alk. urine (*in vitro*) chloro-Hg-fluorescein will inhibit the development of the colon bacillus or *Staphylococcus aureus* in a diln. at least as great as 1:10,000. It is more efficient in acid than in alk. urine. The intravenous administration of minute doses (5-10 mg.) to rabbit, dog or man will cause the secretion of antiseptic urine. The antiseptis-producing dose is well within the toxic limit. The single lethal dose for rabbit and dog is approx. 20 mg. per g. of body wt. Half this dose may be given daily to dogs without any ill effects. The computed lethal dose for man is about 140 times the antiseptis-producing dose. No clinical value is yet claimed for this drug, although work has been started to det. this.

JULIAN H. LEWIS.

**Urinary antiseptis.** The secretion of antiseptic urine following the intravenous administration of acriflavine and proflavine. Preliminary report. EDWIN G. DAVIS AND EDWIN C. WHITE. Johns Hopkins Hospital. *J. Urol.* 2, 299-308(1918).—Acriflavine and proflavine retain their antiseptic action when dild. in urine, and in this respect differ from many standard antiseptics. Although strongly antiseptic in both acid and alk. urine, these drugs display a relative weakness in inhibiting the colon bacillus in acid urine. They are efficient in very high diln., however, against colon bacillus in alk. urine, and against the staphylococcus in urine of any reaction. When administered by mouth or intravenously to rabbits and dogs, acriflavine and proflavine appear in the urine in less than 1 hr., and continue to be excreted for about 4 hrs. Quant. detns. of the % of excretion have not been made. Following the intravenous administration of 10-mg. doses of acriflavine to rabbits the urine is rendered antiseptic between the 2nd and 4th hrs. The exact time limits have not been detd. Corresponding doses by mouth did not produce antiseptic urine. Following the same dose per kg. to dogs, no antiseptic action in the urine could be demonstrated. This may be due to the acidity of the dog urine, as compared with the alkalinity of the rabbit urine. Rabbits tolerate 25-mg. doses of acriflavine without apparent effect, but do not survive 50-mg. doses (intravenously). No apparent effect upon 10-kg. dogs was observed following 100-mg. and 200-mg. doses given intravenously. Preliminary expts. indicate that acriflavine may prove to be of value for internal use in alk. infections of the urinary tract.

JULIAN H. LEWIS.

**Urinary antiseptis.** The antiseptic properties of normal dog urine. EDWIN G. DAVIS AND R. F. HAIN. Johns Hopkins Hospital. *J. Urol.* 2, 309-20(1918).—Normal dog urine, obtained by aseptic catheterization, shows a distinct antiseptic action, which is particularly marked against organisms of the colon-typhoid group, less effective against *Staphylococcus aureus*, and entirely inert against at least one strain of *Staphylococcus albus*. This antiseptic action is not const. for all dogs, nor for the same dogs on all occasions. It was exhibited, however, by the urine of one dog in 29 out of 30 catheterizations. Dog urine, inoculated with the colon bacillus and incubated, may become sterile during as short a period as 6 hrs. The antiseptic action of dog urine bears no relationship to the H<sup>+</sup> concn., nor is it influenced by the action of various extractives of the urine. Of those specimens of dog urine which act as suitable culture media, some may be rendered unsuitable by passage through a Berkefeld filter.

JULIAN H. LEWIS.

**The effect of ether on tetanus spores and on certain other microorganisms.** H. B. CORBITT. U. S. P. H. S., Hyg. Lab., *Bull.* 112, 47-8(1918).—In order to hasten the reduction in the no. of living bacteria which occurs when ground vaccine virus is exposed to the action of glycerol it has been recommended that the vaccine be treated with Et<sub>2</sub>O vapor. A method more drastic than that recommended is used to test

the action of  $\text{Et}_2\text{O}$  against tetanus spores. Treatment of tetanus spores with  $\text{Et}_2\text{O}$  at  $40^\circ$  for 48 hrs., or intimate mixing of  $\text{Et}_2\text{O}$  and tetanus spores up to 2 wks., failed to kill them. Therefore  $\text{Et}_2\text{O}$  cannot be depended on to kill spores in vaccine virus.

CARL L. ALSBERG.

Present state of the anthocyanin question. J. BEAUVERIE. *Rev. gén. sci.* 29, 572-9(1918). E. J. C.

The dynamics of photosynthesis. W. J. V. OSTERHOUT AND A. R. C. HAAS. *J. Gen. Physiology* 1, 1-16(1918).—See *C. A.* 12, 2597. E. H.

The influence of certain added solids upon the composition and efficiency of Knop's nutrient solution. E. H. TOOLE AND W. E. TOTTINGHAM. *Am. J. Botany* 5, 452-61(1918).—In Knop's nutrient soln. the growth of barley was increased by the addition of  $\text{Fe}(\text{OH})_3$ , was depressed by the addition of carbon black and was unaffected by  $\text{H}_2\text{SiO}_3$ . Root development was unaffected in each case. The total range in acidity of the cultures was comparatively small; the weight of dry tops was inversely proportional to the H-ion concn. of the soln. A large amt. of the P of Knop's soln. was taken out of soln. by the application of a greater amt. of  $\text{Fe}(\text{OH})_3$ . It is stated there was no evidence of poor P nutrition.  $\text{Fe}(\text{OH})_3$  produced neutrality of the nutrient medium, which may have been a factor contributing to the higher yield.

J. J. SKINNER.

The osmotic concentration of the tissue fluids of phanerogamic epiphytes. J. A. HARRIS. *Am. J. Botany* 5, 490-506(1918).—One of a series of papers dealing with the problem of the physio-chem. properties of vegetable saps in relation to environmental factors and geographical distribution. It was found that the osmotic concn. of the tissue fluids of epiphytic Bromeliaceae, Orchidaceae, Piperaceae, and Gesneraceae is far lower than that of terrestrial vegetation. In the Jamaican montane rain forest where direct comparisons for individual habitats are possible, the epiphytes show from 37 to 60% of the concn. characteristics of herbaceous terrestrial vegetation, and from 28 to 40% of the concn. of ligneous terrestrial vegetation. In the Bromeliaceae, Orchidaceae, and Peperomia of the Piperaceae, the osmotic concn. of the species of the Jamaican montane rain forest is lower than that of the species of the hummocks of subtropical Florida.

J. J. SKINNER.

Stimulation of root growth in cuttings by treatment with chemical compounds. O. F. CURTIS. Cornell Agr. Expt. Sta., *Memoir* 14, 78-135(1918).—It is shown that  $\text{MnO}_2$ ,  $\text{MnSO}_4$ ,  $\text{Al}_2\text{Cl}_6$ ,  $\text{FeCl}_3$ ,  $\text{FeSO}_4$ ,  $\text{H}_3\text{BO}_3$  and  $\text{P}_2\text{O}_5$  have a slight stimulating effect on the rooting of cuttings. Solns. of the nutrient salts were injurious in most cases to root growth in cuttings. Root growth of *Ligustrum ovalifolium* in solns. was stimulated by  $\text{KMnO}_4$  in concns. varying from 0.5 to 2% when treated for 24 hours in concns. of 0.05 to 0.5% when treated for 5 days and in concns. of 0.0001 to 0.16% with continuous treatment. Immature twigs can be caused to absorb sucrose and store it in such form as to be available as a food supply for increased root development. Mature twigs are but slightly benefited or may even be somewhat injured by treatment with sucrose. Any injury accompanying treatment with sugar is due to resulting products formed by bacterial or fungus action.

J. J. SKINNER.

Hastening the germination of Bermuda grass seed by the sulfuric acid treatment. W. E. BRYANT. *J. Am. Soc. Agron.* 10, 279-8(1918).—Bermuda grass seed were treated with  $\text{H}_2\text{SO}_4$  for periods varying from 5 to 60 min. Lots treated for 10 min. gave the quickest germination; 95% of the total germination was obtained at the end of the 4th day.

## E. NUTRITION.

### NORMAL.

PHILIP B. HAWK.

Is the amount of calcium usually given in dilutions of cow milk injurious to infants? L. E. HOLT, A. M. COURTNEY AND H. L. FALES. Babies Hospital and Rockefeller Institute, New York. *Am. J. Dis. Children* 16, 52-6(1918).—Bosworth, Bowditch and Giblin recommend "decalcified" milk for infants to aid the resorption of fat and to avoid constipation with subsequent "blowup." It is shown that the fat retention of infants fed with simple milk mixtures is very good, indeed better than the fat retention obtained by these authors with their decalcified milk. S. AMBERG.

Is the amount of calcium usually given in dilutions of cow milk injurious to infants? A. W. BOSWORTH, H. I. BOWDITCH AND L. A. GIBLIN. *Am. J. Dis. Children* 16, 265-7(1918).—This paper is a reply to the criticisms of Holt, Courtney and Fales (preceding abstract). S. AMBERG.

## F. PHYSIOLOGY.

ANDREW HUNTER.

Variations in the lipid ("fat") content of the blood of infants under certain nutritional conditions. W. M. MARRIOTT AND W. R. SISSON. *Am. J. Dis. Children* 16, 74-82(1918).—The total lipoids of the blood were detd. by Bloor's nephelometric method. A few normal cases were studied. The greater number of the infants was suffering from more or less severe nutritional disorders. The cases were grouped according to their nutritional state. Seven, weighing 85-100% of av. normal wt., showed 0.57-0.81% fat in the blood, with an av. of 0.68%; 7, with 70-85% of normal wt., had 0.52-0.83% (av. 0.66%); 13, weighing 60-70% of the normal, had 0.5-1.0% (av. 0.69%); 25, weighing below 60% of the normal, had 0.52-0.96% (av. 0.68%). The fat content of the blood, therefore, is independent of the state of nutrition of the infant. Thirteen cases gaining in wt. had 0.64-1.0% fat in the blood, av. 0.76%. Of these 5 were breast-fed, giving 0.77-1.0%, av. 0.82; 8 were artificially fed, giving 0.64-0.84%, av. 0.72. In 14 cases with stationary wt. was found 0.5-0.76%, av. 0.64. In 25 cases losing wt. the figures were: 0.52-0.96, av. 0.66%. Eight infants on a fat-free diet had 0.52-0.7%, av. 0.63%. In 10 cases the blood was taken during starvation, and contained 0.52-1.02% fat, av. 0.75%. In 5 cases with acidosis (not due to acetone "bodies") the figures were 0.67-0.83, av. 0.74%. S. AMBERG.

Normal isohemagglutinins: their occurrence in human blood and their relation to blood transfusion. S. W. SAPPINGTON AND JAMES S. SEITZ. Hahnemann Medical Coll., Phila. *Hahnemannian Monthly* 53, 536-45(1918).—These workers adopt for human blood the following classification which has been used by some but not all previous investigators. *Group 1*: Its serum agglutinates corpuscles of groups 2, 3 and 4; its corpuscles are not agglutinated by any sera. *Group 2*: Its serum agglutinates corpuscles of groups 3 and 4; its corpuscles are agglutinated by sera of groups 1 and 3. *Group 3*: Its serum agglutinates corpuscles of groups 2 and 4; its corpuscles are agglutinated by sera of groups 1 and 2. *Group 4*: Its serum does not agglutinate any corpuscles; its corpuscles are agglutinated by sera of groups 1, 2, and 3. Study of the blood of 163 medical students showed the relative frequency of the groups to be: group 1 39.3%, group 2 42.9%, group 3 12.9%, group 4 4.9%. J. S. HEPBURN. J

**A gradient of metabolism in the intestinal muscle.** W. C. ALVAREZ. *Proc. Am. Physiol. Soc., Am. J. Physiol.* 45, 579(1918).—Gradients in rhythmicity, irritability and latent period are best explained by the presence of an underlying gradient of metabolism. "Child has shown that the regions of high rates of metabolism and faster oxidation suffer more from the action of weak solns. of KCN than do the regions of slower rates." The action of KCN soln. (1 to 1,300,000) on five segments from different parts of the intestine, caused a marked loss of tone and rhythmicity in the duodenum and jejunum, while the ileum and colon are much less affected. "Some 75 drugs have been tried out and several show similar differences in their action on different parts of the gut." It is concluded that these observations, together with those of Child, furnish proof of the presence of a metabolic gradient down the intestine. It is suggested that some of the emetics and purgatives owe their effects to alterations in this gradient.

G. MCGUIRE.

## G. PATHOLOGY.

H. GIDEON WELLS AND ANDREW HUNTER.

**The curative and prophylactic value of vaccines in pertussis.** L. H. BARENBERG. *Am. J. Dis. Children* 16, 23-9(1918).—Pertussis vaccine even in large dosages did not have any curative effect. It has some prophylactic potency.

S. AMBERG.

**Further report on the use of pertussis vaccine controlled by the complement fixation test.** E. J. HUENKENS. Univ. Minn. *Am. J. Dis. Children* 16, 30-3(1918).—Only fresh pertussis vaccine (that is, vaccine less than 1 week old) without preservative should be used. Such vaccine when given in large doses leads to demonstrable antibody formation. It is most effective as a prophylactic.

S. AMBERG.

**A protective therapy for varicella and a consideration of its pathogenesis.** A. F. HESS AND L. J. UNGER. *Am. J. Dis. Children* 16, 34-8(1918).—It is possible to bring about immunity to chicken pox by means of an intravenous injection of the contents of the vesicles.

S. AMBERG.

**Active immunization of infants against diphtheria.** A. B. ZINGHER. New York City Dept. of Health. *Am. J. Dis. Children* 16, 83-102(1918); cf. *C. A.* 12, 161.—All infants below 12 and if possible below 18 months of age should be actively immunized with three doses, each 1.0 cc., of toxin-antitoxin. These injections should be given irrespective of the Schick test the infants may show at the time of immunization. The injections are given subcutaneously one week apart. The mixt. should be slightly toxic and should represent about 85% of an L + to each unit of antitoxin.

S. A.

**The effect of injections of pituitary solutions on the urinary output in a case of diabetes insipidus.** S. W. CLAUSEN. Washington Univ., St. Louis. *Am. J. Dis. Children* 16, 195-204(1918).—The observations were made on a boy 9 1/2 years of age. Subcutaneous injections of pituitrin diminish the output of urine markedly. The hourly rate of Cl elimination is always reduced after the injections, that of urea only slightly, if at all. The hourly excretion of creatinine, uric acid and titratable acids is only slightly reduced. When the hourly ingestion of water and NaCl or urea is maintained at a const. high level, the elimination of urea is uninfluenced by the injection of pituitary soln., whereas the Cl elimination is considerably, and the water elimination very much, diminished.

S. AMBERG.

**The normal agglutinins for different kinds of pathogenic bacteria in the serum of cold-blooded animals.** M. TAKENOCHI. Univ. Chicago. *J. Infect. Dis.* 23, 393-5(1918).—The normal serums of various species of turtles show fairly high agglutinating values for certain bacteria which are pathogenic for warm-blooded animals and do not grow readily at the body temp. of cold-blooded animals. These facts are theoretically interesting, because, according to the prevalent hypothesis, the occurrence of normal agglutinins is due to a slight unrecognized infection or to the absorption of some sp.

toxic substance from the intestinal canal during life. This seems improbable, especially in the case of cold-blooded animals. JULIAN H. LEWIS.

**Cytolytic action of normal and immune serum on infusoria.** M. TAKENOUCHI. Univ. Chicago. *J. Infect. Dis.* 23, 396-414(1918).—The serums of man, horse, sheep, hog, beef, guinea pig, rabbit, pigeon, frog and turtle were tested to det. the smallest amt. which is necessary to kill the same no. of infusoria (*Paramecium caudatum*). Dilns. were made with 0.6% NaCl. The toxic action of serum consists in depression of motility, discharge of trichocysts, swelling and finally disintegration of the bodies of paramecia. Colpoda is somewhat more resistant than Paramecium. The acting substance or substances can be adsorbed by various adsorbents. The toxic activity disappears when serum is heated at 56° for about 1½ hr. (warm-blooded animals) or at 53° for 20 min. (cold-blooded animals). The reactivation was tested with fresh normal guinea-pig serum as complement source. Fresh guinea-pig serum contains relatively more complement than is required to combine with its own amboceptor. A phenomenon similar to the so-called "complement deviation" was observed. Evidently the action of serum on paramecia is analogous to bacteriolysis and hemolysis. Inactive serum of cold-blooded animals (frog and turtle), however, cannot be complemented by the normal complement either of guinea pig or of frog serum. Immune rabbit serums contain about 10-15 times as much amboceptor as the normal rabbit serum. The normal serums of cold-blooded animals have a very much stronger activity than the serum of warm-blooded animals. The morphol. and physiol. alterations of paramecia observed under the influence of normal and immune serums lead the authors to conclude that the action of serum on infusoria is typically serologic—a beautiful example of the mechanism and nature of cytotoxicity. JULIAN H. LEWIS.

**Lysis and agglutination of red corpuscles of warm-blooded animals by the normal serum of cold-blooded animals.** M. TAKENOUCHI. Univ. Chicago. *J. Infect. Dis.* 23, 514-25(1918).—The normal serums of different species of turtle contain different amts. of lysins and agglutinins for different kinds of corpuscles of warm-blooded animals. The normal serum of turtle (*Chrysemys picta*) contains several lysins and agglutinins for erythrocytes of warm-blooded animals. The normal lysins of the turtle serum lyses the red corpuscles of warm-blooded animals even at 0°. The red corpuscles of rabbit blood hardened by Hayem's soln. cannot be lysed by the turtle serum, unless the fixation is incomplete. For the agglutination of hardened corpuscles a certain amt. of electrolyte is necessary. Reactivation of inactive turtle serum by normal complement of guinea pig or frog was tested with negative results. The agglutinins of turtle serum for erythrocytes of warm-blooded animals have varying degrees of heat lability. Red corpuscles of some species of the tested animals can absorb agglutinins and lysins for erythrocytes of other animals. The specificity of normal agglutinins and lysins in turtle serum for erythrocytes of warm-blooded animals seems not to be so strict as claimed by Noguchi in the serum of *Limulus polyphemus* and *Musterus canis* for erythrocytes of different cold-blooded animals. However, the serum of turtle seems to contain not only a multiplicity of agglutinins, but also a multiplicity of lysins for red corpuscles of warm-blooded animals. JULIAN H. LEWIS.

**Studies on the biochemistry and chemotherapy of tuberculosis.** XVIII. The use of gold salts in treatment of experimental tuberculosis in guinea pigs. LYDIA M. DEWITT. Chicago. *J. Infect. Dis.* 23, 426-37(1918).—Gold salts, which are highly bactericidal for tubercle bacilli *in vitro*, are not efficacious in the treatment of exptl. tuberculosis in guinea pigs. Chem. analyses of the organs of the animals receiving Au over long periods of time demonstrate that there is no sp. affinity of Au for tuberculous tissues and that the Au in the tissues is probably fixed in the tissue cells in such a form that it cannot inhibit the growth of the tubercle bacillus nor the development of the

tubercle, even when its concn. in the tissues is more than sufficient to cause complete inhibition in the test-tubes.

JULIAN H. LEWIS.

**Liberation of antibodies on injection of foreign proteins.** SIEGFRIED F. HERRMANN. Univ. Minn., Minneapolis. *J. Infect. Dis.* 23, 457-69(1918).—In rabbits sensitized with streptococci a definite liberation of sp. opsonins and agglutinins follows the injection of foreign protein. A similar rise in sp. opsonins also occurs in rabbits sensitized with meningococci. Foreign protein injections have no effect on antibodies in typhoid immune rabbits. In suitable rabbits, which do not readily produce lysins against sheep corpuscles, the injection of foreign protein within 10 days after the injection of antigen is followed by a marked liberation of specific lysins. A variety of foreign proteins can be used. Human serum, typhoid vaccine, human ascitic fluid, and guinea pig serum proved equally efficacious.

JULIAN H. LEWIS.

**The complement fixation test for syphilis (modified Wassermann).** M. H. NEILL. U. S. P. H. S. *Public Health Report Reprint* No. 483.—Coming from the Government laboratories as this does, the article constitutes a long desired source of a standard description of the technic of the Wassermann reaction. It describes in detail the app., the prepn. and testing of the reagents used, and the method of performing the test itself.

JULIAN H. LEWIS.

**Ohmmeter for measuring the electrical resistance of blood. Clinical applications.** CHARLES RICHET, P. BRODIN, G. NOIZET AND F. SAINT-GIRONS. *Compt. rend.* 167, 415-8(1918).—The resistance of blood in a rather large capillary tube was measured by the method of Kohlrausch. Blood from six normal persons gave results ranging from 180 to 228, average 200, cm.-ohms. Seven diseased persons with blood deficient in hemoglobin and of varying density gave resistance figures from 106 to 168 cm.-ohms. The hemoglobin content, density and elec. resistance vary directly. The figures for 8 normal dogs ranged from 175 to 225, average 190. Blood of a nearly starved dog gave 134, which after two days of liberal feeding rose to 146 and in four days to 159 cm.-ohms. In dogs subjected to profuse bleeding the elec. resistance was lowered; the total average of three dogs on the 6th, 7th, 9th, 12th and 20th days after bleeding was 121 cm.-ohms. The elec. resistance of blood furnishes a rapid accurate method which may be substituted for counting erythrocytes.

L. W. RIGGS.

**Elimination of iron and its distribution in the liver and spleen in experimental anemia.** IL. H. DUBIN AND R. M. PEARCE. *J. Exp. Med.* 27, 479-85; *Physiol. Abstracts* 3, 246; cf. *C. A.* 11, 1684.—A chronic exptl. anemia produced in dogs by infecting them with *Trypanosoma equiperdum* was studied. No increased elimination of Fe was observed, whereas storage occurred in the liver and spleen. These results are similar to those found in the study of transient exptl. anemia. The expt. therefore failed to reproduce the changes of Fe metabolism seen in certain of the chronic hemolytic anemias of man. The Fe content of the urine was unchanged after a bile duct-ureter anastomosis had been made. Such animals also showed storage of Fe in the spleen.

C. J. WEST.

## H. PHARMACOLOGY.

ALFRED N. RICHARDS.

**A note on the treatment of malaria by disodo-luargol.** W. A. MURRAY AND R. W. H. ROW. *Lancet* 2, 355(1918).—Disodo-luargol is not a specific for malaria. There are several reasons, both clinical and technical, to render it far less suitable for use than quinine.

GEO. T. CALDWELL.

**Procaine for dental operations.** STEPHEN P. MALLETT. *Dental Cosmos* 60, 966-72(1918).—A discussion of the requisite properties of a local anesthetic, and of the manner in which a mixt. of procaine and adrenaline satisfies these requirements.

JOSEPH S. HEPBURN.

**Industrial aniline poisoning in Massachusetts.** THOMAS F. HARRINGTON. Boston. *Bost. Med. and Surg. J.* 179, 497-500(1918).—Pure aniline does not cause poisoning, but the aniline used industrially contains *o*-, *p*-, and *m*-toluidines and xylydine which are poisonous. The most pronounced symptoms of acute aniline poisoning are dyspnea and cyanosis. The blood changes produced are characteristic. It is turbid and brownish, and shows a spectroscopic band that resembles that of methemoglobin.

JULIAN H. LEWIS.

**Acriflavine in the treatment of gonorrhea. An experimental and clinical study.** EDWIN G. DAVIS AND B. E. HARRELL. Johns Hopkins Hospital. *J. Urol.* 2, 257-76 (1918).—Acriflavine was found to possess a high diffusibility, and to be antiseptic in urine in higher diln. than any other diffusible dye studied. For the colon bacillus it is more antiseptic in alk. than in acid urine, while for the *Staphylococcus aureus* it is equally antiseptic in both. Acriflavine will inhibit the development of the gonococcus in a diln. of at least 1:300,000 (has at least 600 times the strength of protargol). An exptl. and clin. study of this drug in the treatment of gonorrhea showed that it will penetrate through the submucosa of the urethra and bladder. It is non-toxic and only slightly irritating to the urethral mucous membrane. The av. duration of a gonorrhea under this treatment is distinctly less than with the usual methods. In an occasional case it seems without effect upon the course of the disease. J. H. LEWIS.

**Phenols as preservative of antipneumococcus serum. A pharmacological study.** CARL VÖGTLIN. Washington, D. C. U. S. P. H. S., Hyg. Lab., *Bull.* No. 112, 5-13 (1918).—The use of large vols. of serum (50-100 cc.), preserved with phenol and trikresol, given intravenously, in the treatment of pneumonia means the introduction into the circulation of as much as 0.5 g. of phenols at a single injection. Studies of the probable toxic effect of this procedure show that the serum is not toxic if the concn. of trikresol or phenol is no more than 0.5%. It is recommended, however, that these injections be made very slowly.

JULIAN H. LEWIS.

**Possibilities of increasing milk and butter-fat production by the administration of drugs.** ANDREW C. McCANDLISH. *J. Dairy Sci.* 1, 475-86(1918).—The various ways in which drugs might influence activity of the udder are discussed. Two sets of expts. were run, using the drugs: alc., castor oil, pituitrin, pilocarpine, physostigmine, aloes, calomel, nux vomica, Epsom salts, and common salt. Tables of results are given. The above drugs used cannot be relied on to induce an increase in the production of milk or % butter fat. Pituitrin and castor oil caused a decrease in the % of butter fat. There was a wide variation in the individual response of cows to the drugs.

LILLIAN OFFUTT.

**Pathology and treatment of trinitrotoluene poisoning, and the action of other poisons which affect fat metabolism.** A. G. R. FOULERTON. *J. Roy. Army Med. Corps* 30, 535-52; *Physiol Abstracts* 3, 337.—T. N. T. is compared with tetrachloroethane,  $\text{CHCl}_3$ , ether, D. N. T. and P.

C. J. WEST.

An institute for coöperative research as an aid to the American drug industry 17.

#### I. ZOÖLOGY.

R. A. GORTNER.

**Evidence of toxic action of ovaries of gar.** C. W. GREENE, *et al.* *Proc. Am. Physiol. Soc., Am. J. Physiol.* 45, 558(1918).—The toxicity of gar ovaries was tested by feeding fresh ovaries to chickens, white rats, cats, and dogs. For chickens "single feed of 5 g. was the minimum toxic dose producing just perceptible symptoms;" if large amts. were fed death was produced in 3 or 4 days. "White rats died after eating quantities as small as 5 g. of gar ovary." Cats and dogs vomited the ovaries within two and a half hours, usually earlier. This is a preliminary paper; organic tests and chemical sepsns. are being carried out.

G. MCGUIRE.

## 12. FOODS.

W. D. BIGELOW, F. F. FITZGERALD.

The composition of the juice of rhubarb stems. BESSON. *Mitt. Lebensm. Hyg.* 9, 231 (1918).—Max. and min. values are given for regular detns. including  $\text{SO}_2$ ,  $\text{P}_2\text{O}_5$ ,  $\text{NH}_3$ , oxalic acid, and tannin on 7 juices. B. advises against over-indulgence of rhubarb because of the oxalic acid content.  
H. A. LEPPER.

Dried vegetables and canned vegetables. BALLAND. *Compt. rend. acad. agr. France* 4, 902-7 (1918).—Dried vegetables were first introduced in the French army in 1852. Analyses are given of the following dried vegetables imported from the United States: red beets (1 sample), carrots (3), cabbage (2), julienne (2), turnips (2), onions (2), potatoes (2), soup mixt. of carrots, celery, cabbage, turnips, onions and potatoes (2). Analyses are also given of a number of canned vegetables and mixts. of vegetables. Tables showing the amts. of  $\text{H}_2\text{O}$  drained from various canned vegetables and the water content of the drained vegetables are presented.  
ALBERT R. MERZ.

Forms of adulteration of roasted whole coffee. G. ISSOGLIO. *Turin. Giorn. farm. chim.* 64, 337-47.—Analysis of different grades of coffee of varying origin showed that the loss of wt. of freshly roasted coffee, when heated at  $100-110^\circ$  for 3 hrs. did not as a rule exceed 1.5%; this loss of wt. in the case of roasted coffee which had been exposed to the air for several days never exceeded 4%. Loss of wt. in excess of 4% is, therefore, indicative of adulteration with  $\text{H}_2\text{O}$ . Expts. in which freshly roasted coffee was treated with 5% solns. of borax and alum, resp., showed that only slightly more  $\text{H}_2\text{O}$  was absorbed by the coffee than in cases where (1) a fine jet of  $\text{H}_2\text{O}$  was sprayed on the coffee in the roaster and (2) the coffee was immersed in  $\text{H}_2\text{O}$ ; the theory that coffee may thus be made to absorb a considerably greater amt. of  $\text{H}_2\text{O}$  than by treatment with  $\text{H}_2\text{O}$  alone is, therefore, incorrect. Treatment of coffee with borax or alum solns. was readily detected by analysis of the ash; the ash of a sample treated with alum soln. contained 5.99%  $\text{SO}_2$  and 1.99% Al, whereas the normal  $\text{SO}_2$  content varied from 3.09 to 4.48%. The use of a borax soln. tends by its antiseptic action to prevent the growth of molds to the attack of which coffee treated with  $\text{H}_2\text{O}$  alone is very susceptible. Coffee adulterated with  $\text{H}_2\text{O}$  differs considerably in organoleptic and strictly physical properties from normal roasted coffee. The practice of coating coffee with substances such as paraffin, vaseline, etc., for the purpose of producing luster and preventing evapn. of  $\text{H}_2\text{O}$  may be detected by the decrease in the consts. of the "fat" or  $\text{Et}_2\text{O}$  ext. Many varnishes used for coating coffee may be easily detected by the fact that they are readily sol. in cold  $\text{H}_2\text{O}$  and impart a color thereto, whereas roasted coffee which has not been so treated does not color cold  $\text{H}_2\text{O}$ . I. reports the analysis of 1 of these varnishes which contained, among other constituents, a mucilaginous substance (probably glue).  
H. S. PAINE.

Coffee. ANON. *Bull. Dept. Agr. Trinidad and Tobago* 17, Pt. 2, 62-5 (1918).—A report upon *Coffea excelsa* covering selection, cultivation, yield and market value. Analysis of 1 sample gave:  $\text{H}_2\text{O}$  8.5, caffeine 1.20, N 2.18, and ash 3.2%.

R. B. DEEMER.

Citric acid content of Trinidad limes. W. G. FREEMAN. *Bull. Dept. Agr. Trinidad and Tobago* 17, Pt. 2, 72-3 (1918).—Analyses of ordinary limes, seedless limes, spineless limes, and lemons, and also an acid seedling pomelo are reported. It appears that the citric acid content is not the only factor to be taken into account, since expts. by G. A. Jones (*West Ind. Bull.* 12, 506 (1912); cf. *C. A.* 6, 2958) indicate that juice of the highest quality will be produced with low rainfall upon a non-retentive soil. However, under dry conditions smaller fruits may result, with a lower juice content,

and thus the citric acid content of the juice of a given number of fruits from a dry or wet locality may be much the same. R. B. DEEMER.

**Summary of talk on lemon by-products.** C. P. WILSON. *Calif. Citrograph* 3, 140(1918).—About 6% of the crop of the members of Exchange By-Products Co. was shipped to factory at Corona last season. During the 1916-17 season the Exchange By-Product Co. used 5120 tons of lemons; produced 180,000 lbs. citric acid and returned \$10.00 per ton to the growers; this is \$4.00 per ton better than in the previous season. The estd. increase in lemon crop for next 6 years is 114%. Lemon oil and citric acid must form the basis for utilization of lemons not used as fresh fruit. W. V. CRUICK.

**Orange vinegar instead of apple.** *Calif. Citrograph* 3, 257(1918).—Vinegar of good quality was made in a number of tests in the Citrus By-Products Lab. of the U. S. Dept. of Agr., Los Angeles. The process recommended is: Press out the juice from crushed whole fruit. Leave it in a barrel or wooden tub at about 85° F. until fermentation is complete (3-5 days). Strain the juice. Place in barrel generator previously acidified with unsterilized vinegar. Plans for a barrel generator are given. When the vinegar is finished remove it from the barrel, bottle and pasteurize. W. V. CRUICK.

**The use of salicylic acid in tomatoes and preserves.** P. CARLES. *Repert. pharm.* 29, 255-7(1918).—A general argument against the use of salicylic acid in tomatoes and preserves is given. LILLIAN OFFUTT.

**The use of salicylic acid in tomatoes and preserves.** E. CRIBUZEL. *Repert. Pharm.* 29, 285-7(1918).—Polemic with Carles (preceding abstract). L. O.

**The peanut.** W. D. KERLE. *Agr. Gaz. N. S. Wales* 29, 429, 471-9(1918).—Analyses of parts of the peanut plant, digestible nutrients, av. digestibility, analysis of peanut hay, and fertilizing constituents in various parts of the plant. A report is given of the suitability of soils in Australia for peanut production, trials of local and imported American varieties, and the future of the industrial side of peanut production. R. B. DEEMER.

**Contributions to the cryoscopy and refractometry of milk.** J. PRITZKER. *Mitt. Lebensm. Hyg.* 9, 235-6(1918).—The rise of the  $n$  accompanying an increase of acidity in milk (cf. C. A. 12, 835) is due to the dissolving of insol. salts (di- and tri- Ca phosphates). A detn. of acidity is advisable with each refraction reading as a definite relation exists between these 2 detns. H. A. LEPPER.

**The refractometric quantitative analysis of lactose in milk.** L. PANCHAUD AND E. AUERBACH. *Mitt. Lebensm. Hyg.* 9, 236-9(1918).—Work already done along this line is discussed. The methods used and tables of results are given. The refractometric and gravimetric results on the lactose in normal fresh and watered milk agree remarkably, but the refractometric results on old milk acidified are too high, due to the formation of lactic acid and the non-pptn. of albuminoid substances. The refractometric results of the lactose in the abnormal milk of sick cows are too high, due to the change in the milk brought about by the pathol. condition. LILLIAN OFFUTT.

**The influence of the method of preparation on the specific gravity and refractive index of milk serum.** N. SCHOORL. *Utrecht. Chem. Weekblad* 15, 1089-96; *Pharm. Weekblad* 55, 1222-9(1918).—The conclusion reached by van der Harst and Koers (C. A. 12, 2388), that only the  $\text{CaCl}_2$  serum is sensitive enough to detect 10% of added  $\text{H}_2\text{O}$ , is erroneous, due to errors in their calcns. Their results are calcd. from the min. differences in sp. gr. and  $n$  observed after adding 5 and 10% of  $\text{H}_2\text{O}$  to 10 samples, and the max. differences observed in several genuine samples. Calcns. from the av. differences are much more reliable, since they eliminate any error due to erratic max.

and min. differences. Careful study shows that the HOAc serum is fully as sensitive as the  $\text{CaCl}_2$  serum. As a rule, as little as 5% of added  $\text{H}_2\text{O}$  can be detected with either; while 10% can be detected with certainty, especially when the normal data and seasonal variations are known for a given dairy. Cf. following abstract.

JULIAN F. SMITH.

**Reply to the criticism of Schoorl.** J. C. VAN DER HARST AND (MISS) C. H. KOERS. Middelburg. *Chem. Weekblad* 15, 1096-7; *Pharm. Weekblad* 55, 1229-30(1918); cf. preceding abstract.—The authors maintain that their method of calcn.; while not in accord with theory, gives results which agree with the facts met with in practice, since irregular variations in sp. gr. and % of milk serum commonly occur. The  $\text{CaCl}_2$  serum is least affected by these abnormalities.

JULIAN F. SMITH.

**New formula for the calculation of added water in milk.** LESLIE J. HARRIS. *Analyst* 43, 345-7(1918).—A formula is derived by which the % of added  $\text{H}_2\text{O}$  is calcd. on the assumption that the original milk before watering contains the minimum of fat (3%) and solids-not-fat (8.5%). If  $X = 10,000 N/[3 N + 8.5 (100 - F)]$  wherein  $X$  = % of milk of the minimum standard,  $N$  = % of solids-not-fat, and  $F$  = fat then  $100 - X$  = % added  $\text{H}_2\text{O}$ . Using av. values for  $N$  and  $F$  in place of minimum will give the probable  $\text{H}_2\text{O}$  addition.

H. A. LEPPER.

**Studies on the uniformity of heating in the final package method of pasteurization.** B. W. HAMMER AND A. J. HAUSER. *J. Dairy Sci.* 1, 462-74(1918).—The importance of uniform heating of milk in the final package method of pasteurization is shown. There is a great variation in the extent of the heating of the different bottles in the same run. This method as used in the Iowa State College Market Milk Room gave only small variations in the bacterial content and creaming ability of different bottles from the same run, although bottles at the surface were slightly lower in bacterial content and creaming ability. The detn. of creaming ability by means of tubes of milk allowed to stand was found to be a simpler and quicker method for detg. uniformity in heating than the detn. of bacterial content.

LILLIAN OFFUTT.

**The comparison of bacteria counts in whole and skim milk, separator and centrifuge cream.** R. W. LAMSON. *J. Dairy Sci.* 1, 498-507(1918).—The results obtained in these expts. indicate that the number of bacteria is less or only slightly more in sepd. cream than in the whole milk from which it is sepd. Centrifuge cream in closed container showed 6-25 times as many bacteria as original milk. Skim milk has less bacteria than whole milk. There is no definite relation between butter fat and % of bacteria found in cream. These results on sepd. cream and centrifuge cream agree with those obtained by other workers. A common bacteriol. standard for market whole milk and cream is desired.

LILLIAN OFFUTT.

**Production of acid phosphate from creamery waste sulfuric acid.** R. H. CARR. *J. Dairy Sci.* 1, 508-11(1918).—The  $\text{H}_2\text{SO}_4$  used in fat testing in dairy plants is of further value in the production of acid phosphate. A good grade of fertilizer can be made from this acid as it carries N and K which enhance the value of the finished product. Analyses of spent acid and fertilizer produced by it are given.

H. A. LEPPER.

**The establishment and management of the dairy farm in India.** R. KELKAR AND G. K. BAHADUR. Dept. Agr. Bombay, *Bull.* 1917, 86, 1-60; *Bull. Agr. Intelligence* 9, 859-62(1918).—Tables concerning the breed of cow or buffalo, number in herd, av. price, av. wt., time under observation and yield per head of milk in lbs. for yr. are given. Analyses of milk and proportion by wt. of butter fat to milk are tabulated. The processes of making butter from buffalo's milk are discussed. The business aspect of the dairy industry is taken up under the headings of equipment, machinery and

other dead stock, management and labor, dairy buildings, scheme for continuous supply of green fodder, recurring annual expenses, recurring expenditure on feed and maintenance of live stock, and record sheets to be kept on dairy farm of 200 head of cattle.

LILLIAN OFFUTT.

The utilization of horse serum in man's diet. L. LINDET. *Compt. rend. acad. agr. France* 4, 807-10(1918).—The possibilities of the use of the albumin of horse blood as a substitute for the albumin of the white of eggs are discussed. Horse blood contains 8% coagulable albumin, the white of eggs 10%. Various dishes prepd. from the serum are mentioned.

ALBERT R. MERZ.

Composition and feeding value of leaf hay. F. HONCAMP AND E. BLANCK. *Landw. Vers. Sta.* 91, 291-308(1918); *J. Soc. Chem. Ind.* 37, 527A.—Dried leaves of the beech, maple, lime, birch, alder, chestnut, etc., form a valuable feeding stuff; they contain 10-23% of protein, 2-10 of fat, and 17-22 of crude fiber.

L. J. GILLESPIE.

Composition and digestibility of heather and reindeer moss. F. HONCAMP AND E. BLANCK. *Landw. Vers. Sta.* 91, 223-51(1918); *J. Soc. Chem. Ind.* 37, 527A.—Heather meal contains about 7% of protein, 9 of fat, 8 of ash, and 12 to 21 of crude fiber; when prepd. from the leaves and flowers only it has about the food value of hay of poor quality. Reindeer moss has 4% of protein and 2 of fat and is of little value as fodder.

L. J. GILLESPIE.

Potato peelings and heather as coarse fodder for horse. Researches in Holland. P. A. VAN DRIEST. *Tydschrift voor Diergeneeskunde*, Pt. 45, No. 10, 286-8; *Bull. Agr. Intelligence* 9, 846.—Chemical analysis of potato peelings is made. The solanine content is found to be lowered by boiling the peelings for 10 to 15 mins. with a little vinegar in the  $H_2O$ . Boiling also reduces the potash content. It is concluded that potato peelings are good coarse feed for horses. Heather was found to have no influence upon increase in wt. when fed to horses.

LILLIAN OFFUTT.

Alfalfa as a sole feed for dairy cattle. F. W. WOLL. *J. Dairy Sci.* 1, 447-61 (1918).—Cattle fed on mixed rations do better than those fed solely on alfalfa in that there was greater increase in wt. and slightly larger body development; the calves dropped by the heifers were uniformly heavier; and there was greater dairy production. Analyses of the mixed rations and alfalfa feed are given. The economical side of feeding alfalfa is discussed. Tables of the feeding expts. are given.

LILLIAN OFFUTT.

The utilization of corozo wastes as cattle food. CHARLES BRIOUX. *Compt. rend. acad. agr. France* 4, 926-30(1918).—The greater part of the nut of the Tagua palm (*Phytelephas macrocarpa*) is composed of "mannane," a substance intermediate between starch and cellulose. This can be transformed to reducing sugars by dil. boiling acids. The total amt. of these obtainable exceeds 70% of the wt. of the corozo. Analyses are given of powdered corozo and the work of Beals and Lindsey (*C. A.* 11, 173) on its digestibility and feeding value is reviewed.

ALBERT R. MERZ.

The utilization of corozo wastes and of feed-meals for cattle. DECHAMBRE, *et al.* *Compt. rend. acad. agr. France* 4, 919-24(1918).—A discussion of the above paper of Brioux by various members of the academy. Corozo wastes come from toy factories. The corozo seed contains up to 45%  $P_2O_5$  in its ash.

ALBERT R. MERZ.

Importance of salt in rations. JACOB JOFFE. *J. Dairy Sci.* 1, 487-97(1918).—The use of salt is discussed from a historical and physiological standpoint. Analyses of Na and K in feed stuffs as found in Bunge's Physiologic and Pathologic Chemistry are given. The work of Babcock is reviewed. The salt used by calves varies with different feeds. Lack of salt causes pathologic conditions and so loss in wt., vitality, and production of milk.

LILLIAN OFFUTT.

The cottonseed industry of India (ANON.) 27. Possibilities of increasing milk and butter-fat production by the administration of drugs (McCANDLISH) 11H. Effect of cotton stoppers used in dilution blanks on numerical count and other practices in bacteriological laboratories (DEARSTYNE) 11C.

**Sterilizing milk.** M. MUSSINO. U. S. 1,284,751, Nov. 12. Milk is sterilized by heating in an open vessel to a temp. (preferably about the b. p.) above that at which a skin would ordinarily form upon the surface, while a rigid seal, *e. g.*, a metal float, is maintained upon the surface of the milk, to prevent formation of the skin.

**Milk preparations.** P. W. TURNER. Brit. 119,430, June 24, 1918. Milk is curdled by an enzyme, such as is yielded by rennet or pepsin, at a temp. of 80–100° F., but as soon as the curd has reached a flocculent, slightly adhesive condition the action is stopped by cooling the substance rapidly to a temp. of about 45° F. The curds are then allowed to settle and the whey is decanted off. The curds may be beaten, whipped, colored, flavored, or sweetened as desired, or made into a substance resembling ice-cream by heating in an ice-cream freezer. The whey may be reduced by evapn. to about  $\frac{1}{4}$  of its original bulk, and mixed with the curds. In any case, the product is kept at a temp. of about 45° F. until required.

**Preserving fruit juices.** H. C. GORE. U. S. 1,284,187, Nov. 5. Juice from apples, oranges, lemons or other fruits is filtered and mixed with absorbent black, filtered again to sep. the juice from the black, mixed with infusorial earth and again filtered to remove residual traces of the black and finally sterilized.

**Bread.** H. A. KOHMAN, C. HOFFMAN and A. E. BLAKE. U. S. 1,282,867, Oct. 29. Flour which is to be used with yeast in making leavened bread is mixed with about 0.06% of  $\text{NH}_4\text{Cl}$  and 0.12% of  $\text{CaSO}_4$  to reduce the quantity of yeast required.

**Bread.** H. A. KOHMAN, C. HOFFMAN and A. E. BLAKE. U. S. 1,282,868, Oct. 29. About 10% of  $\text{CaSO}_4$  is incorporated with flour to be used in making leavened bread and this mixt. may be further mixed with about 80 times its weight of additional flour in making up the bread dough. The  $\text{CaSO}_4$  serves to promote the growth of yeast.  $\text{Ca}(\text{H}_2\text{PO}_4)_2$  may also be used for the same purpose.

**Sterilizing bread.** H. J. LUEDERS. U. S. 1,282,251, Oct. 22. Loaves of bread, immediately before being wrapped, are passed through a sterilizing zone heated to 60–315° to kill molds on the crust.

**Flavoring butter substitutes.** DE BRUYN and J. DE BRUYN. Brit. 119,052, June 21, 1917. A flavoring material for edible oils and fats is obtained by extg. sol. proteins from nuts, leguminous seeds, etc., and inoculating the ext. with lactic bacteria without the addition of sugars, salts, or fats. The protein ext. may be dried and reconstituted by the addition of  $\text{H}_2\text{O}$  before the inoculation.

**Drying edible pastes.** K. GAMMEL. U. S. 1,284,305, Nov. 12. The pat. relates especially to drying of macaroni paste foods in a closed chamber by the action of air currents.

**Method and apparatus for dehydrating vegetable materials.** G. H. BENJAMIN. U. S. 1,284,218, Nov. 12. The app. is especially adapted for drying vegetable substances by the action of air currents.

**Liquid food from soy-beans.** A. B. MOSKES. U. S. 1,281,411, Oct. 15. Disintegrated soy beans are mixed with  $\text{H}_2\text{O}$  to produce a fluid mass which is then allowed to stand until the  $\text{H}_2\text{O}$  has dissolved sol. constituents of the beans. The mixt. is then heated to remove substances of unpleasant odor and, after cooling, the liquid is strained and the residue pressed to obtain additional liquid. The mixed liquids form a liquid food, resembling milk.

**Fodder.** R. KRON. Swiss 76,805, June 17, 1918. In the prepn. of a fodder for cattle, or an adulterant for food, wood material is treated with  $H_2O$  or a weak  $NaCl$  to fill the pores, and it is then heated for several hrs. at  $90-120^\circ$ . The liquor is then drained off, and the material is dried and ground.

#### 14. WATER, SEWAGE AND SANITATION.

EDWARD BARTOW AND W. F. MONFORT.

**Composition of the irrigation waters of Utah.** J. E. GREAVES AND C. T. HIRST. Utah Agr. Exp. Sta., *Bull.* No. 163, 43 pp.(1918).—The sol. salts varied in the various sources of water from 84 to 1250 parts per million. Thirteen contained more than 0.06% sol. salts. The salts in the head waters of most streams studied consist largely of  $CaCO_3$  and  $MgCO_3$ . Analyses of the water from a large number of streams and wells are given. J. J. SKINNER.

**Water on the farm.** VIII. F. B. GUTHRIE. *Agr. Gaz. N. S. Wales* 29, 221-3, 381-6, 551-7(1918).—A continuation of a former article (*C. A.* 12, 2642).  $H_2O$  for human consumption is dealt with. Sources of supply, general characteristics, such as salts present, org. matter, O consumed, and interpretation of analyses and standards are discussed. An analysis of a typical potable  $H_2O$  and of Sydney  $H_2O$  is given. Standard methods of filtration and purification are described. R. B. DREMER.

**Clinical method for the examination of potable waters in the field.** L. C. MAILLARD. *Bull. acad. med.* 79, 198(1918); *Schweiz. Apoth. Ztg.* 56, 374-6(1918).—The advantages of the use of a purely chem. method, especially detn. of  $NaCl$  in the  $H_2O$ , compared with the method of counting colon bacilli, are pointed out. To take into account the natural  $NaCl$  content of a  $H_2O$  supply, its normal amt. should be detd.; any subsequent deviation would render the  $H_2O$  suspect. If time permits, both bacteriol. and chem. methods should be used. S. WALDBOTT.

**Sterilization of water by means of ultraviolet light.** D. VITALI. *Giorn. farm. chim.* 64, 246-8.—V. discusses the principle of sterilization of  $H_2O$  by means of ultraviolet rays from solar radiation and also from a Hg lamp in quartz; he also describes a simple app. by means of which ultraviolet rays from the latter source may be used for sterilization of  $H_2O$  in the home, hospitals, etc. It is recommended that beer, artificial mineral waters, ice, etc., should be produced from  $H_2O$  thus sterilized and that such  $H_2O$  should be used for washing bottles, dishes, etc. H. S. PAINÉ.

RACE, JOSEPH: **Chlorination of Water.** New York: John Wiley & Sons. 158 pp. \$1.50.

**Apparatus for purifying water or sewage.** C. F. WALLACE and M. F. TIERNAN. U. S. 1,283,993, Nov. 5. The material to be purified is treated with  $Cl$ .

**Base-exchanging compounds.** G. RUDORF. Can. 187,428, Nov. 12, 1918. A soln. containing silica and alkali is pptd. by an alk. soln. of alumina, the major portion of the mother liquor is removed and the unwashed ppt. is dried and immersed in water to cause granulation and washing.

**Sewage-sludge.** J. W. PHILLIPS. U. S. 1,284,441, Nov. 12. The solid and semi-solid constituents of sewage are treated with  $H_3PO_4$  in excess of the quantity required to decompose the insol. metallic soaps and carbonates present and the oleaginous substances are then extracted with a solvent. The residue is dried for use as a fertilizer.

**Apparatus for purifying sewage or similar liquids.** W. JONES. U. S. 1,282,587, Oct. 22. The material under treatment is subjected to the action of air or O.

**Fertilizer and other values from sewage sludge.** J. W. PHILLIPS. U. S. 1,284,442, Nov. 12. Solid and semi-solid constituents from sewage sludge are treated with  $H_2PO_4$  in excess of the amt. required to decompose the insol. metal soaps present, the excess free mineral acid is neutralized with phosphate rock to form a composite fertilizer and oleaginous materials are extd. with a solvent such as a light hydrocarbon oil.

**Disinfectant.** A. FRANCK-PHILIPSON. U. S. 1,282,062, Oct. 22. A solidified sol. disinfecting compn. is formed by mixing a tar oil with a fat and boiling with sufficient alkali to neutralize the free acids of the tar oil and saponify or partially saponify the fat. The product forms a stable emulsion with  $H_2O$ . Coconut oil is preferably used, with tar oil and NaOH soln.

## 15. SOILS, FERTILIZERS AND AGRICULTURAL POISONS.

J. J. SKINNER.

**Soil aldehydes.** JOSHUA J. SKINNER. *J. Franklin Inst.* 186, 449-80, 547-84, 723-41(1918); cf. *C. A.* 12, 2102.—Presence of 25 parts of *heliotropine* per million in the nutrient soln. produced a marked reduction in the absorption of  $K_2O$ ,  $P_2O_5$ , and  $NO_3$  by wheat plants. *Formaldehyde* (20 parts per million) in the nutrient soln. greatly reduced growth of wheat plants and their absorption of  $K_2O$ ,  $P_2O_5$ , and  $NO_3$ . *Paraformaldehyde*,  $(HCHO)_8$ , was fully as harmful as  $HCHO$  to wheat; 25 parts per million in the nutrient soln. materially injured growth, and 50 parts per million was extremely harmful; phosphates tended to ameliorate the harmful effect; "although growth was more normal in the mainly phosphatic solns., showing that there was some action by the phosphates which changed the physiol. effect of paraformaldehyde, the absorption of nitrates by plants growing in the presence of this aldehyde was more normal than the absorption of phosphates or of K." Pot studies were made concerning (1) the influence of *salicylic aldehyde* and of *vanillin* upon the growth of plants (wheat and legumes) in various soils, and (2) the action of fertilizers in ameliorating the harmful properties of these aldehydes. Liming completely overcame the harmful action of both aldehydes; phosphates ameliorated and sometimes entirely overcame the injurious action of salicylic aldehyde;  $NaNO_3$  lessened that of vanillin; and Mn salts changed the physiol. action of both aldehydes. The beneficial action of  $CaO$ ,  $NaNO_3$ , and Mn was probably due to their stimulation of oxidation and related processes in the soil, as a result of which the org. compds. were destroyed or so changed, that conditions became favorable for plant growth. Similar studies of various soils were carried out as field expts. in widely different geographical locations. Both salicylic aldehyde and vanillin persisted and were harmful in acid soils which possessed weak oxidizing activities and low crop-producing powers: both aldehydes were destroyed without injuring the crops when the field had a limestone soil with strong biological activities and good crop-producing powers; liming greatly lessened their harmful action and hastened their destruction. Use of acid phosphate partially overcame the evil effects of salicylic aldehyde, use of  $NaNO_3$  those of vanillin. When salicylic aldehyde had been formed by nature in a soil, addition of phosphate fertilizers and sufficient lime to prevent acidity greatly improved conditions for growth. "Unfertile soils, where due to the presence of harmful aldehydes, can be made productive by good drainage and by the use of lime and certain fertilizers." The drainage increases the aeration and the oxidation in the soil. A bibliography of 85 references is appended.

JOSEPH S. HEPBURN.

**Soil acidity methods.** R. E. STEPHENSON. *Soil Science* 6, 33-52(1918).—A study was made of 6 methods of detg. soil acidity. Truog's method, which makes use of a 0.4 *N* Ba(OH)<sub>2</sub> soln. to neutralize the acidity, gave higher lime requirement. Tacke's method, which makes use of CaCO<sub>3</sub> and H<sub>2</sub>O to bring about the neutralization of the soil acidity, is concluded to have the greatest possibilities. From a study of Tacke's method it is concluded that pure H<sub>2</sub>O is a reliable medium for bringing about the reaction between the acid soil and carbonate. The use of Ca or NaCl hastens the reaction only slightly. Concd. solns. of these salts prevent fermentative reactions, the rate of reaction being somewhat depressed by concd. chlorides. Antiseptics are not needed. The time, rate of aeration and vigor of shaking are the most important factors in the Tacke method. Methods which depend upon the liberation of an acid from its salt do not give total acidity and indicate a lime requirement which depends both upon the soil and salt used.  
J. J. SKINNER.

**Further investigations on the nature of the soil-particles.** I. PAUL EHRENBURG AND J. P. VAN ZYL. *Intern. Mitt. Bodenk.* 7, 90(1917); *Biedermanns Zentr.* 47, 98-100(1918).—A continuation of the work of van Z. (*C. A.* 11, 3363) for the purpose of detg. the influence of the prepn. of the soil-sample on the cohesion of the soil-particles and to ascertain to what extent this influence can be recognized in the mechanical analysis of the sample by the sedimentation process. Air-drying was found to increase the cohesion of the very fine particles only and this effect can presumably be made use of in ascertaining the structure of the soil. A change in the time of shaking may effect the coherence of the particles considerably, so that when information is desired as to the firmness of the individual particles shaking should be avoided. When, however, consideration is not given to the coherence of the particles, shaking of the sample is advantageous as it saves time. The addition of NH<sub>3</sub> has the same advantage.  
ALBERT R. MERZ.

**The decomposition of organic matter in soils.** F. G. MERKLE. *J. Am. Soc. Agron.* 10, 281-302(1918).—The decompn. of leguminous and nonleguminous vegetable material in soil was studied by measuring the quantity of CO<sub>2</sub> produced. The rapidity of decompn. of maple and oak leaves and pine needles in the soil was about the same. Pine shaving decomposed very slowly. The legumes which are high in N show a more rapid rate of decay than cereal straws and litters which are low in N. The decompn. of soy-bean vines was influenced by com. fertilizers. NaNO<sub>3</sub> and basic slag increased, while kainite and KCl decreased the rate of decompn.  
J. J. SKINNER.

**Hydrogen-ion concentration. Soil type. Common potato scab.** L. J. GILLESPIE AND L. A. HURST. *Soil Science* 6, 219-36(1918).—The colorimetric and electrometric methods for detg. H-ion concn. in soils are described. The results secured by the 2 methods on a large number of soils agree within the exptl. error. A study of a large number of typical potato soils showed a close correlation between H-ion concn. and occurrence of potato scab. Soils having a H-ion concn. as low as 5.2 as a rule do not produce scabby potatoes, while soils having exponents much higher produce scabby potatoes. The H-ion exponent of 2 soil types are compared. The typical Caribou loam has an exponent of about 4.8, whereas the Washburn loam is generally less intensely acid; the former produce clean potatoes while the latter produce scabby ones. No standard H-ion exponent of soils for max. crop production is given. Many soils having the exponent 5 are successfully cultivated in potatoes and truck crops without liming and it is stated that the exponent 7, which indicates physico-chemical neutrality can hardly be taken in general as "the rational" end-point in lime-requirement tests.  
J. J. SKINNER.

**The content of amorphous silicic acid in soils.** BÉLA VON HORVÁTH. *Intern. Mitt. Bodenk.* 6, 288-9(1916); *Biedermanns Zentr.* 47, 97-8(1918); cf. *C. A.* 11, 1709.

—The method of Piedzicki (*Mitt. landw. Inst. Univ. Leipzig* 2, 1-54(1901)) for the detn. of amorphous  $\text{SiO}_2$ , which depends on the treatment of the soil on the water bath with a 10%  $\text{NaOH}$  soln. for 90 min., is shown to give too high results since 0.29, 1.40, and 55% of the  $\text{SiO}_2$  of quartz, feldspar and  $\text{Na}_2\text{SiO}_3$ , resp., are thus dissolved. The treatment of 5 g. of soil with 100 cc. of a 1%  $\text{Na}_2\text{CO}_3$  soln. at  $100^\circ$  for 15 min. is recommended. The quantities of amorphous  $\text{SiO}_2$  as detd. by this method are very small. The explanation is that alkali carbonates are formed simultaneously with the  $\text{SiO}_2$  in weathering and act upon it, forming  $\text{K}_2\text{SiO}_3$ , which is quickly removed in soln. The unaltered amorphous  $\text{SiO}_2$  is also sol. in  $\text{H}_2\text{O}$  and is similarly removed.

ALBERT R. MERZ.

The solubility of the soil potash in various salt solutions. D. K. TRESSLER. *Soil Science* 6, 237-57(1918).—The amt. of  $\text{K}_2\text{O}$  that dissolved in salt solns. was detd. in 2 silt loams, 2 sandy loams, a fine sandy loam, a humus loam and a clay subsoil. The method consists in allowing the soil to remain in contact with the various salt solns. until the systems come to equil. The solns. are decanted and filtered through a Pasteur-Chamberland filter, and the  $\text{K}_2\text{O}$  is detd. by a colorimetric method.  $\text{CaSO}_4$  in soln. increases the soly. of  $\text{K}_2\text{O}$  in some soils. It is more marked in clay than in silt or sand. The soil  $\text{K}_2\text{O}$  of Dunkirk silt loam is more sol. in solns. of  $\text{CO}_2$  and  $\text{CaCO}_3$  than in solns. of  $\text{H}_2\text{CO}_3$  containing the same amt. of  $\text{CO}_2$ . Na salts are very active in dissolving soil  $\text{K}_2\text{O}$ .  $\text{NaCl}$  and  $\text{Na}_2\text{CO}_3$  being more active than  $\text{NaNO}_3$ .  $\text{NaCl}$  in concns. of 300 p. p. m. dissolved appreciable amts. of  $\text{K}_2\text{O}$ . With higher concns. the sol.  $\text{K}_2\text{O}$  increased with the concn. of the salt soln. A partial review of the literature is given.

J. J. SKINNER.

Note on the plasticity and the "firmness" of clay. OTTO NOLTE. *Intern. Mitt. Bodenk.* 6, 351(1916); *Biedermanns Zentr.* 47, 108-9(1918).—A heavy clay was thoroughly extd. with ether and acetone. On evapn. a yellow mass remained which consisted of S and an unidentified org. substance. Extn. did not diminish the plasticity of the clay and N was unable to verify Böttcher's (*Über die Verflüssigung des Tones durch Alkali*. Dissertation, Dresden, 1908) conclusion that this property is predominantly influenced by the org. content. Attention is called to the necessity of guarding against error in the detn. of org. matter by combustion, as  $\text{SO}_2$  from S and pyrite will be fixed by  $\text{PbO}_2$  or similar suitable substances.

ALBERT R. MERZ.

The tote moor (dead bog) beside the Steinhuder Sea. JOHN. *Mitteilungen des Vereins zur Förderung der Moorkultur im Deutschen Reiche* 35, 360(1917); *Biedermanns Zentr.* 47, 104(1918).—A review of the study on bogs by Carl Birk. The geographical, geological, meteorological and biological relations of the bog are described and the chemistry and physics as well as the technical utilization thereof are discussed. An insight is given into the chem. behavior of individual kinds of peat at different depths and at different points in the horizontal extension of the peat bed. For details reference must be had to the review.

ALBERT R. MERZ.

The partial sterilization of soils. G. TRUFFAUT. *Compt. rend.* 167, 433-6(1918).—The results of pot and large-scale field expts. by T. confirm the conclusions of Russell ("Soil Conditions and Plant Growth," London (1912 and 1917); cf. *C. A.* 6, 3153) and Midge (*C. A.* 11, 2381). Treatment of the soil with  $\text{CS}_2$  increased the yields of cabbage and onions and the plants were free from diseases and the attacks of insects.  $\text{CaS}$  similarly increased the yields of various plants.  $\text{CaS}$ , containing 10%  $\text{ZnS}$ , gave diminished yields compared with those obtained with pure  $\text{CaS}$ . Naphthalene, anthracene, heavy oils, toluene and benzene increased the yields of cabbage. Their influence on godetias was not so pronounced, crude anthracene, in the amt. used, even acting unfavorably. Mixts. of  $\text{CaS}$  and the above aromatic hydrocarbons were beneficial. The conclusion is drawn that partial sterilization hinders the development

of animal and vegetable parasites in addition to bringing about a better utilization of the soil's reserves by the plant.

ALBERT R. MERZ.

**Azofication.** J. E. GREAVES. *Soil Science* 6, 163-217(1918).—A general discussion of the subject of nitrification and a review of the literature are given. A bibliography of 211 references is appended. It is concluded that the part played by *Azotobacter* in maintaining the N of the soil is an important factor. It is estd. that these organisms under favorable conditions add 15-40 lbs. of available N to each acre of soil yearly.

J. J. SKINNER.

**The importance of mold action in the soil.** S. A. WAKSMAN. *Soil Science* 6, 137-55(1918).—A review of literature and a discussion of the subject. The conclusion is drawn that molds take an active part in the decompn. of carbohydrates in the soil. The molds do not fix any appreciable amt. of atm. N. A list of 62 references is appended.

J. J. SKINNER.

**The influence of the cultivation of an upland bog soil on its microbial activity.** TH. ARND. *Mitteilungen des Vereins zur Förderung der Moorkultur im Deutschen Reiche*. 35, 269(1917); *Biedermanns Zentr.* 47, 105-7(1918); cf. *C. A.* 11, 1708.—All samples taken from uncultivated, raw and strongly acid upland bog soil at depths of 5 to 20 cm. contained microbes capable of ammonifying organically combined N. The putrefactive power of the soil is very small as a result of soil conditions and the consequent small number and effectiveness of the putrefying bacteria. The measures involved in cultivation, especially liming, brought about a very marked increase of ammonifying activity. The ammonifying power of a mineral soil used for comparison exceeded during the first year that of the more strongly limed bog soil. Nitrifying bacteria were not present in the raw, uncultivated bog soil nor during the first year in portions of it limed up to 1500 kg. CaO per hectare. Liming to the extent of 2 tons CaO per acre gave the soil a small nitrifying activity which was much less than that of the check mineral soil. Bacteria are present in the raw acid soil which can reduce nitric and nitrous salts with or without the liberation of N. Cultivation and liming increased the  $\text{NO}_3^-$ -destroying activity in proportion to the amt. CaO added. The denitrifying power of the strongly limed soil soon corresponds with that of a mineral soil of neutral reaction rich in microbes. *Azotobacter* organisms are not present in raw acid upland bog soil nor had they colonized during the first year upon cultivated areas either weakly or strongly limed. *Bac. amylobacter* was found in all samples of uncultivated and cultivated bog soil. Tubercle bacteria were present in only a few samples of raw uncultivated bog soil. No verifiable transfer of tubercle bacteria had taken place during the course of a half year from an inoculated soil to neighboring cultivated bog areas.

ALBERT R. MERZ.

**Are unusual precautions necessary in taking soil samples for ordinary bacteriological tests?** C. B. LIPMAN AND D. E. MARTIN. *Soil Science* 6, 131-6(1918).—Soil samples taken to a depth of 5 ft. with an ordinary soil auger and by the "aseptic" method from a flamed vertical wall of a pit, show no significant dissimilarity in bacterial counts, ammonifying power for peptone, nitrifying power and nitrogen-fixing power. It is concluded that for ordinary bacteriol. work on soils, no special precautions are necessary in taking soil samples. It was observed that in the 2 soils studied large bacterial numbers were found at relatively great depths, both samples being from the arid regions.

J. J. SKINNER.

**Bacterial toxins in soils.** R. GREIG-SMITH. *J. Agr. Victoria* 16, 119-20(1918).—An excerpt from a former paper (cf. Brit. Assoc. Adv. of Science, 1914). Aq. exts. of soils, filtered through porous porcelain and seeded with *B. prodigiosus*, are used to det. the presence of toxins. Attention is called to the fact that it is not always easy to demonstrate the presence of toxins, but some of the conditions under which they are

not to be expected to respond to the test have been fully established by investigations. "For example, they are destroyed by exposing the soil to the sun, by heating the soil, by storing the soil in the air-dry condition; they decay rapidly in aq. soln. and are destroyed upon boiling. They are sol. in  $H_2O$  and are washed out of the soil by rain." Evidence is offered to show that there are at least 2 kinds of toxins in soils: one which predominates in the soil, is thermolabile; the other, in the subsoil, is thermostable.

R. B. DEEMER.

**Report on the examination of commercial cultures of legume-infecting bacteria.** C. R. FELLERS. *Soil Science* 6, 53-67(1918).—Of 32 samples, 2 cultures were classed as poor. The general condition of the cultures examd. was very good. Soy beans were more difficult to inoculate than most of the common legumes. It was found that heat, light and exposure do not affect soil cultures as much as agar or liquid cultures. The plate method of testing pure cultures was used, the results being verified by growing the plants and examg. the roots for nodules.

J. J. SKINNER.

The effect of inoculation, fertilizer treatment and certain minerals on the yield, composition and nodule formation of soy beans. C. R. FELLERS. *Soil Science* 6, 81-119(1918).—Inoculation gave an increase in yield of total dry matter and of seed of soy beans. From vegetation and field tests it was found that some commercial cultures were ineffective while others are as efficient in producing nodules on the host plant as freshly isolated cultures of *B. radiculicola*. The protein content of soy beans was increased and the oil content decreased by inoculation, in direct proportion to thoroughness of infection of the plant. The progress of *B. radiculicola* in soil from area to area is very slow. Liming acid soils in amts. of 1000 to 2000 lbs. per acre increased production of soy beans and stimulated nodule production. The oil content of soy beans decreases and protein increases in direct proportion to the largeness of application of lime. Acid phosphate exerted a beneficial influence on protein formation in seed. On limed soil it caused an increased growth, increased nodule formation and oil content of seed. One hundred to 200 lbs. per acre was as beneficial as larger amts. KCl caused only a small increase of growth and nodule formation and a slight decrease in oil content of seed.  $NaNO_3$  inhibited nodule formation, caused an increase in protein content in seed and a decrease in their oil content.  $MnSO_4$  stimulated germination and early growth of soy beans, but did not stimulate nodule production nor give increased yields; it had practically no effect upon the oil or protein content of the seed. The protein content of soy beans is increased by applications of 100 pounds of S per acre; larger amts. caused decreases. Oil content of seed was increased by S. The field expts. were conducted on Penn. fine sandy loam and on acid Sassafras sandy loam. The pot expts. were on Penn. fine shaly loam, mixed with varying amts. of a coarse quartz sand.

J. J. SKINNER.

**Tests of commercial cultures for legume inoculation.** H. A. NOYES AND C. O. CROMER. *Soil Science* 6, 69-77(1918).—The object of this work was to det. the amt. of inoculated soil to use per acre and to test relative efficiency of soil and commercial cultures, and the effect of fertilizers on inoculation. With sweet clover both soil and commercial cultures, when dild. so that each obtained either its exact proportion of the culture or of the bacteria in the inoculated soil used, gave successful inoculation, soil and culture being equally efficient. With other crops inoculation was not secured under the conditions of the expt. Fertilization with  $NaNO_3$  tended to reduce the percentage of inoculation secured. The investigation comprized pot and greenhouse plot tests.

J. J. SKINNER.

**The description of environment as a basis for the judgment of its influence upon plant growth.** H. VATER. *Intern. Mitt. Bodenk.* 6, 159, 209, 293(1916); *Biedermanns Zentr.* 47, 100-3(1918).—As the result of a study of the literature in which

the observation of plants for ecological study, the food-dissolving secretions of roots and expts. to det. analytically the content of nutritive matter, and the description of environment as a basis for the estn. of its influence on plant growth are critically considered, the conclusion is reached that a thorough description of the influence of soils on plants can only be given by means of a geological basis of classification of the soils. A complete description of environment comprizes the particulars demanded in "Anleitung zur Standorts- und Bestandsbeschreibung beim forstlichen Versuchswesen" (1908), the results of soil investigations as well as, in case the root space lies in the sphere of influence of the ground water or the soil is exposed to regular inundations, the chem. analysis of the waters concerned. The relationship between the growth of plants and the environment can only be learned by investigating thoroughly in a sufficiently large number of places both the environmental conditions and the plant growth. The investigation of such places must include, beside the description of environment, growth expts. for the detn. of the sufficiency of plant foods and these must be carried out on the place itself as pot expts. are insufficient. The extn. of ash constituents and N compds. from the soil by plants is conditioned on (1) the effort of the plant to take up food elements in proportions dependent upon its species, (2) the amt. of available food constituents in the soil, (3) the weather. There is no solvent whose effect upon the soil completely coincides with the solvent power of plants. It is impossible to det. the fertility of a soil even with respect to a single plant species by a comparison of the food constituents of the soil in question with a fixed scale of constituents. The detn. of these constituents is however the starting point of the investigation of the influence of environment on plants. The investigation must be carried out separately for each combination of plant species and soil variety and rests in part directly and in part indirectly upon all characteristics of the environment. A classification of soils cannot be made to meet all requirements and different classifications must be used according to the purpose. In the estimation of plant growth with respect to the plant food content of the soil Liebig's law of minimum must be observed. The plant food content of soils of like variety can be strictly compared only when the food present in least amt. is known and is the same in the soils to be compared. An exhaustive bibliography is given.

ALBERT R. MERZ.

Conversion of quicklime in soil. G. HAGER. *J. Landw.* 65, 245-311(1917); *J. Chem. Soc.* 114, I, 247.—When CaO is added to soil only a small part reappears as CaCO<sub>3</sub>, the remainder being adsorbed by the soil, and no Ca(OH)<sub>2</sub> being recoverable even after very short digestion. The adsorption may be due to surface action or to chemical causes, and is associated with the observed increased adsorptive power of the soil for other bases (K and NH<sub>4</sub>) which results from an application of lime. The adsorptive power of the soil appears to be related to its content of clay and the presence of unsatd. compds. and normally an equil. is soon reached between the adsorptive and absorptive power of the soil CO<sub>2</sub> and the soil compds., resp. With CaCO<sub>3</sub>, the action is slower and months may pass before equil. is reached. The influence of CaO on the physical character of the soil is also discussed.

L. J. GILLESPIE.

The effect of liming on crop yields in cylinder experiments. J. G. LIPMAN AND A. W. BLAIR. *Soil Science* 6, 157-60(1918).—The need of lime is shown in an expt. in which the soil was fertilized for a number of years with acid phosphate, KCl, (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> and dried blood, using a rotation of corn, oats, wheat and timothy.

J. J. SKINNER.

The effect of a different ratio of lime and magnesia on plant growth. O. LEMMER-MANN AND A. EINECKE. *Landw. Jahrb.* 50, 617-48(1917); *Biedermanns Zentr.* 47, 111-4(1918).—Pot expts. were conducted with a natural soil containing 0.2739% CaCO<sub>3</sub> and 0.2939% MgCO<sub>3</sub>, sol. in 10% HCl. Pots 1-3 (I) received no further CaO

fertilization (ratio  $\text{CaCO}_3$ : $\text{MgCO}_3$  1:1); pots 4-6 (II) received 60.78 g. limestone giving a ratio  $\text{CaCO}_3$ : $\text{MgO}_2$  of approx. 3:1; pots 7-9 (III) received 31.39 g. limestone and 29.38<sup>g</sup> g. magnesite giving a ratio of  $\text{CaCO}_3$ : $\text{MgCO}_3$  1:1; pots 10-12 (IV) received 8 g.  $\text{CaCO}_3$ , 52.78 g.  $\text{MgCO}_3$ , making the ratio 1:2.3. All pots were also fertilized with 10 g.  $\text{KH}_2\text{PO}_4$ , 6.3 g.  $\text{K}_2\text{SO}_4$  and 10 g.  $\text{KNO}_3$ . Oats were used as the crop and rye grass as a second crop after a supplementary fertilization with 0.66 g. N. The results of the expts. show that the yields of series I and III which contained relatively the same ratio of lime and magnesia but in different absolute amts. are approx. the same. They also show that no particular ratio can be deduced which acts most beneficially on oats and rye grass. The ratio 3:1 which in one year gave the highest yields gave no higher yields than the other series the following year. A second set of expts. was conducted with quartz sand. Ten kg. sand per pot received 1.5 g.  $\text{KH}_2\text{PO}_4$ , 0.7 g.  $\text{K}_2\text{SO}_4$ , 4.0 g.  $\text{NaNO}_3$ , 0.2 g.  $\text{NaCl}$ , and 0.12 g.  $\text{FeCl}_3$ . To these marble dust and magnesite were added to give the following series:

|                       | I.  | II. | III. | IV. | V.  |
|-----------------------|-----|-----|------|-----|-----|
| $\text{CaCO}_3$ ..... | 9   | 7.5 | 5    | 2.5 | 1   |
| $\text{MgCO}_3$ ..... | 1   | 2.5 | 5    | 7.5 | 9   |
| Ratio.....            | 9:1 | 3:1 | 1:1  | 1:3 | 1:9 |

Oats were first raised but were harvested early because of a failure of the crop. Rye grass was raised the next year. The only conclusion to be drawn from the oat expt. is that the high  $\text{MgO}$  had an injurious effect. This was not shown with rye grass. The final conclusions drawn are: It is apparent that there exists an optimal ratio not only of lime and magnesia but between still other food elements. Since we can not yet ascertain these relations and are not in a position to det. the soils' content of assimilable food elements in order to produce a proper ratio of food elements, furthermore do not sufficiently exactly know the relative minimum of the plant food elements for plants, the figures given by Loew can have no general significance. This is confirmed by many expts. Attention is called to the significance of the law of the minimum with respect to the problem.

ALBERT R. MERZ.

**Fertilizers.** A. BAGULEY. *J. Chem. Met. Min. Soc. S. Africa* 18, 301-3 (1918).—A reply to discussion of B.'s paper (*C. A.* 12, 1095). The view is advanced that the effect of free S applied to the soil is due to its effect on microscopic soil flora and fauna, brought about by partial sterilization of the soil.

ALBERT R. MERZ.

**The effect of unbalanced fertilizers, especially unbalanced potash fertilizers.** W. SCHNEIDERWIND. *Illust. landw. Ztg.* 37, 493-4 (1917); *Biedermanns Zentr.* 47, 109-11 (1918).—The results of fertilizer expts. on plots that had previously received no  $\text{P}_2\text{O}_5$  in 14 yrs. show that the influence of  $\text{K}_2\text{O}$  together with N and  $\text{P}_2\text{O}_5$  was greater than that of  $\text{K}_2\text{O}$  with N alone but that  $\text{K}_2\text{O}$  with N increased the yields over those obtained with  $\text{K}_2\text{O}$  only. On plots that had previously received no N for 14 yrs. the effect of a potash-phosphate fertilizer with N was considerably greater than without N. The potash-phosphate fertilizer alone brought about noteworthy increases of yield. The rendering available of the soil-N and the soil- $\text{P}_2\text{O}_5$  by potash salts can take place only in restricted measure and cannot possess practical significance, as is shown by  $\text{P}_2\text{O}_5$  and N detns. in culture plants not fertilized with  $\text{K}_2\text{O}$ . The effect of unbalanced potash fertilizers is therefore solely a  $\text{K}_2\text{O}$  effect. The  $\text{NO}_3$ -forming effect of  $\text{CaO}$  fertilization is not to be over-estd. because most cultivated soils contain the amts. of  $\text{CaO}$  necessary for it. Crops exptd. with were sugar beets., potatoes, wheat and barley.

A. R. M.

**Gravimetric estimation of phosphates.** W. R. MUMMERY. *Analyst* 43, 324 (1918).—The following modification of Ullmann's method has been used successfully for a number of yrs. in the analysis of guano and fertilizers. After digestion, filtration of the  $\text{HNO}_3$  soln. must be made before it is made up to standard vol. Ppt. phospho-

molybdates at 60° and allow to stand for 30 min. at 60°. Ppt.  $\text{MgNH}_4\text{PO}_4$  at 80° and allow to stand for 3 hrs. at room temp.

H. M. LANCASTER.

**The residual effect of superphosphate.** G. S. GORDON. *J. Dept. Agr. Victoria* 10, 610-7(1918).—Data taken from the Victorian Year Book 1913-14, show that in 1898 only 7% of the land under cultivation was fertilized with phosphate; this has increased year by year. In 1913, 77% of the cultivated land was fertilized. In 1913, 219,423 tons of rock phosphate and 105,612 tons of superphosphate were used in Victoria. Expts. at the Werribee Farm show that superphosphate used in amts. of 50 to 200 lb. per acre gave large increase in crop production. The residual effect on the second crop was also very marked.

J. J. SKINNER.

**Injurious effect of borax in fertilizers on corn.** S. D. CONNER. *Proc. Indiana Acad. Sci.* 1917, 195-9.—A com. fertilizer containing 5% of  $\text{K}_2\text{O}$ , 5% of available  $\text{P}_2\text{O}_5$ , and 2.35%  $\text{H}_3\text{BO}_3$  proved harmful to corn in pots when used in amts. of 100 lbs. per acre. Fifty lbs. per acre caused no damage. The damage was caused by preventing germination, by bleaching the leaves of the young corn and by stunting or killing the young plant. An artificial fertilizer made in the lab. so as to contain the same amt. of  $\text{K}_2\text{O}$ ,  $\text{P}_2\text{O}_5$  and  $\text{H}_3\text{BO}_3$  had the same detrimental effect as did the com. fertilizer. Field observations substantiated the results of the pot test. The effect varied somewhat with the character of the soil.

J. J. SKINNER.

**Ten years' cultivation and replanting of varieties of potatoes upon the experimental farm of Pentkowo from 1907 to 1916.** IHLE, DORHLER AND BIELER. *Frühlings Landw. Ztg.* 1917, Nos. 17 and 18, 337 pp.; *Biedermanns Zentr.* 47, 121-5(1918).—To test the widespread opinion that varieties of potatoes degenerate with continued cultivation, 16 varieties were raised and replanted for 10 consecutive years. The soil, fertilizer additions and planting conditions are described. The replanted varieties found satisfactory conditions for growth at Pentkowo and were enabled to furnish as high or higher yields than the "original seed stock" (i. e., potatoes grown from seed obtained elsewhere and not from seed grown on the exptl. field). Comprehensive tables are given comparing for each of the 16 varieties the crop yields of the "original seed stock" and of the "replanted" potatoes during the successive years. Lack of  $\text{K}_2\text{O}$  in fertilizer showed itself quite markedly in comparison with complete fertilizer application. This was much less if at all the case with  $\text{P}_2\text{O}_5$  and even with N. Lack of  $\text{K}_2\text{O}$  fertilization caused not only a diminution of yields but also decreased the deposition of starch in the tubers. Potatoes of the series "without  $\text{P}_2\text{O}_5$ " showed a higher starch content. This was also shown by an additional expt. with 8 varieties raised with and without  $\text{P}_2\text{O}_5$  fertilization, which indicated that  $\text{P}_2\text{O}_5$  cannot increase the starch content of the tuber. The increase of yield per acre was for the av. of the 8 varieties with the "original" as well as with "replanted" potatoes greater upon the  $\text{P}_2\text{O}_5$  plots than upon those "without  $\text{P}_2\text{O}_5$ ." Further expts. are in progress to ascertain the influence of  $\text{P}_2\text{O}_5$  upon protein content. No criteria could be observed from which to draw conclusions upon the differences in behavior of the "original" and "replanted" varieties toward  $\text{P}_2\text{O}_5$ .

ALBERT R. MERZ.

**Powdery mildew of the apple.** W. J. ALLEN AND W. LE GAY BRERETON. *Agr. Gas. N. S. Wales* 29, Pt. 6, 408-12(1918).—A study of the use of FeS, lime-sulfur, Bordeaux mixture, and a proprietary fungicide, called atomic sulfur. Removal of affected wood and terminal eyes accompanied by spraying with FeS was most effective. Details of the time for spraying are given and the method of prepg. the FeS is described.

R. B. DEEMER.

**Copper fungicides for vine diseases.** F. DE CASTELLA. *J. Dept. Agr. Victoria* 16, 592-9(1918).—The chem. of Bordeaux mixt., its physical nature, and its effect on vine diseases are discussed.

J. J. SKINNER.

Composition of the irrigation waters of Utah (GREAVES, HIRST) 14. Production of acid phosphate from creamery waste sulfuric acid (CARR) 12. The peanut (KERLE) 12. Fertilizers from sewage sludge (U. S. pat. 1,284,441-2) 14.

TRUFFANT, G.: Production des legumes. Versailles: by the author.

Fertilizer. G. A. R. BORGHESE, *et al.* Can. 187,572, Nov. 26, 1918. Phosphoric material, potash material and  $\text{NaHSO}_4$  are mixed and heated to fusion, the fused mass is then ground. It is sol. in a 2% citric acid soln.

Fertilizer. G. A. R. BORGHESE and G. STAMPA. Swiss 77,804, June 1, 1918. In the manuf. of a fertilizer containing K phosphate in a form sol. in a 2% citric acid soln., a mixt. of  $\text{Ca}_3(\text{PO}_4)_2$  and Al K silicate is fused in a furnace with a small amt. of a flux such as  $\text{NaHSO}_4$ ,  $\text{H}_2\text{SO}_4$ ,  $\text{CO}_2$ , Cl, F, or a ferruginous or manganiferous compd. as a constituent of one of the minerals employed.

Fertilizer. J. H. CONNOR. U. S. 1,283,677, Nov. 5. A fertilizer is prepd. by mixing blast furnace flue dust containing Fe and K compds. and salt residue and calcining the mixt. to convert the K compds. present into sol. or available state.

Fertilizer. J. H. CONNOR. U. S. 1,283,678, Nov. 5. A fertilizer is produced by boiling a mixt. of bone phosphate of lime, tobacco stems, animal refuse and  $\text{Na}_2\text{CO}_3$  under steam pressure, drawing off the resulting liquor and boiling it down. Slag, flue dust and phosphate rock also may be used.

Fertilizer. A. F. DELACOURT. U. S. 1,282,385, Oct. 22. A fertilizer containing available phosphate and K compds. is produced by heating a mixt. of  $\text{Ca}_3(\text{PO}_4)_2$ , leucite or other K-bearing silicate rock and free  $\text{SiO}_2$ , to a temp. of about 1000-1100°.

Fertilizer. N. A. BARBIERI. U. S. 1,282,170, Oct. 22. See Brit. 110,338 (C. A. 12, 399).

Fertilizer containing available phosphoric anhydride and potash. R. F. GARDINER. U. S. 1,282,805, Oct. 29. A mixt. of  $\text{CaCl}_2$  and minerals such as apatite or orthoclase is heated with sawdust or other wood waste at a bright red heat to obtain a mixed fertilizer.

Rendering phosphates citrate-soluble. E. C. SOPER. U. S. 1,281,681, Oct. 15. Insol. Ca phosphate, to be rendered citrate-sol., is pulverized and mixed with sufficient  $\text{H}_2\text{O}$  (about 40% the wt. of the phosphate) to form a plastic or fluid mixt. To this mixt. there is added an amt. of  $\text{Na}_2\text{CO}_3$  or  $\text{Na}_2\text{SO}_4$  equal to about 15% the wt. of the phosphate. This mixt. is then rapidly heated in thin layers so that the moisture is flashed into vapor and a porous solid residue is obtained which is subjected to a temp. high enough to produce reaction with formation of citrate-sol. phosphate.

## 16. FERMENTED AND DISTILLED LIQUORS.

ROBERT H. WAHL.

Manufacture of spirit from molasses. E. GALLE. *Z. angew. Chem.* 31, I, 3-4, 6-7 (1918).—Fermentation by beer yeast is the only method of obtaining a satisfactory yield of alc. from molasses containing raffinose. Under certain conditions gum-like substances may be formed while the presence of a large amt. of salts or especially of certain salts may cause a bad fermentation; nitrites and fatty acids have a strong restrictive influence.  $(\text{NH}_4)_2\text{PO}_4$  is added in some molasses distilleries to give a more vigorous growth. It is well to apply fermentation tests to the molasses and to store it and use it according to the results of these tests. A convenient test is as follows:

Dil. a quantity of molasses corresponding to 42 g. by polariscopic test with 300 cc. of  $H_2O$ , neutralize with  $N H_2SO_4$ , add 3 cc. additional, and then treat with 30 cc. of a yeast culture which has been fermented down to 7 saccharimeter degrees. Connect the flask with a Hayduck's app. charged with  $H_2SO_4$  and keep at  $30^\circ$ . A good sample of molasses should give 0.5 g.  $CO_2$  after 6 hrs., 1.5 g. after 12 hrs., and at least 4 g. after 18 hrs. From results of these tests and from the alkalinity molasses may be classified into three groups; (1) requiring 4 cc. of  $N$  acid per 100 cc. for neutralization and yielding 4 to 6 g.  $CO_2$  in 18 hours; (2) alkalinity 5 to 8 cc., yielding 3 to 4 g.  $CO_2$ ; (3) alkalinity over 8 cc., yielding less than 3 g.  $CO_2$ . Molasses which has undergone acetic or butyric fermentation is sometimes neutralized with soda or lime, but such products ferment badly. For fermentation of molasses a yeast acclimatized to HF is the most suitable, but attempts to acclimatize beer yeast to HF have been unsuccessful. A good yeast culture is prepd. as follows: Neutralize 10 g. of molasses with  $H_2SO_4$ , dil. to  $38^\circ B$ , boil, cool and after 48 hrs. boil again. Treat 170 cc. of this liquid with 70 cc. of  $(NH_4)_2PO_4$  and 10 cc. of approx. 0.2  $N$  HF and 25 cc. of a resin soap soln., made by boiling 100 kg. of resin with 20 g. KOH in 500 l. of water, and dilg. the soln. to  $4^\circ B$ . Make up this liquid to one liter in a fermentation flask and treat with 60 cc. of pure yeast culture, keeping the flask at  $19^\circ$  and drawing a slow current of sterilized air through the liquid. After 24 hrs. the liquid will have fermented down to 7 saccharimeter degrees and more cultivations can be made from it until an amt. is obtained large enough to use  $\frac{3}{4}$  of it for pitching the molasses. The yeast cultivation from one ton being introduced into the second and so on, it is possible to ferment good molasses down to  $6^\circ$  in 12 to 14 hours, but it is necessary to keep the temp. from rising above  $30$  to  $32.5^\circ$ .

J. K. DALE.

**Determination of glycerol in wines.** MAURICIO CANÓNICA. *Anales soc. quim. Argentina* 6, 94-101 (1918).—C. proposed the following modified Laborde-Pasteur procedure in the case of wines containing less than 5% sugar: Fifty cc. of wine, after addition of approx. 100 g. of No. 4 Pb shot and 10 drops concd.  $H_2SO_4$  are concd. on a sand bath to approx. 3 cc.; after cooling there are gradually added to this 2-3 g. (an amt. approx. equal to that of the ext.) of finely powdered  $Ca(OH)_2$ . The mass is agitated with the shot and the final consistency should be neither too stiff nor too fluid; more  $Ca(OH)_2$  should be added if necessary. After several mins. the glycerol is extd. with 75 cc. of a mixt. of 1 vol. 95% alc. and  $1\frac{1}{4}$  vol.  $Et_2O$ , care being taken to keep the mass in suspension in the liquid in the form of a thin paste. The liquid is decanted, the residue is extd. with 40 cc. of the  $Et_2O$ - $EtOH$  mixt., the liquid is again decanted and the residue is finally washed with 30 cc. of  $Et_2O$ - $EtOH$ . In the case of wines containing 5-20% of sugar the procedure is the same as before with the exception that the original liquid is not concd. to quite such an extent; the  $Ca(OH)_2$  must be added very gradually with const. agitation and the mass should be moistened with 50% alc. if it is too stiff in consistency. The same proportion of  $Ca(OH)_2$  is used as before and extn. with  $Et_2O$ - $EtOH$  is the same. In the case of wines containing more than 20% sugar extn. is more difficult. Fifty cc. of wine are concd. as before (after addition of Pb shot and  $H_2SO_4$ ) to a sirupy consistency (approx. 50% of ext.). After coolin  $Ca(OH)_2$  is very gradually added in the same proportion as before (i. e., in amt. approx. equal to the amt. of ext. in the original 50 cc. of wine) with const. agitation, 50% alc. being used to moisten the mass so as to form a thin paste. The latter is treated with 120 cc. of 80% alc. (added gradually with agitation) and the whole is then heated to approx.  $75^\circ$ . After cooling the liquid is decanted on a filter and the residue of Ca saccharate is carefully washed 2-3 times with hot 80%  $EtOH$ , the total amt. of  $EtOH$  employed being approx. 250 cc. After adding 10 cc. of  $H_2SO_4$  the alc. ext. is evapd. to several cc.; approx. 2 g.  $Ca(OH)_2$  are added and the resulting paste is extd. with  $Et_2O$ - $EtOH$  as in the preceding cases. The  $Et_2O$ - $EtOH$  soln. obtained in the

preceding cases is concd. by evapn. and, when a sirupy consistency is obtained, the residue is heated  $1\frac{1}{2}$  hr. (approx. the time required for drying glycerol containing 15% of  $H_2O$ ) at  $70^\circ$ , cooled and weighed. The weighed residue is dissolved in  $H_2O$  and the soln. is evapd. to dryness at  $180^\circ$  (sand bath), the wt. of the residue being subtracted from the original wt. and the difference reported as glycerol. The procedure suggested by Laborde (carbonizing the glycerol with concd.  $H_2SO_4$  at  $150^\circ$  and washing and weighing the resultant C) is not recommended because (among other reasons) of the organic impurities which accompany the glycerol; in addition it is difficult to avoid reduction of  $H_2SO_4$  by the C. C. gives results of analyses in which the preceding methods were tested by detg. glycerol before and after addition of glycerol to vermouth and wines of various types. The methods were also tested by detg. glycerol before and after addition of large proportions of sugar to wines and comparison was also made with the official German method for detn. of glycerol in wines. Satisfactory results were obtained, considering the errors naturally inherent in such methods.

H. S. PAINE.

**Utilization of Argentina raw materials.** JUAN B. TERÁN AND JOSÉ LUCAS PENNA. *Univ. Tucumán inform. depart. investig. industr.* 1917, 21-5.—T. and P. discuss a plan developed by the Univ. of Tucuman for the study from a technical standpoint of means of utilizing the resources of Argentina in various raw materials. The systematic utilization of corn and potatoes for manuf. of alcohol is recommended and the possibility of using alc. denatured with  $C_6H_6$  as a source of power for automotive vehicles to replace gasoline is discussed from a technical standpoint.

H. S. PAINE.

**Alcohol.** KELLOG TOASTED CORN FLAKE CO. Can. 185,862, July 30, 1918. Roasted or burnt starch is washed to dissolve out the sol. ingredients, the insol. ingredients are converted into maltose and dextrins, the latter are inverted into fermentable sugars, the liquor is fermented and alc. is sepd. out.

**Alcohol.** THE ACME LABORATORIES. Can. 185,743, July 30, 1918. Lactic fermentation of whey renders the unfermented lactose therein susceptible to alc. fermentation. The lactose soln. is then treated with sucrose in a state of fermentation to decompose the lactose with the sucrose.

**Alcohol.** B. KAZMANN. Brit. 119,333, Nov. 15, 1917. Alc. is prepared from burnt or roasted cereals or starchy materials such as result from fires in grain elevators, etc., or are formed as residues in processes for making coffee substitutes by extg. with  $H_2O$  roasted legumes, nuts, tubers such as taro or arrowroot, starch-bearing roots, fruits such as figs, prunes, or bananas, seeds such as cottonseed or St. John's bread, Algaroba beans, soy beans, or grains such as yeast, rye, barley, corn, Kaffir corn, or rice. The material after being washed or heated to expel substances which retard fermentation, is treated with a diastatic material such as malt, *Aspergillus oryzae*, etc., the mash or the liquid ext. is heated with  $H_2SO_4$  to convert the dextrin into fermentable sugar, and the liquid is cooled, fermented, and distd. Cf. C. A. 12, 1812.

**Caramel for coloring liquors.** A. DANIEL. Swiss 77,801, June 1, 1918. In the manuf. of caramel, which is readily sol. in  $H_2O$  and alc., and which colors rum, cognac, and liquors without turbidity, carbohydrates are heated with HOAc with the addition of dehydrating agents. The caramel is pptd. from the soln. by  $Na_2CO_3$  or NaOH.

## 17. PHARMACEUTICAL CHEMISTRY.

W. O. EMERY.

An institute for coöperative research as an aid to the American drug industry. *J. Ind. Eng. Chem.* 10, 969-76(1918).—This is a report of a symposium before the

New York Section of the Am. Chem. Soc. in which are reproduced the following addresses: "A national institute for drug research," by JOHN J. ABEL. An institute of chemotherapy, by P. A. LÉVENE. Drug research and the Bureau of chemistry, by C. L. ALSBERG (in abstract form). An institute for research in synthetic organic chemistry, by A. S. LOEVENHART. An institute of therapo-chemical research, by FRANK R. ELDRED. Institute for research on synthetic drugs, by D. W. JAYNE. Remarks concerning suggestion for central medicinal research laboratory, by E. R. WEIDLEIN. E. J. C.

Conditions essential for the commercial manufacture of carvacrol. A. W. HIXSON AND R. H. MCKEE. *J. Ind. Eng. Chem.* 10, 982-92(1918).—The essential results of the investigation are summarized as follows: The process for producing carvacrol from cymene as derived from spruce turpentine has recourse to the following necessary operations: (1) Making cymenesulfonic acid by thoroughly agitating the turpentine with an equal vol. of 66° Bé.  $\text{H}_2\text{SO}_4$  at a temp. of 90-100° for 4 hrs. in a cast-iron sulfonating kettle. (2) Neutralization of the excess  $\text{H}_2\text{SO}_4$ , formation of Ca cymenesulfonate in soln. by adding ground  $\text{CaCO}_3$  to the sulfonation products and removal by filtration of the  $\text{CaSO}_4$  formed. (3) Formation of Na cymenesulfonate by adding soda ash to the hot filtrate and removal by filtration of the pptd.  $\text{CaCO}_3$ . (4) Conc. of the Na cymenesulfonate soln. in a vacuum evaporator to the point of satn. (5) Pptn. and drying of the Na cymenesulfonate by means of a rotary steam-heated film dryer, or other suitable method. (6) Fusion of the dry Na cymenesulfonate with approx. one-half its wt. of 76% NaOH in a cast-iron or steel fusion kettle provided with a cover and condenser at a temp. of 350-70° for 6 hrs. (7) Pouring the fused product into a minimum amt. of cold  $\text{H}_2\text{O}$ , and subsequent neutralization with just enough 40° Bé.  $\text{H}_2\text{SO}_4$  to fix the excess NaOH and to set free the carvacrol from its Na salt. (8) Separation of the carvacrol by steam distn. or by agitation with a solvent, as benzene. (9) Recovery of solvent by distn. (10) Distn. of the carvacrol from the benzene ext. with a direct by heated still. (11) Fractionation of the carvacrol from the same still. This process was tested on a large scale and found to give better results than when tested in a small way. W. O. E.

Constituents of oil of cassia. F. D. DODGE. *J. Ind. Eng. Chem.* 10, 1005-6 (1918).—In addition to previously known constituents of this oil, D. has identified benzaldehyde and methyl salicylaldehyde in 2 samples recently examd. W. O. E.

Ephedrine and pseudoephedrine. E. SCHMIDT. *Mon. sci.* 8, 151-9, 197-206 (1918).—A bibliography and résumé of work accomplished in this field, especially by S. and his co-workers. W. O. E.

The evaluation of balsam of Tolu. T. T. COCKING AND J. D. KETTLE. *Am. J. Pharm.* 90, 719-22(1918); cf. *C. A.* 8, 3346; 12, 2229.—It is pointed out that the method of the Brit. Pharm. 1914, for the estn. of the balsamic acids in balsam of Tolu is unsatisfactory. The results obtained are low, as much of the aromatic acid present is combined with resin alcs. and is insol. in, and thus not extd. by,  $\text{CS}_2$ . Boiling out of the aromatic acids with MgO and  $\text{H}_2\text{O}$ , in the presence of a small quantity of xylene to soften the resinous matter, was found to be the most satisfactory way of dealing with the balsam. The Mg salts of the aromatic acids are readily sol. in cold water, those of the resin acids being insol. A complete sepn. is effected and the aromatic acids are obtained in a purer condition than by aq. extn. alone. The procedure is as follows: (1) *Free balsamic acids*: Dissolve 5 g. of the balsam in 25 cc. hot alc. in a 250-cc.  $\text{CO}_2$  flask, add 5 g. of light MgO and 20 cc. xylene and shake the flask round until the contents are well mixed. Add 100 cc.  $\text{H}_2\text{O}$ , connect the flask to a reflux condenser and boil for 1 hr. After cooling, pour the whole on a Büchner filter, and sep. the aq. portion of the filtrate from the xylene layer, which is returned to the

flask together with the filter paper and adhering magnesia-balsam magma. Add a second 100 cc. of water and again boil for 1 hr. Then sep. the aq. portion of the filtrate as before and carry out the extn. a third time. Wash the bulked aq. liquids once with 20 cc.  $\text{Et}_2\text{O}$ , then render acid with  $\text{HCl}$  and ext. the pptd. acids by shaking out with  $\text{Et}_2\text{O}$ . Dist. off the greater part of the  $\text{Et}_2\text{O}$ , dry the residual aromatic acids *in vacuo* over  $\text{H}_2\text{SO}_4$  and weigh. (2) *Total balsamic acids*: Saponify 2.5 g. of the balsam by boiling with excess of alc.  $\text{KOH}$ ; then evap. off most of the alc., dissolve the residue in 100 cc. hot  $\text{H}_2\text{O}$ , and add sufficient  $\text{HCl}$  to render the whole slightly acid. Next add 5 g. of light  $\text{MgO}$  and 20 cc. of xylene and boil the whole under a reflux condenser for 1 hr. Sep. the aq. liquid repeat the extn. twice, and treat the bulked aq. liquid as in the case of the free balsamic acids. For detn. of cinnamic acid in the mixt. use the bromination method (De Jong, C. A. 4, 559). W. G. GAESSLER.

*Essential oil of artemisia annua* L., especially the portion which boils at high temperature. S. TAKAGI. *Yakugaku Zasshi* (J. pharm. soc. Japan) No. 439, 665-76(1918).—The raw material used in the expt. is a light reddish yellow transparent viscous oil. From 500 g. oil, 52 g. colorless oil  $b_p$ , 125-130° and 98 g. light yellow oil  $b_p$ , 130-170°, were obtained by fractional distn. The first fraction purified by distg. over  $\text{Na}$  and  $\text{K}$ , consists chiefly of a portion  $b_p$ , 122-3°,  $d_{14}$  0.89416,  $n_D^{14}$  1.50435,  $[\alpha]_D^{13}$  -87.65°. Analysis gives the formula  $\text{C}_{14}\text{H}_{24}$ . By passing dry  $\text{HCl}$ ,  $\text{HBr}$  and  $\text{HI}$  into the oil, cadinene hydrohalides, and by hydration with Bertram and Wahlbamm's method, isocaryophenylhydrate m. 96° were obtained. A sesquiterpene alc. of the formula  $\text{C}_{14}\text{H}_{22}\text{OH}$  or  $\text{C}_{14}\text{H}_{20}\text{OH}$ ,  $b_{14}$ , 168-171°, was sep'd. from the second fraction by fractional distn. It has the following physical properties:  $d_{11}$  0.9497,  $n_D^{21}$  1.50882,  $[\alpha]_D^{21}$  +12.41°. It is sol. in  $\text{EtOH}$  and forms an Ac compd. on heating with  $\text{Ac}_2\text{O}$  and  $\text{AcONa}$ . S. KOMATSU.

Some observations on the solution of zinc chloride and several suggested solvents J. C. AND B. L. DE G. PEACOCK. *J. Am. Pharm. Assoc.* 7, 689-97(1918).—Several  $\text{Zn}$  salts are employed in therapy, chiefly as lotions, injections, mouth washes and eye washes. The solns. are usually in  $\text{H}_2\text{O}$  and contain but a few grains of the  $\text{Zn}$  salt per fl. oz.  $\text{ZnCl}_2$  frequently does not dissolve well owing to the formation of  $\text{Zn}(\text{OH})\text{Cl}$ . This forms a bulky ppt. which renders the prepn. unsightly. If the soln. be filtered the correct amt. of  $\text{Zn}$  salt is not present. The addition of  $\text{HCl}$  causes complete soln. but this is frequently not permissible. Hot  $\text{H}_2\text{O}$  does not solve the difficulty. Complete soln. may be obtained by the addition of  $\text{H}_3\text{BO}_3$  or of  $\text{NH}_4\text{Cl}$ . In therapy one or the other of these may usually be allowable. The presence of  $\text{NaCl}$ , as in physiologic salt soln., does not interfere. Also in *Am. J. Pharm.* 90, 706-17(1918).

L. E. WARREN.

The manufacture of aspirin tablets. R. C. WHITE. *J. Am. Pharm. Assoc.* 7, 697-700(1918).—A discussion.

L. E. WARREN.

The effect of alcohol on the activity of liquor hypophysis. P. S. PITTINGER. *J. Am. Pharm. Assoc.* 7, 831-2(1918).—It has been asserted that the presence of small amts. of  $\text{EtOH}$  destroys the physiol. activity of the soln. From the results of a series of expts. P. concludes that the belief is unfounded.

L. E. WARREN.

Brazilian jalap and some allied drugs. O. A. FARWELL. *J. Am. Pharm. Assoc.* 7, 852-5(1918).—Botanical and pharmacognostical descriptions of the market supplies of *Piptostegia pisonis*, *Resina drastica* and *Ipomoea orizabensis*. F. believes that the plant from which Brazilian jalap is derived should be named *Operculina macrocarpa* L. *Resina drastica* is from an undetd. botanical source, but its characteristics indicate that it is derived from some member of the *Convolvulaceae*. The resin from Brazilian jalap is yellow; that from *Resina drastica* is black.

L. E. WARREN.

**Piptostegia root, *Piptostegia pisonis* Mart.**, so-called "Brazilian jalap." C. O. EWING AND J. F. CLEVELAND. *J. Am. Pharm. Assoc.* 7, 855-8(1918).—A root offered for importation as "jalap" was not the true drug but the root of *Piptostegia pisonis* Mart. The spurious drug assayed 23% of resin by the U. S. P. method for jalap. The resin was of a light tan color and conformed to the U. S. P. tests for jalap resin except for a slight excess in acidity and the formation of a greenish color with 10%  $\text{NH}_4\text{OH}$   $\alpha_D$   $-48.5^\circ$ . Specimens of the resin were extd. with various solvents. Pet. ether dissolved 2.1%,  $\text{Et}_2\text{O}$  5.4%,  $\text{CHCl}_3$  73.4%,  $\text{EtOAc}$  14.2%, and  $\text{EtOH}$  4.7%. A comparison of these solubilities with the records for the resins of scammony, jalap, Mexican scammony and morning glory shows that this resin differs markedly from them all, the most striking difference being in its much greater soly. in  $\text{CHCl}_3$ . Only about 25% of the true resin of jalap is sol. in  $\text{CHCl}_3$ . Large doses of the resin produced emesis without catharsis in dogs. Smaller doses produced catharsis without emesis.  
L. E. WARREN.

High-melting-point fatty acids and other products from wool-fat or similar substances (U. S. pat. 1,284,723) 27.

MAY, PERCY: **The Chemistry of Synthetic Drugs.** 2nd Ed. Revized and enlarged. London: Longmans, Green & Co. 250 pp. 10s. 6d.

**Oxycholesterol.** I. LIFSCHÜTZ. U. S. 1,284,724, Nov. 12. Oxycholesterol is made by dissolving cholesterol in  $\text{CHCl}_3$  or  $\text{CCl}_4$  and treating the soln. with a mild oxidizing agent such as benzoyl peroxide and heating to the b. p. for 2-10 hrs.

**Guaiacol.** E. H. ZOLLINGER. U. S. 1,281,662, Oct. 15. In the manuf. of guaiacol, 11 g. of pyrocatechol is intimately grated with 25 g. of  $\text{KCH}_3\text{SO}_4$  and mixed with 15 g. of veratrol. To this mixt., 25 g. of  $\text{NaHCO}_3$  is added in portions during 2 hrs. at a temp. of  $160-180^\circ$ . Upon cooling, the reaction product is acidified and subjected to steam distn. A yield of 10.5 g. of guaiacol may be recovered from the distillate.

**Dry non-hygroscopic lime product.** J. A. WÜLFING. Holl. 2,432, Apr. 15, 1918. A mixt. of Na and Ca lactate, in the proportion of 2 to 1, is incorporated with the lime in granular form, the mass being then dried.

**Therapeutically active derivatives of *p*-aminophenol.** SOC. ANON. POUR L'IND. CHIM. À BAËLE. Swiss 78,043-5, July 1, 1918. Addition to 76,619, (C. A. 12, 2411). Derivs. of *p*-aminophenol are obtained by treating *p*-aminophenyl allyl ether with formylating agents, or by heating it with a compd. containing the lactic acid radical, or by treating it with a compd. containing the radical of isovaleric acid, or by treating it with *o*-bromoisovaleryl halides. The properties of the products are specified.

**Product for coagulating blood.** SOC. ANON. POUR L'IND. CHIM. À BAËLE. Swiss 77,601, June 1, 1918. In the prepn. of a coagulant for blood from beer yeast, the latter is boiled with alc., whereby the coagulation of the yeast albumin and other chem. changes are effected. After the addition of  $\text{H}_2\text{O}$ , the alc. is expelled by distn. *in vacuo*, and the resulting emulsion is shaken with ether, acetone is added, the resulting ppt. is filtered off and again extd. with ether, and the ethereal soln. is evapd. to dryness *in vacuo* with pulverized sugar. Cf. C. A. 12, 2111.

**Inulin for therapeutic use.** A. DANIEL. Swiss 77,857, June 1, 1918. In a process of obtaining inulin from plants, in a form suitable for therapeutic use, the albuminous and deleterious substances are sepd. by the addition of strongly alk. substances and with heating. The solns. must be kept strongly alk.

**Iron-albumin compound.** K. KOTTMANN. Swiss 78,276, July 1, 1918. Albumin from altered animal cell material is treated with substances containing Fe, obtaining an Fe-albumin compd., a well defined substance with the Fe in intimate combination. The product has diagnostic and therapeutic value.

**Alkaloids.** SOC. ANON. POUR L'IND. CHIM. À BÂLE. Brit. 119,287, Sept. 27, 1917. A water-sol. prepn. of the active constituents of ergot suitable for injection is obtained by extg. the drug (previously powdered and freed from oil) first with H<sub>2</sub>O and then with dil. alc. containing a small proportion of a volatile organic acid (H.COOH, HOAc, etc.); the alc. ext. is distd. *in vacuo*, with addition of H<sub>2</sub>O, to remove alc. and excess organic acid; it is then filtered and mixed with the aq. ext. The mixed soln., with or without further purification, is evapd. to dryness, or is concd. and brought to a definite vol.

**Camphor.** DU PONT DE NEMOURS & Co. Brit. 118,489, Sept. 28, 1917. Crude camphor is purified by heating in a closed retort to 300–500° F., whereby the camphor oil is modified so that it can be sepd. from the camphor, either by dissolving out the camphor with an organic solvent (petroleum spirit, alc., etc.) and crystallizing, or by subliming the camphor.

**Sulfuric acid.** H. V. WELCH. U. S. 1,284,166, Nov. 5. Oxides of N and fumes of  $H_2SO_4$  and nitrosylsulfuric acid are removed from the effluent of the chamber process of making  $H_2SO_4$  by passing the effluent between electrodes between which a high tension elec. field is maintained to effect pptn. upon the electrodes. The pat. describes and illustrates app. for carrying out the procedure. U. S. 1,284,167 describes the manuf. of  $H_2SO_4$  by the contact process. The  $SO_3$  is brought into contact with a spray of dil.  $H_2SO_4$  and the  $H_2SO_4$  mixt. thus formed is pptd. electrically.

**Sulfuric acid.** L. BRADLEY. U. S. 1,284,175, Nov. 5. Dust is electrically pptd. from a gas stream containing  $SO_2$  and  $H_2SO_4$  (such as may be produced by burning pyrites) while a temp. is maintained sufficiently high to avoid substantial deposition of  $H_2SO_4$  and thereafter the gas is cooled to form a cloud or mist containing  $H_2SO_4$  and subjected to a second elec. pptn. to obtain  $H_2SO_4$ . U. S. 1,284,176 specifies electrically pptg. dust from burner gases while maintaining a sufficiently high temp. to avoid substantial deposition of  $H_2SO_4$ , then partially oxidizing the  $SO_2$  in the gases, cooling and subjecting to a second elec. pptn. to recover  $H_2SO_4$ .

**Crystallized phosphoric acid.** J. N. CAROTHERS and W. H. ROSS. U. S. 1,283,398, Oct. 29. ("Dedicated to the public" for free use without payment of royalty.) Phosphorus oxide fumes from any smelting operation are collected electrically in an app. of such radiating surface that the fumes will be pptd. at a temp. above  $100^\circ$  and the collected acid is then allowed to cool to a temp. below its m. p. A solid product is thus obtained.

**Concentrating nitric acid.** B. THOMAS. U. S. 1,283,598, Nov. 5. Concd.  $HNO_3$  is obtained by absorbing nitrogenous gases such as those generated from air in an elec. furnace in a liquid such as  $H_2O$  under pressure and at the same time converting the lower oxides of N into  $HNO_3$  by electrolysis, at a temp. below  $40^\circ$ .

**Sodium cyanide.** H. P. EASTMAN. U. S. 1,282,395, Oct. 22. NaCN is made by melting a mass of NaCl, adding "lime nitrogen" and  $CaC_2$  and maintaining the temp. above  $900^\circ$  (preferably over  $1100^\circ$ ) until reaction is complete.

**Sodium cyanide.** H. FREEMAN. U. S. 1,282,405, Oct. 22. In the production of NaCN by fusing a mixt. containing NaCl and "lime nitrogen," the fused product, as it runs from the furnace, is rapidly cooled to such a temp. as to avoid decompn. of the NaCN produced. The product may be obtained in the form of flakes containing NaCN,  $CaCl_2$ , NaCl and free lime.

**Ammonium perchlorate.** E. A. LESUEUR. U. S. 1,284,380, Nov. 12.  $NH_4ClO_4$  is formed by heating an aq. soln. of  $(NH_4)_2SO_4$  and  $NaClO_4$  to a temp. slightly above that at which substantial sepn. of hydrated  $Na_2SO_4$  occurs, as a result of which copious formation of  $NH_4ClO_4$  takes place, sepg. the liquid from the crystals, dilg. the liquid and chilling it to effect crystn. of hydrated  $Na_2SO_4$ , leaving  $NH_4ClO_4$  in soln.

**Sodium and aluminium hypochlorites.** E. E. DURR and P. C. DURR. Brit. 119,261, Aug. 22, 1917. In a process of mfg. Na and Al hypochlorites, Na aluminate is first produced by heating a mixt. of calcined bauxite, NaCl,  $\text{Ca(OH)}_2$ , and C to redness in a retort in a current of  $\text{As}_2\text{O}_3$  vapor.  $\text{AsCl}_3$ , H, and  $\text{CaCO}_3$  also are formed, the  $\text{AsCl}_3$  being condensed and employed for the manuf. of Cl for use later in the process. The residue is lixiviated and the soln. of Na aluminate is divided into 2 parts into one of which  $\text{CO}_2$  is passed until the pptn. of  $\text{Al(OH)}_3$  is complete. The  $\text{Na}_2\text{CO}_3$  is filtered off and employed for the production of NaOH for subsequent use in the process. The ppt. of  $\text{Al(OH)}_3$  is mixed with the remainder of the Na aluminate and Cl is passed into the mixt. till all the Al has passed into soln. as hypochlorite. The HCl formed is neutralized with NaOH soln. which is added in sufficient quantity to ppt. Al as hydroxide with production of NaOCl. The  $\text{Al(OH)}_3$  is filtered off, mixed with  $\text{H}_2\text{O}$  and converted into hypochlorite by passing Cl into the liquid. The NaCl produced is crystd. out from the solns. of the hypochlorites.

**Alkali dichromates.** SOC. INDUSTRIELLE DE PRODUITS CHIMIQUES. Brit. 119,219, Jan. 25, 1918. Alkali dichromates are obtained by treating monochromates with  $\text{CO}_2$  in the presence of  $\text{H}_2\text{O}$  with or without an org. solvent of the dichromate such as EtOH, MeOH or acetone. The alkali bicarbonate is sepd. by means of its slight soly. in solns. of dichromate, particularly in the presence of the above mentioned org. solvents.

**Potassium chloride.** E. A. ASHCROFT. Brit. 119,492, Aug. 28, 1917. KCl is obtained from potash-bearing minerals such as feldspar, mica, alunite, or leucite, or from cement-kiln dust, blast-furnace dust, wood or plant ashes, beet-sugar residues, etc., by treating the substances with Cl gas while suspended in a fused bath of Na or K chloride, or a mixt. A Cl carrier such as a salt of Fe, Mn, or Cr, and a reducing agent such as C or Na, K, Zn, Pb, or Fe sulfide may be added. The reaction is carried out in a converter at about  $800\text{--}1100^\circ$  and may be continued until some constituents, which form volatile chlorides such as Fe or Al, are sepd. by volatilization. KCl is sepd. by lixiviation.

**Anhydrous calcium chloride.** E. A. ASHCROFT and B. T. PLUMLEY. Swiss 78,103, June 17, 1918. Cl is allowed to act upon a Ca compd. in a molten bath, in the presence of C and of a Cl carrier serving as a catalytic agent. The principal reaction is illustrated by the equation  $2\text{CaO} + \text{C} + 2\text{Cl}_2 = 2\text{CaCl}_2 + \text{CO}_2$ . A secondary reaction is  $2\text{FeS}_2 + 3\text{Cl}_2 = \text{Fe}_2\text{Cl}_6 + 4\text{S}$ . The catalytic reaction proceeds in two phases:  $\text{Fe}_2\text{Cl}_6 + 3\text{CaO} = 3\text{CaCl}_2 + \text{Fe}_2\text{O}_3$  and  $2\text{Fe}_2\text{O}_3 + 6\text{Cl}_2 + 3\text{C} = 2\text{Fe}_2\text{Cl}_6 + 3\text{CO}_2$ .

**Potassium salts from kelp.** S. R. OPPENHEIM. U. S. 1,283,547, Nov. 5. K salts obtained from kelp or similar materials and containing org. substances are freed from the latter by filtering a soln. of the impure salts through bone char.

**Soluble potassium compounds from siliceous minerals.** J. H. STOVER. U. S. 1,283,951, Nov. 5. Orthoclase or a similar K-bearing mineral is finely pulverized, mixed with an alkali metal carbonate, hydroxide or oxide and fused at a red heat. About 1.5 times as much  $\text{K}_2\text{CO}_3$  as orthoclase may be employed, and, if desired, powdered coal or other combustible may be added to assist the fusion. If the rock is powdered to 200 mesh, the reaction may be effected at a sintering temp. Any alkali which is volatilized is condensed in the stack and recovered. The reaction mass is run into  $\text{H}_2\text{O}$  and may be agitated with steam or compressed air to dissolve the  $\text{K}_2\text{CO}_3$ , KOH and K silicate, leaving in suspension a finely divided silicate of K and Al which may be decomposed by acid. For the latter purpose, chamber  $\text{H}_2\text{SO}_4$  is suitable if but small amts. of alk. earth metals are present in the residue, but if larger amts.

of alk. earth metals are present HCl is preferably used to avoid formation of insol. salts. The silicic acid obtained in the last mentioned step is filtered out and may be treated with NaOH to form Na silicate. As an alternative procedure, alumina can be pptd. by use of KOH and can be filtered out with silica. The alumina can be then dissolved with an acid and, after filtering, the silica will remain in such form that it will readily form waterglass on boiling with an alkali.

**Phosphorus or its compounds from mineral phosphate.** W. H. WAGGAMAN, C. R. WAGNER and H. BRYAN. U. S. 1,282,994, Oct. 29. A charge of phosphate, siliceous material and coke is fed down through a vertical shaft constituting the inner chamber of a furnace, upon a table where it is heated by means of burning fuel which may either be mixed with the charge or may be otherwise supplied. The products of combustion and the volatilized products are then led out through a chamber surrounding the inner or charging shaft and the P and phosphoric acid are recovered in any desired manner. An app. is described for carrying out the operation. Oil, coal or gas may be used as the fuel.

**Recovering phosphorus fumes from phosphate rock.** A. R. MERZ, W. H. ROSS and J. N. CAROTHERS. U. S. 1,284,200, Nov. 5. The P evolved from phosphate rock by the volatilization method is recovered by introducing into the fumes of the P oxides a substance (such as  $\text{NH}_3$ , steam or KCl) which will react with the fumes, and the resulting compd. is collected on a filter.

**Utilizing niter cake.** J. GROSSMANN. Brit. 119,290, Sept. 28, 1917. The reaction between finely powdered niter cake and  $\text{NaNO}_3$  or  $\text{NaCl}$  to produce  $\text{HNO}_3$  or HCl is effected in the presence of coal, coke, or other carbonaceous matter in fairly large pieces (about half an in. in diam. or more) in order that the resultant salt-cake shall be friable and easily removable, while the reducing action of the coke etc. is small. The reaction is carried out as described in 111,875 (C. A. 12, 855) and 114,180 (C. A. 12, 1501). In making HCl, the temp. may be raised in the later stages to 350-450°.

**Separating alumina and silica.** C. M. HALL. U. S. 1,282,222, Oct. 22. Aluminous materials of high  $\text{SiO}_2$  content, such as clays or low-grade bauxites are mixed with NaCl in the proportion of about 4 mols. NaCl to each mol. of  $\text{Al}_2\text{O}_3$  present and the mixt. is passed through a furnace wherein it is exposed to steam. HCl is evolved and the solid compn. containing Na aluminosilicate is mixed with lime and soda and this mixt. is heated to about 700-760° for 2-3 hrs. to produce sol. Na aluminate and insol. Ca silicate, which may then be sepd. by leaching.

**Agglomerate.** G. FREY. Swiss 78,065, June 17, 1918. Solid particles are imbedded in a slurry of MgO,  $\text{MgCl}_2$ ,  $\text{MgSO}_4$  and  $\text{Al}_2(\text{SO}_4)_3$ . E. g., a mixt. of sawdust and MgO is agglomerated by means of a soln. of  $\text{MgCl}_2$  of 32° Bé a soln. of  $\text{MgSO}_4$  of 30° Bé and a soln. of  $\text{Al}_2(\text{SO}_4)_3$  of 28° Bé.

**Nitric oxide from internal-combustion engines.** R. DRAWE. U. S. 1,283,112, Oct. 29. In operating internal-combustion engines to produce nitric oxide, highly heated steam, air or other gas is injected into the fuel mixt. to increase the heat of the latter in proportion to its vol., the high temp. of the mixt. is maintained up to the end of the compression stroke, to effect formation of nitric oxide, combustion being completed when the highest temp. is reached. The rapid fall of temp. thereafter minimizes decompn. of the nitric oxide formed.

**Nitrogen and carbon dioxide.** C. D. McCOURT. Can. 187,662, Nov. 26, 1918. Accelerated surface combustion of an explosive gaseous mixt. of fuel and air is effected, the  $\text{CO}_2$  is absorbed from the combustion gases by contact with carbonate liquor and the N is sepd. from the decarbonated combustion gases. The  $\text{CO}_2$  is removed from the carbonated liquor by heat and the liquor is returned to absorb more  $\text{CO}_2$ .

**Recovering values from alunite.** R. MOLDENKE. U. S. 1,282,273, Oct. 22. Alunite is digested with concd.  $\text{H}_2\text{SO}_4$  in a closed chamber under ordinary pressure and at a temp. of about  $260\text{--}315^\circ$  to effect free evolution of vapors, the mixt. of acid and converted material is withdrawn from the chamber, the solid material is sepd. by settling and dissolved, sulfate is crystd. from the soln. and the crystd. product is calcined in an atm. of  $\text{SO}_2$  and O to produce  $\text{H}_2\text{SO}_4$  and alumina.

**Separating solids from liquids.** P. T. SHARPLES. Brit. 119,288, Sept. 27, 1917. A compn. having constituents of different sp. gr. is mixed with a carrier liquid heavier than at least one of the said constituents and subjected to centrifugal action to sep. the constituents. In a particular example, the lighter constituent is first sepd. from the remainder of the mixt., which may be further subjected to centrifugal action to sep. the carrier liquid, which is heavier than either constituent from the heavier constituent. The carrier liquid may be returned to the app. and used repeatedly.

**Dehydrating emulsions.** F. W. HARRIS. U. S. 1,281,952, Oct. 15. In dehydrating emulsions such as those of  $\text{H}_2\text{O}$  and petroleum oil, electrodes within the emulsion are caused to approach each other sufficiently to cause  $\text{H}_2\text{O}$  chains to be formed between the electrodes through which heavy short-circuit currents can flow. The electrodes are then sepd. and the current interrupted.

**Manufacturing gasblack, hydrogen, etc.** C. D. MCCOURT. Can. 187,661, Nov. 26, 1918. Methane is forced through a highly heated porous and permeable bed of refractory material where it is decompd. into gasblack and H. These are sepd. The temp. of the bed is maintained by burning the H thus produced.

**Metal-polishing powder free from acid.** E. BEUTEL. Swiss 77,897, June 1, 1918.  $(\text{NH}_4)_2\text{CO}_3$  is added to the metal polish. E. g., 100 parts powdered clay are mixed with 30 parts wood dust and 10 parts  $(\text{NH}_4)_2\text{CO}_3$ , and packed in gas-tight paper.

**Solution of low freezing point.** C. A. LEWIS. U. S. 1,282,249, Oct. 22. A soln. of low freezing point, adapted for use in automobile radiator systems is formed of  $\text{CaCl}_2$  40,  $\text{H}_2\text{O}$  58 and a soln. of glucose, borax and caramel 2%.

**Phenolic condensation products.** T. A. EDISON. U. S. 1,283,706, Nov. 5. *p*-Phenylenediamine in the proportion of 0.5–1.0% is added to the usual ingredients for producing hardened phenolic condensation products upon heating, for the purpose of accelerating the speed of the final hardening reaction.

**Laminated articles containing phenolic condensation product.** L. T. FREDERICK. U. S. 1,284,296, Nov. 12. Solid articles (such as elec. insulation) are formed by building up a rectangular article of laminations of paper and phenolic condensation product which has not been transformed into final insol. form and then applying heat and pressure to the sides and edges of the article to mold and harden it.

**Tubes or rods of sheet material and phenolic condensation product.** L. T. FREDERICK. U. S. 1,284,297, Nov. 12. Tubes or rods adapted for use as elec. insulation are formed by winding a sheet of paper, cloth or similar sheet material, associated with a phenolic condensation product, placing the roll in a heated mold and applying pressure axially to harden and compact it.

**Tubes of fibrous material and phenolic condensation product.** L. T. FREDERICK. U. S. 1,284,298, Nov. 12. Tubes adapted for use as elec. insulation are formed by treating paper with a phenolic condensation product which will serve as a binder, winding the dry sheet around a mandrel without applying heat or pressure to build up a tubular body and then applying heat and pressure so as first to soften and then to harden the phenolic condensation product.

**Electrical insulating material from fibrous sheets and phenolic condensation products.** L. T. FREDERICK. U. S. 1,284,644, Nov. 12. A decorative insulating material is formed by building up a laminated body of differently colored sheets of paper or other fibrous material and phenolic condensation product, shaping the laminated material and, while clamped in the desired shape, subjecting it to the action of heat and pressure simultaneously.

**Laminated articles from fibrous sheet material and phenolic condensation product.** D. J. O'CONOR, JR. U. S. 1,284,432, Nov. 12. Sheets of paper, muslin, or other fibrous material are treated with a phenolic condensation product which is capable of being solidified by the action of heat and pressure, the treated sheets are superposed upon each other, subjected to heat and pressure and during the last stage of this treatment the heat is increased and the pressure is lowered. This produces a product which is adapted for use as an elec. insulating material.

**Tubes of fibrous material and phenolic condensation product.** W. H. KEMPTON. U. S. 1,284,363, Nov. 12. Tubes suitable for use as elec. insulation are formed by winding upon a mandrel a sheet of paper or other fibrous sheet material treated with a phenolic condensation product, and then applying pressure to the entire inner surface of the tube and heating it while under pressure.

**Electrical insulating material.** L. T. FREDERICK. U. S. 1,284,295, Nov. 12. Composite tubes for use as an elec. insulating material are formed of wound sheet material such as paper treated with a phenolic condensation product. The outer turns are treated with shellac varnish to give the tubes greater strength than they would otherwise have. The assembled sheet material, after being wound upon a mandrel, is heated to at least 90°.

**Compositions for printers' rollers.** J. L. BASSECHES. U. S. 1,284,172, Nov. 5. The object of the invention is the production of printers' rollers which may be recast and which may be made without glycerol or with a smaller amt. of glycerol than usually employed previously. Mixts. of this character are made of glue, H<sub>2</sub>O and beet molasses (or a sirup containing only small amts. of monosaccharides) with or without glycerol, resins, varnishes or oils. Suitable mixts. may, *e. g.*, be formed of glue 30%, beet molasses 35%, glycerol 20% and H<sub>2</sub>O 15%; or from glue 30%, beet molasses 50%, H<sub>2</sub>O 15% and resin oil varnish 5%. Worn out rollers of these compns. may be cut into small pieces, remelted, mixed with about 15% of new material and recast. The beet molasses used is refined by successive treatment with dil. H<sub>2</sub>SO<sub>4</sub> and with powdered CaCO<sub>3</sub>.

**Waterproof cement.** H. M. OLSON. U. S. 1,283,546, Nov. 5. About 1% of animal, vegetable or mineral oil, tallow, wax or similar dry oleaginous material, in anhydrous condition, is ground with dry cementitious material such as a lime or gypsum plaster to prep. a waterproof cement.

**Sound-record.** J. W. AYLSWORTH. U. S. 1,283,450, Nov. 5. Sound-records are formed with a hard surface material capable of softening slightly when heated, *e. g.*, a phenolic condensation product, a backing of material more plastic when heated than the surface material and a sheet of fabric between the surface and backing materials. The backing may be formed of wood flour 50-100 and fusible phenolic condensation product or shellac or rosin 50-100 parts.

**Gramophone records.** C. C. H. MILLAR. Brit. 119,477, Jan. 3, 1916. Disk records are formed of finely ground wood, not in the form of pulp, with or without the addition of flock or shoddy and binding material such as shellac. The dry material is submitted to a jiggling operation to produce a level surface, is damped by H<sub>2</sub>O or steam, and is then slightly compressed to form a disk. The disk may then be

dried and subjected to higher pressure in an hydraulic press. Coloring matter may be added.

**Lubricant.** CHEM. FABRIKEN WORMS AKT.-GES. Swiss 78,279; July 1, 1918. An aq. soln. of a lactate is incorporated with graphite. E. g., 100 parts of an aq. soln. of Na lactate of sp. gr. 1.35 are worked up in a ball mill with graphite to a uniform paste of the desired consistence. The product as thus obtained is ready for use and is permanent.

**Decolorizing material.** R. M. CATLIN. Can. 186,173, Aug. 20, 1918. Decolorizing material is produced by subjecting the residues from slate distn. to the action of HF.

**Calcining granular material.** C. D. McCOURT. Can. 187,659, Nov. 26, 1918. Granular material is continuously fed through a furnace chamber, an explosive gaseous mixt. having combined with it a reagent capable of combining with the charge is injected at a speed greater than that of backfiring and accelerated surface combustion is effected within the charge to heat it and effect chemical changes. The hot combustion gases are passed through the material being fed into the furnace.

**Vegetable glue.** R. W. TUNNELL. U. S. 1,284,495, Nov. 12. An adhesive suitable for uses generally to which vegetable adhesives are adapted is formed of low-grade tapioca 80, high-grade tapioca 20 and  $ZnCl_2$  or other Zn salt 0.1-0.25 part. Cf. C. A. 12, 1693, 2116.

## 19. GLASS AND CERAMICS.

G. E. BARTON, A. V. BLEININGER.

The second annual report of the delegacy for glass research, University of Sheffield. ANON. *J. Soc. Glass Tech.* 2, 155-70(1918).—In the glass expt. work pots of 28, 56 and 100-200 lbs. capacity are used. Much testing and exptg. for glass mfrs. has been done. General descriptions are given of the courses at Univ. of Sheffield and of the research problems, completed, under way and contemplated. C. H. KERR.

The effect of continued action on chemical glassware of water, acid and alkali. J. D. CAUWOOD AND W. E. S. TURNER. *J. Soc. Glass Tech.* 2, 235-9(1918).—The short-time soly. tests were repeated many times (10 to 25) on representative Zn-Al borosilicate, Al borosilicate, and Na-Ca chem. glasses. **Conclusions:** The Na-Ca glasses obtain a somewhat more resistant surface by continued treatment with either  $H_2O$  or HCl. The borosilicate glasses improve slightly in resistance to  $H_2O$ , but are unchanged in resistance to continued action by HCl. None of the glasses improves in resistance upon continued treatment with either caustic or carbonated alkali. The irregularities found show the folly of drawing conclusions from one or two tests. These variations are thought to be due chiefly to actual lack of homogeneity in the glass and not to exptl. errors. C. H. KERR.

The resistant properties of some types of foreign chemical glassware. J. D. CAUWOOD AND W. E. S. TURNER. *J. Soc. Glass Tech.* 2, 219-35(1918).—Tests previously made (cf. C. A. 12, 212-13) are continued with 11 additional samples, of which 1 is Japanese (K), 5 American (L, M, N, O, T) and 5 German (P, Q, R, S, U). The samples are as follows: K = Japanese; L = Nonsol; M = Insolo; N = Fry; O = Pyrex; P = Resistance "R;" Q = Kohn-Ehrenfeld; R = Kavalier; S = German, unmarked; T = Insol; U = Zsolua. The 6 tests previously described were applied, with results shown in the table below, in which the former glasses are also included.

| Class.      | Boiling H <sub>2</sub> O. | H <sub>2</sub> O at 183°. | 2N NaOH.  | N/10 NaOH. | 2N Na <sub>2</sub> CO <sub>3</sub> . | Boiling HCl. |
|-------------|---------------------------|---------------------------|-----------|------------|--------------------------------------|--------------|

*General conclusions:* (1) Chem. glass makers at present rely mainly on Zn-Al borosilicates or Al borosilicates, the former being usually the better. (2) The resistance of Ca-Na glasses is as follows: toward H<sub>2</sub>O and dil. caustic alkali, fair; strong caustic alkali, good; Na<sub>2</sub>CO<sub>3</sub>, poor; acid, excellent. The Na-Ca glasses are therefore of special

value for analytical work, like  $\text{SiO}_2$  in steel where  $\text{HCl}$  is used. (3)  $\text{SiO}_2$  gives resistance to  $\text{H}_2\text{O}$  and acid, but not to caustic or carbonated alkali. (4)  $\text{B}_2\text{O}_3$  increases resistance to  $\text{H}_2\text{O}$  up to a mol. ratio of about 12 per 100  $\text{SiO}_2$ .  $\text{B}_2\text{O}_3$  lowers resistance to alkali and  $\text{HCl}$ . (5)  $\text{CaO}$  is not, in general, an important ingredient and should be avoided when  $\text{Na}_2\text{CO}_3$  will be used in the vessel. (6) Large amts. of alkali are to be avoided because they decrease resistance to  $\text{H}_2\text{O}$ , acid and alkali. (7)  $\text{Al}_2\text{O}_3$  seems to be a valuable all-round constituent. (8)  $\text{ZnO}$  is in high favor but specific proofs of its great value are not yet found. The  $\text{ZnO}$  glasses are very good in general results. (9) There is no proof as yet of the value of  $\text{MgO}$ . Chem. glassware should be selected with its particular use in mind.

C. H. KERR.

**Compression strength of glass and quartz.** G. BERNDT. *J. Ind. Eng. Chem.* 10, 942(1918).—A borosilicate glass showed 15,200 kg./sq. cm. when in strained condition and 16,900 kg./sq. cm. when well annealed. Quartz showed 25,000 to 27,000 kg./sq. cm. when tested at right angles to the optical axis but much less parallel to the axis.

C. H. KERR.

**Notes on the formation of certain rock-forming minerals in and about glass furnaces.** G. V. WILSON. *J. Soc. Glass Tech.* 2, 177-216(1918).—Most of the samples examd. were taken from a tank which burst and from which 70 tons of metal drained out. Other samples were glass-house pots, bricks and blocks. Very complete descriptions are given of the various minerals and their modes of formation. Optical data are particularly complete. The author's conclusions from his examn. are "(1) Under certain conditions, wollastonite, augite, tridymite, and quartz can all crystallize out from the same melt. (2) Feldspar, magnetic oxide, and biotite are formed by the corrosive action of hot molten glass on common brick. (3) Wollastonite, melilite, an artificial compd. with the formula  $3\text{CaO} \cdot 2\text{SiO}_2$ , and augite are produced in limestone fragments enclosed in molten glass by contact alteration assisted by the absorption of a certain amt. of soda and silica from the glass. (4) Several types of cryst. material were produced, varying from dark bottle glass containing a few isolated wollastonite spherulites to a rock-like substance made up essentially of slender crystals of wollastonite up to 1 inch in length. (5) Absence of pseudowollastonite shows that the temp. of the molten glass when crystallization started cannot have been above  $1190^\circ$  (the inversion temp. of pseudowollastonite to wollastonite). (6) Absence of cristobalite indicated that the temp. was at no time so high as  $1450^\circ$  (the inversion temp. of cristobalite to tridymite). (7) The presence of an amethyst-colored glass rich in Mn shows the general idea held by glass manufacturers, that Mn sinks to the bottom of the tank, to be correct. (8) The presence of quartz crystals in some of this amethyst material leads to the conclusion that the latter remained fluid to a temp. below  $870^\circ$  (the inversion temp. of tridymite to quartz). (9) The absence of quartz in the main body of the glass shows that it had solidified about  $870^\circ$  or become too viscous to allow of crystallization. (10) From (8) and (9) it follows that the amethyst material remained fluid longer than the ordinary green material. This is also proved by the fact that it occurs as a thin strip at the junction of the ordinary material with brickwork, as if the latter had cooled and contracted away and permitted the former to run in to fill up the space." From the investigation of block, pot and brick samples he concludes "(1) Corundum and sillimanite are the minerals usually formed, together occasionally with feldspar, magnetite, and biotite. (2) Corundum is abundant in the fused, glassy surfaces of bricks used in the crowns of furnaces. (3) The white, porcelain-like layers of pots and bricks is often packed with minute needles of sillimanite. (4) The formation of corundum and sillimanite is beneficial, especially so when sillimanite is formed in the inner, vitrified surfaces of glass pots, and also of tank blocks. The network of sillimanite needles acts as a protective coating between the ordinary clay body of the pot or tank

and the contained molten glass. (5) Sillimanite is only developed in pots which vitrified, and the pots which have lasted longest usually contain the greatest development of sillimanite. Burnt aluminous clays generally contain sillimanite, siliceous clays practically never. (6) Since sillimanite seems to be beneficial, it appears that to aid its formation the clays used for the manufacture of pots and furnace blocks should be as aluminous as possible, but should also be capable of vitrification at the temp. to which they are subjected in the furnace." C. H. KERR.

Some additional notes on pot failure. S. N. JENKINSON AND PERCIVAL MARSON. *J. Soc. Glass Tech.* 2, 175-6(1918).—A common cause of cracks across the bottom is insufficient preliminary burning in the pot arch. A down-draft pot arch and a uniform high temp. burning will correct most of the troubles. The practice of placing bricks under one edge is bad because it distorts the bottom. C. H. KERR.

Note on the firing of glass pots. MORRIS W. TRAVERS. *J. Soc. Glass Tech.* 2, 170-4(1918).—In burning, a pot passes through 3 stages: (1) removing "absorbed" and combined  $H_2O$ , (2) biscuit stage, (3) vitrified stage. In stage (2) the pot is very easily attacked and dissolved by molten glass. Changing from (2) to (3) increases d. from about 1.7 or 1.8 to 2.2 or 2.3, and forms a surface layer of sillimanite. The formation of sillimanite is the effect and not the cause of changes which render the pot material insol. Pots should be fired to complete vitrification before glazing or filling. The temp. required will vary with the material, but usually 3 days at  $1350^\circ$  is sufficient. Care must be taken to keep pots hot at the time of filling. C. H. KERR.

Note on the sintering of magnesia. JOHN B. FERGUSON. *J. Am. Ceram. Soc.* 1, 439-40(1918).—Before the war tubes, etc., of  $MgO$  were imported from Germany. Examn. shows these wares to contain about 2% forsterite ( $2 MgO/SiO_2$ ) and about 1% of other impurities which act as bond. At the Geophysical Lab. a special elec. resistance furnace, of the cascade type, used for some hrs. at  $1600$  to  $1720^\circ$  showed sintering of the silky, calcined pure  $MgO$  used to insulate the 2 heaters. Such sintering was not previously observed when the furnaces were operated at temps. below  $1600^\circ$ . The sintered cake showed, under the microscope, no binding material, only periclase (cryst.  $MgO$ ) with less than  $1\frac{1}{2}\%$  forsterite.  $SiO_2$  content found, on analysis, was 0.44%. The mass showed good strength and it seems feasible to make  $MgO$  ware without binder if the product is fired to  $1600$ - $1700^\circ$  for some hrs. C. H. KERR.

The porosity and volume changes of clay fire brick at furnace temperatures. GEORGE A. LOOMIS. *J. Am. Ceram. Soc.* 1, 384-404(1918); cf. *C. A.* 12, 751.—"Changes in porosity may be said to bear some relation" to deformation under load. The present tests were made in coöperation with the Refractories Manufacturers' Association, and the American Gas Institute. Bricks which resist a load test of 40 lbs. per sq. in. at  $1350^\circ$  show only slight vol. or porosity changes when burned at temps. up to  $1425^\circ$ , while most bricks failing in this load test show rather marked vol. or porosity changes below  $1425^\circ$ . Bricks showing pronounced expansion below  $1400^\circ$ , thus indicating over-burning, invariably fail in the load test. Vol. and porosity changes between  $1350$  and  $1425^\circ$  show, "in a measure" the ability to pass load test. Most bricks showing a porosity decrease of not over 5% and vol. change of not over 3% (about 1% linear) when burned at  $1400^\circ$  will pass the load test, while those with greater changes fail. No definite relation was found between softening point and load-carrying capacity. However, all bricks which softened below cone 28 failed in load test. C. H. KERR.

The calculation of the "rational analysis" of clays HENRY S. WASHINGTON. *J. Am. Ceram. Soc.* 1, 405-21(1918).—Only 4 minerals, kaolin, quartz, feldspar, and mica, need be considered. The rational analysis aims at the detn. of the amts. of these minerals, by treating the clay with various strong reagents. Factors of great importance

which are ignored in rational analysis are (1) kind of feldspar, of kaolin or clay, of mica, etc., (2) size of grain, (3) concn. of reagent, (4) time of digesting, (5) temp. conditions, etc. The results can be nothing more than "approximate and uncertain." The making of the usual ultimate analysis and the calcn. of "norm" compn. is only a little more work and is much more reliable. The method of calculating "norms" or mineral compn. from ultimate analysis is repeated in detail.

C. H. KERR.

The action of acetic acid solutions of different strengths on a sheet steel enamel. LEON J. FROST. *J. Am. Ceram. Soc.* 1, 422-8(1918).—Expts. were made to show whether a 20%  $\text{CH}_3\text{COOH}$  soln. exerts the greatest corrosive action on the vitreous enamel used on kitchen utensils. The test dishes were coated with (1) a coat of ground, (2) a thin coat of white enamel, and (3) a good coating of the glaze tested, the formula for which was 0.885  $\text{Na}_2\text{O}$ , 0.085  $\text{K}_2\text{O}$ , 0.015  $\text{CaO}$ , 0.015  $\text{MnO}$ , 0.263  $\text{Al}_2\text{O}_3$ , 2.291  $\text{SiO}_2$ , 0.452  $\text{B}_2\text{O}_3$ , 0.701  $\text{Fe}_2\text{O}_3$ . The enamel frit was milled with 8% Vallender clay and 1%  $\text{MgSO}_4$ . In each test 25 cc. of the test soln. was evaporated to dryness on a const. hot plate. When dry the dish was removed, cooled, washed, scoured with a soft abrasive, rinsed, dried and weighed. The % of acid and corresponding mg. loss in wt. follow: 1%, 0.0056; 2%, 0.0108; 3%, 0.0127; 4%, 0.0140; 5%, 0.0111; 7%, 0.0088; 9%, 0.0127; 15%, 0.0131; 17%, 0.0140; 18%, 0.0151; 20%, 0.0160; 21%, 0.0214; 24%, 0.0223; 27%, 0.0184; 30%, 0.0132; 40%, 0.0179; 50%, 0.0168; 60%, 0.0117; 70%, 0.0076; 80%, 0.0026; 90%, 0.0013; 100%, 0.0003. From 20 to 25% is most corrosive.

C. H. KERR.

Note on the colors produced by the use of soluble metallic salts. PAUL G. LARKIN. *J. Am. Ceram. Soc.* 1, 429-38(1918).—For years sol. metallic salts have been used in under-glaze color work but their use in over-glaze color especially for terra cotta is recent. Details of manipulation are given, also formulas for green, blue, brown, gray, yellow and orange colors. The method is cheap, satisfactory in quality of work produced, and with proper manipulation gives clean edges. The addition of a Pb frit or flux to a standard-finish engobe properly corrected for the addition, greatly improves the colors produced by sol. salts on standard-finish ware.

C. H. KERR.

Glass. CORNING GLASS WORKS. Brit. 118,397, Apr. 15, 1918. In the manuf. of a glass capable of absorbing ultraviolet rays and as nearly colorless as possible,  $\text{TiO}_2$  and an oxidizing salt are added to the glass compn. The Ti compd. may be used in conjunction with  $\text{CeO}_2$  etc., and  $\text{HNO}_3$  is added to prevent reduction of the oxides.

Glass. CORNING GLASS WORKS. Brit. 118,398, Apr. 15, 1918. In the manuf. of glass capable of absorbing ultraviolet rays and as nearly colorless as possible, V is used, preferably in an oxidized form. The V compd. may be used in conjunction with Ti or Ce compds.,  $\text{MnO}_2$ , etc. Niter may be added to prevent reduction of the oxides.

Silica bricks. SOC. ANON. DES PRODUITS REFRACTAIRES DE L'OUEST. Brit. 118,116, Aug. 6, 1918. Silica bricks are made from any quartz or quartzite contg. an av. of 95%  $\text{SiO}_2$ . After disintegrating or after cooling, the material is subjected to a first crushing and part then reduced to a fine flour by a further crushing. Suitable proportions of the two crushings are mixed together with a binder such as  $\text{CaO}$ , molded, and burned.

Decorating glass surfaces. K. WARGA. U. S. 1,283,606, Nov. 5. In fixing designs upon glass, glass colors are mixed with a soft flux to make the coloring matter fusible at a temp. lower than that required to soften the glass to be coated, the desired design is printed upon decalcomania paper in a fixing agent composed of turpentine oil 108, balsam of fir 50, Pb acetate 3 and soft flux 1 part, heated to produce a sirupy

mixt., the colors are applied to this fixing agent on the decalcomania paper, the glass is coated with a fixing mixt. containing the same ingredients but heated just sufficiently to dissolve the Pb acetate in the mixt., colors are transferred from the design on the decalcomania paper to the fixing agent on the glass and the latter is then heated gradually to a temp. at which fusion of the colors occurs, followed by gradual cooling to near atm. temp.

**Heat-insulating composition.** F. A. HEADSON. U. S. 1,283,754, Nov. 5. Heat-insulating material suitable for furnace walls is prepd. by calcining finely divided diatomaceous earth and finely divided asbestos in the proportions of about 75 to 25 parts, resp., mixing these materials with a binder such as  $H_2O$  and clay and molding the plastic product thus formed and allowing it to harden. The product may finally be burned at a temp. above  $1100^\circ$ .

**Brick-baking process.** THE LAMBERT PROCESS CO. Can. 185,692, July 23, 1918. Bricks are piled in a kiln, part of them are fired for a time with carbonaceous fuel and air is blown into the kiln to burn the remaining bricks.

**Refractory substances.** H. E. MASON and A. COUPER. Brit. 119,101, Sept. 27, 1917. In the manuf. of refractory magnesite bricks, a salt or salts of boric acid and (or) perboric acid in conjunction with one or more of the following fluxing agents: basic slag, Fe oxide, Fe ore, metallic Fe or Fe slag, is incorporated with a mixt. of calcined or raw magnesite and  $H_2O$ . The mixt. is formed into bricks and fired. Alternatively the fluxing agent or agents and borate, etc., are mixed, shaped into bricks, calcined, and ground into powder before being mixed with the calcined magnesite. The av. proportions in 100 parts of mixt. are about 1 part of borate, etc., to about 6 parts of each or any or all of the fluxing agents named.

---

## 20. CEMENT AND OTHER BUILDING MATERIALS.

---

C. N. WILEY.

**The corrosion of iron and steel, with special reference to reinforced concrete.** J. NEWTON FRIEND. *Surveyor* 53, 464-5 (1918).—Curves are given to show the relative corrosion of iron in different solutions. Preservation of iron in concrete may be effected, (1) by complete exclusion of air, (2) by complete exclusion of water, (3) by rendering the concrete sufficiently alk. to place it within the inhibiting area shown in one of the diagrams. W. D. C.

**Stone in 1916.** G. F. LOUGHLIN. U. S. Geol. Survey, *Mineral Resources of the U. S.*, 1916, Pt. II, 993-1078 (preprint No. 36, published Nov. 25, 1918). E. J. C.

**Hydraulic cement.** A. S. DWIGHT and R. L. LLOYD. U. S. 1,283,483, Nov. 5. Finely powdered fuel is thoroughly and intimately intermixed with finely divided raw cement material and this mixt. is deposited in a thin layer pervious to air and covered with a thin layer of slowly burning fuel. This covering of fuel is ignited and air is passed through the entire body of materials to cause combustion of the fuel and sintering of the cement-forming materials.

**Calcium oxychloride cement.** C. CATLETT. U. S. 1,282,188, Oct. 22. A compn. suitable for use as an addition to portland cement to increase its plasticity is formed by effecting reaction between com.  $CaO$  and com.  $CaCl_2$  in the presence of sufficient  $H_2O$  to form a sep. plastic mass, and reducing the latter to pulverulent form while it still contains  $H_2O$  of hydration.

**Hydrating dolomitic or magnesian lime.** C. WARNER and I. WARNER. U. S. 1,284,505, Nov. 12.  $CaO$  containing  $MgO$  is first mixed with sufficient  $H_2O$  to hydrate

the CaO while under atm. pressure and the hydration of the MgO is afterward effected in a closed vessel under pressure. This treatment produces a hydrated material which forms readily worked mortars of good strength.

**Luting composition.** S. TAMARI. U. S. 1,281,702, Oct. 15. An acid-proof luting compn. suitable for use on vessels of reinforced concrete is formed by mixing molten S 1 with graphite 3 parts and stirring and applying the mixt. after heating it to about 170°. Paraffin may also be added to the mixt.

**Potassium compounds from cement flue-dust.** F. S. MOON. U. S. 1,283,261, Oct. 29. Cement-kiln flue-dust containing difficultly sol. K compds. is heated to just slightly below the sintering temp. by contact with hot gases free from siliceous ash. A portion of the K content of the dust is thus volatilized and collected, in sol. form. The residue may be leached or used directly as a fertilizer.

**Tile or paving-block for walls or floors.** H. R. WARDELL. U. S. 1,281,444, Oct. 15. Tiles or similar molded articles are formed of a mixt. of granulated cork 60, sand 20, limestone dust 10 and hard asphalt 10 parts. The limestone dust fills the voids between the larger particles of sand and the sand and limestone dust together fill the voids between the particles of cork.

**Plastic paving composition.** E. L. SHARPNECK. Can. 184,720, June 4, 1918. A compn. for pavement contains a finely divided filler, mineral asphaltum, SiO<sub>2</sub>, iron oxide, Al<sub>2</sub>O<sub>3</sub> and SO<sub>2</sub>.

**Rendering wood dense.** HOLZVEREDELUNG, G. M. B. H. Swiss 78,284, July 1, 1918. The wood is covered with pitch, asphalt, resin, thick glue solns., or the like, and subjected in a suitable vessel to a high pressure at a temp. of 90-150°.

**Preserving wood.** J. A. DECEW. U. S. 1,283,105, Oct. 29. Wood is heated to practically a charring temp. in a soln. of coal-tar pitch to expel the moisture from the wood and impregnate the outer portion with the pitch. The wood is subsequently given a coating of a harder pitch.

**Composition for preserving wood.** J. A. DECEW. U. S. 1,283,104, Oct. 29. A wood-preserving compn. is formed by dissolving rosin and creosote oil in a soap soln. and dilg. this soln. by forcing it into hot H<sub>2</sub>O.

**Treating sweet gum wood to prevent warping.** R. L. GILLIAM. U. S. 1,283,495, Nov. 5. Sweet gum wood is treated to prevent warping and twisting, by the action of steam mixed with an alkali such as Na<sub>2</sub>CO<sub>3</sub> soln.

## 21. FUELS, GAS, TAR AND COKE.

J. D. PENNOCK.

**Santo Tomas cannel coal,** Webb Co., Texas. GEORGE H. ASHLEY. U. S. Geol. Survey, *Bull.* 691-I, 251-70(1918).—This "is probably the largest body of cannel coal of bituminous rank in the U. S., if not in the world." It is a bright, glossy black coal almost like pitch in appearance; firm, yielding 75 to 80% lump as mined and screened over 1.25 inch bars. Chem. analyses show this coal to be high in volatile matter, which averages about 25% higher than the fixed C, the fuel ratio of fixed C divided by the volatile matter being about 0.8. The B. t. u. range is from 11000 to 14000; moisture is remarkably low, about 4%; ash, 16; S, 2; and H, 5.75%. The N content ranges from 0.5 to 1.5%, which suggests distn. for ammoniacal and N derivatives of benzene, but the gas and oil are largely unsatd. hydrocarbons and are given off at such low temps. that the desired N by-products are not obtained. Upon distn. one ton yields 7000 cu. ft. of gas consisting of illuminants, 5.4; CO, 6.6; H, 42.0; CH<sub>4</sub>, 39.0; N, 6; B. t. u.

per cu. ft., 700. The coke residue from distn. contained volatile matter, 5.0; fixed C, 75.0; S, 2.0; ash, 18; B. t. u., 12000; yield of coke, 62%. The mines and operations are described at length.

L. W. RIGGS.

The carbonization of coal. J. W. COBB AND S. F. DUFTON. *Chem. Trade J.* 63, 197-8(1918); *Gas World* 69, 127-32(1918); *Gas J.* 143, 482-7(1918).—In a stream of N rich in  $C_6H_6$  decompn. of the  $C_6H_6$  started at  $550^\circ$  and a small quantity of diphenyl was formed. As the temp. rose it was produced in large quantities together with H. In the material deposited at higher temps. diphenylbenzene occurred. At  $750^\circ$ , 32 g. of these compds. accompanied 115 g. of unchanged  $C_6H_6$ . On using  $C_6H_6$  highly dild. with N, the decompn. was lessened and the yield of diphenyl lowered. On substituting H for the N the decompn. of the  $C_6H_6$  vapor was lessened. By gradually diluting further with H, the amt. of molecular condensates produced at  $750^\circ$  diminished until, when only 8% of benzene vapor was present in the gas mixt., only traces of diphenyl were produced. By further expts. the condensation of  $C_6H_6$  to diphenyl was proved to be reversible. The solid condensates obtained from the  $C_6H_6$ -N mixts. at  $750^\circ$  contained no naphthalene and no unsatd. compds., nor did they yield pitch on distn. Very little C was deposited at  $900^\circ$ , even in high dildn. with H, benzene was freely decomposed with the deposition of gray methane C. On vaporizing  $C_6H_6.CH_3$  and carrying it through coke with a stream of N at  $550^\circ$ , decompn. occurred and at  $600^\circ$  enough stilbene formed to permit of its identification. At the same time an oily substance was formed. At higher temps. increased decompn. was noted and at  $750^\circ$  it was quite extensive. The solid products of decompn. on examination yielded naphthalene and anthracene and consisted partially of unsatd. substances yielding a viscous black liquid on washing with  $H_2SO_4$ . On substituting H for N as the carrier gas, the decompn. of  $C_6H_6.CH_3$  was greatly accelerated with the production of large amts. of  $C_6H_6$  and smaller amts. of solid condensates. The gas collected at the end of the train contained about 50%  $CH_4$ . During coal carbonization, the formation of molecular condensates such as stilbene occurs with liberation of H. If a large quantity of H is present initially the action is checked. By acting directly on the  $C_6H_6.CH_3$ , however, the H atm. reduces it to  $C_6H_6$  and liberates  $CH_4$ . This action is reversible. On passing a mixt. of  $CH_4$  and  $C_6H_6$  through red-hot coke at  $750^\circ$  and examining the products, these consisted of undecomposed  $C_6H_6$  with some diphenyl and a small quantity of  $C_6H_6.CH_3$ . The main difference between the decompn. of  $C_6H_6$  and  $C_6H_6.CH_3$  lies in the action of H. The decompn. of xylene having a b. p. of  $138-40^\circ$  in an atm. of H was similar to that of  $C_6H_6.CH_3$ , yielding  $C_6H_6.CH_3$  and  $C_6H_6$  by reduction and a limited quantity of solid condensates. Cresol, the characteristic constituent of the cresol fraction in tar distn., is also reduced at  $750^\circ$  in a stream of H to  $C_6H_6$  and  $C_6H_6.CH_3$ . By treating the coke from carbonization with steam and H, a considerably larger proportion of  $NH_3$  than is recovered by any ordinary carbonization process is obtained.

E. A. TSCHUDY.

The carbonization of coal. W. SAVAGE. *Chem. Met. Eng.* 19, 579-82(1918).—From  $215$  to  $25^\circ$  F. moisture is removed from the coal, from  $300$  to  $400^\circ$  F. a slight superficial softening of the coal occurs and some gases are given off but the character of the fuel is substantially unaltered. At  $450^\circ$  F. decompn. into paraffin oils, gases, and solid substances begins, the mass fuses, swells and loses wt. and if distn. is completed a porous coal is left. At  $750^\circ$  F. new gases and vapors are liberated accompanied by a marked increase in the volume of the mass, and the development of a very porous cellular structure. At  $825-980^\circ$  F. the liberation of oil is more rapid and in one hr. a 36% vol. coal is reduced to 18% and the apparent sp. gr. of the residue is about 0.75. At very high temps.,  $1500-3000^\circ$  F., the volatile hydrocarbons are practically entirely removed and the C residue is fused to great hardness. For metallurgical coke,

the beehive oven yields a satisfactory product from 32% volatile coals; with by-product coking ovens the best results are obtained by using coals containing 23-8% vol. matter. In the manuf. of carbocoal by the Smith process 30 gals. of water-free tar is produced per ton of 35% volatile coal. This tar contains no naphthalene, anthracene nor carbollic acid but is rich in oils, tar acids and cresols. Standard by-product coke-oven practice produces only 7.5 gals. of tar per ton of raw coal. The Smith process will release vast amounts of petroleum fuel and will furnish great quantities of coal-tar products.

Chem.* 10, 901-10(1918).—A study of the effect of catalyzers on the decompn. of straight-chain hydrocarbons of low mol. wt. The results are given of an investigation of the influence of temp. and pressure on the production of aromatic hydrocarbons.

J. H. YOUNG.

**Quantitative determination of suspended tarry matter.** F. W. STEERE. *Chem. Met. Eng.* 19, 686-9(1918).—After all the methods suggested in the literature for estg. suspended tarry matter in gas had been tried, the "tar camera" was devised and found most satisfactory. The "tar picture" is a piece of special white paper through which a certain amt. of gas has been drawn, the tar being filtered out on the paper and estd. either by comparison with a standard paper or more accurately by weighing under a standard condition of humidity before and after taking the "picture." The "camera" is simple in design; it is merely a pipe tapped into the source of the sample and leading through a cock to an enlarged portion in which are set easily removable gaskets holding the paper. The gas is led out the other side and through a meter or aspirator bottle for measurement. Pictures of the app. together with curves showing the rate of absorption of moisture by paper and its variations with humidity are given. The article also suggests the advantage of removing the tar on a commercial scale by means of electrostatic rather than mechanical methods.

**The formation of coke.** GEORGES CHARPY AND MARCEL GODCHOT. *Compt. rend.* 167, 322-4(1918); cf. *C. A.* 11, 2402.—By the method described in the previous paper, attempts were made to improve the resistant qualities of coke. By mixing 2 coals, with, resp., high and low content of volatile matter, in varying proportions the strength of the coke can be varied. Coke from mixts. with less than 20% of rich coal was very friable; as the % of rich coal increased its strength rose steadily to 80 kg. per sq. cm. at 51%, but fell to 0 at 56%. Another method is to coke the rich coal alone slowly at low temp. (preferably about 450°). A coke of normal strength can often be obtained thus, but too long heating will make it powdery. Still another method is the addition of pitch or tar to a poor coal. Coke with strength as high as 130 kg. per sq. cm. can be obtained in this way. No definite relation can be established

between temp. and time of distn., or % of volatile matter, and the strength of the coke; the optimum conditions for each case must be detd. by expt. I. F. SMITH.

**Fuel-briquet.** C. H. SMITH. U. S. 1,284,939, Nov. 12. Briquets are formed of partially carbonized coal mixed with such a proportion of pitch or a similar binder that the briquet contains 11-17% of volatile materials.

**Briqueting coal.** E. R. SUTCLIFFE. U. S. 1,283,354, Oct. 29. Finely divided coal or similar material to be briqueted is compressed, broken into lumps and again compressed to form blocks or briquets, which are hard and tough. Cf. C. A. 12, 2050.

**Motor fuel.** F. J. H. RUSTIGE. Can. 187,630, Nov. 26, 1918.  $\text{CaC}_2$  in a permeable container is immersed in alc., the proportions of  $\text{CaC}_2$  to alc. being regulated so that the acetylene formed is dissolved in the alc.

**Artificial fuel.** P. LAMBERTY. Brit. 119,443, May 4, 1918. Coal dust, coke dust, and the like are mixed with lime, and the mixt. is damped and molded under high pressure into briquets. These briquets are exposed to the action of steam under pressure in a boiler.

**Producing gas.** B. F. MCKEE. U. S. 1,282,445, Oct. 22. Gas is produced by feeding coal dust or similar carbonaceous material into a rotatable container inclosing a pair of electrodes which gasify the fuel by the action of an electric arc.

**Gas-producer.** C. W. LUMMIS. U. S. reissue 14,548, Nov. 12.

**Gas-producer.** E. A. W. JEFFERIES. U. S. 1,284,694, Nov. 12.

**Gas-producer.** H. C. PERDUE. U. S. 1,284,138, Nov. 5.

**Rectifying still for recovery of benzene and its homologues.** F. TSCHUDY. U. S. 1,282,324, Oct. 22.

**Recovering benzene, toluene and other vaporized or gaseous constituents from coal gas.** R. LESSING. U. S. 1,281,597, Oct. 15. For the purpose of recovering  $\text{C}_4\text{H}_6$ , toluene and their homologs,  $\text{C}_{10}\text{H}_8$  and other hydrocarbons and removing  $\text{CS}_2$  from coal gas, the gas is passed through a closed vessel, which is charged with broken or definite shapes of brick, coke or other porous material such as charcoal, pumice, slag or glass or stoneware previously soaked in heavy tar oil, petroleum oil, pitch or bitumen (from which all low-boiling constituents have been removed by distn.) or S or other suitable substances. The vaporous substances with which the coal gas is more or less satd. and which are liquid at ordinary temps. when isolated are absorbed by the oil. Subsequently steam is blown through the absorption vessel and the vapors thus driven off are led to a condenser and sepg. app. For the removal of  $\text{CO}_2$  from gas, a porous material impregnated with  $\text{Na}_2\text{CO}_3$  may be used. Picric acid may be used as a reagent for selective removal of  $\text{C}_{10}\text{H}_8$ , which is then driven off by superheated steam. An app. is described for carrying out the absorption and distn.

**Heating fusible material by surface combustion.** C. D. MCCOURT. Can. 187,660, Nov. 26, 1918. An explosive gaseous mixt. is injected into and through a fusible material at a speed greater than the normal speed of backfiring. Surface combustion of the explosive mixt. is effected in contact with the molten material which is

agitated by the movement of the gases therethrough. The explosive gases contain a component capable of chemically combining with the fusible material. A modification shows the fusible material fed into contact with a bed of heated refractory material for accelerating combustion.

**Gas for welding and cutting metals.** R. H. BROWNLEE. Can. 187,637, Nov. 26, 1918. A H and hydrocarbon product is made by bringing a suitable hydrocarbon into contact with a highly heated refractory material in an enclosing chamber in the absence of air and a suitable pressure, the product is cooled to sep. the H from the C and gases of the ethylene series may be added.

**Obtaining and distilling oils from coal gas.** D. MARBAIS and C. DEGUIDE. Brit. 118,730, Nov. 1, 1917. Coal gas is washed with an absorbent, the satd. absorbent is distd. for the regeneration of the absorbent, and the vapors obtained by distn. are divided into three fractions, namely 90% benzene, 50% benzene, and a mixt. contg. naphthalene and an oil or spirit of the nature of solvent naphtha. The coal gas is washed with tar oil or anthracene oil in a tower packed with wood shavings, metal waste, shavings and turnings of Fe or steel, etc. App. is specified.

**Ammonia.** A. H. LYMN and N. E. RAMBUSH. Brit. 119,049, June 13, 1917. To sep.  $\text{NH}_3$  from steam and tar contained in producer gas, and to obtain from the  $\text{NH}_3$  clean salts of any acid, the gaseous mixt., after it has been washed in known manner at a temp. of about  $80^\circ$  in  $\text{H}_2\text{O}$  which may contain lime, is passed through a tubular or like condenser, or condensers, arranged to act as reflux condensers, the part of the condenser at which the mixt. enters being kept at such a temp., *e. g.*,  $80^\circ$ , that the steam and tar are simultaneously condensed, but any  $\text{NH}_3$  which condenses with them is immediately volatilized. The other end of the condenser system is kept at such a temp., *e. g.*,  $40^\circ$ , that practically all the steam and tar are condensed but not the producer gas and the  $\text{NH}_3$ , which are passed through a tar separator to remove final traces of tar. The  $\text{NH}_3$  is then converted into any desired salt by passage through an acid, and the gas is left in a pure condition. Any  $\text{NH}_3$  which is contained in the condensate from the reflux condenser is volatilized by any known method. Two or more condensers in series or parallel may be used, and free spaces in which the gases and vapors are stated to mix may be arranged between the tube plates of adjacent condensers. The air blast for the producer may be heated by the  $\text{H}_2\text{O}$  from the condensers, and in one form of heating and satg. this blast with moisture, the blast is passed between the two tubes forming the condenser, and the  $\text{H}_2\text{O}$  is used in the form of a film or spray.

**Peat.** C. BOUILLON. Brit. 118,993, Mar. 15, 1918. Vegetable fibers are sepd. from peat and graded, and the peat is freed from foreign matters and brought to a pure and dry state by a continuous process. The peat, as it comes from the bog, is fed through a hopper into an app. by which it is rolled, molded, torn, or crumbled, and then it is carried by a draining conveyer to a tank; the conveyer is preferably given a shaking motion. In the tank is a soln. of a salt capable of coagulating blood, *e. g.*,  $\text{CaCl}_2$  or  $\text{Fe}_2\text{Cl}_6$ , and the peat is treated with this during its passage through the tank by the action of a rotary conveyer. The peat and soln. pass, by the aid of a jet of compressed air, along a pipe into a rotary sieve, which is a wire gauze cylinder secured to hoops supported by rollers above a trough. The sieve retains the fibers which are discharged into a launder, the discharge being assisted by jets of  $\text{H}_2\text{O}$  from pipes. Two or more sieves may be used in succession to effect a grading of the fibers. Earth, sand, and other foreign matters are removed from the peat by running the soln. and peat through a settling tank which may have an agitating pump and partitions dividing the tank into compartments, which can be separately emptied. The peat is air-dried, washed to remove the chloride, and dried in a drying room.

**Coke product of low density.** H. RODMAN. U. S. 1,283,310, Oct. 29. Coal or similar coking material is formed into pellets or fragments and heated to a coking temp. to produce a material which is suitable for filling reaction towers or for use as a filtering material.

**Heating coke-ovens.** R. GEIPERT. U. S. 1,281,775, Oct. 15. In heating coke-ovens, alternately burning illuminating gas and producer gas, illuminating gas is burned within a gas producer containing a column of fuel maintained in a state of incandescence by the heat generated by the burning illuminating gas, combustion products are passed through the incandescent fuel and the combustible gases thus formed are burned in the coke-oven.

**Coking pitch.** R. A. LEE. U. S. 1,283,229, Oct. 29. Pitch or similar material is heated under a pressure of several atm. to a temp. above  $315^{\circ}$  and the pressure is then reduced by causing the vapors and gases to expand in a confined space under atm. pressure while still heated. Portions of the material, thus coked, are sepd. from uncoked material.

## 22. PETROLEUM, ASPHALT AND WOOD PRODUCTS.

**Production and consumption of crude petroleum and other mineral oils.** 65th Congress, 2nd Session, Senate, *Document* 280, 16 pp.(1918).—A letter from Director Van H. Manning of the Bur. of Mines to the President of the Senate containing statistical information.

E. J. C.

**Action of aluminium chloride on petroleum.** AMÉ PICTET AND I. LĘCZYŃSKA. *Arch. sci. phys. nat.* 44, 400-1(1917).—When an upper fraction of petroleum distillates such as kerosene, lubricating oil or paraffin, is slowly heated with a small quantity (about 10%) of  $AlCl_3$ , the salt dissolves, imparting a dark brown to the soln. If this brown liquid is then submitted to fractional distn. the fraction between  $40^{\circ}$  and  $140^{\circ}$  possesses all the properties of natural petroleum benzine and may serve the same purposes. The nature of artificial benzine obtained varies with the nature and origin of the initial product; the kerosene oil of Galicia furnishes 50% of its weight, that of Bakau 40, lubricating oil of Bakau 31, Galician paraffin 35, etc. If, after the first fraction is sepd., the distn. is carried to  $400^{\circ}$ , products of more or less weight are obtained and there remains finally a black viscous residue which, after the  $AlCl_3$  is removed by aq. lixiviation, is similar to asphalt. The quantity of this residue varies from 11 to 56% by wt. of the original material, depending on the origin of the petroleum. The authors studied particularly the benzine and the solid residue obtained from the lubricating oil of Bakau (d. 0.907, upper b. p.  $300^{\circ}$ ). The benzine contains a mixt. of 35% of satd. hydrocarbons of the fatty series ( $C_{14}H_{30}$  and  $C_{16}H_{34}$ ) and 65% of satd. cyclic hydrocarbons ( $C_7H_{14}$  and  $C_8H_{18}$ ). Its calorific power is greater than that of natural benzine obtained by simple distn. of crude petroleum from the Caucasian region (11,386 cal. instead of 11,200), due to the fact that natural benzine contains only  $C_nH_{2n}$  hydrocarbons, while about  $\frac{1}{3}$  of artificial benzine consists of aliphatic hydrocarbons ( $C_nH_{2n+2}$ ). The formation of these last under the influence of  $AlCl_3$  is probably due to a sepn. of open side chains which are attached to satd. naphthene nuclei. These chains entrain with them hydrogen atoms from the nuclei with a consequence that the nuclei become unsatd. aromatic hydrocarbons. The unsatd. compds. thus formed have a great tendency to polymerize and it is this polymerization which gives rise to the solid residue so closely resembling asphalt.

J. H. YOUNG.

**Utilization of Italian products for the production of benzene.** II. A. G. RODANO. Rome. *Ann. chim. applicata* 10, 23-6(1918).—R. analyzed a new oil occurring in

Pavia. It was a pale pink liquid with bluish fluorescence, insol. in aniline, and having a characteristic mineral-oil odor, quite different from the odor of ordinary petroleum. It showed a neutral reaction to turnsole paper,  $d_{15}$  0.9132; Engler viscosity at 20° 1.77; flash point (Pensky-Martens) 80°; calorific power 10600 cal.; total S 0.22%. It began to distil at 180° with partial decompn. and development of vapors. The fractions distilling at 180–250°, 250–80, 280–310, 310–60, 360–70°, and residue at 370° were resp. 26, 26, 18, 18, 6, 6 cc. and had resp.  $d_{15}$  0.8826, 0.967, 0.9281, 0.949, 0.954, 1.006. The residue was black, dense and of the consistency of vaseline. It is evident from the high densities above that the oil does not contain either light benzine or kerosene adaptable to illuminating purposes. It is not suitable for lubrication because of its low viscosity and flash point. It would find its best use as a combustible. With the idea of finding a higher value for the oil, L. subjected it to cracking expts. (cf. C. A. 11, 3420). From 500 cc. of the crude petroleum were obtained 125 l. gas and 150 cc. of a black, tar-like liquid sol. in aniline (unlike the crude oil) and having a strong aromatic odor. The 150 cc. of this tar gave, on fractional distn., between 75 and 170°, 70 cc. of a limpid oil, slightly yellowish, of  $C_6H_6$  odor, and  $d_{15}$  0.872. This latter fraction, on new distn. up to 122°, gave 45 cc. of oil of  $d_{15}$  0.866, that could be completely nitrated. The nitrated product was insol. in  $H_2O$ , had an odor of nitrobenzene, and when distd. in a current of  $H_2O$  vapor yielded a straw-yellow liquid of bitter almond odor, b. 208–25°,  $d_{15}$  1.1833, indicating a mixt. of nitrobenzene and *o*-nitrotoluene, the latter in excess. The gaseous product obtained from decompn. of the crude oil was combustible, gave a luminous flame, and had an odor resembling that of acetylene. In all probability it was rich in aromatic hydrocarbons, recoverable by passing through heavy tar-oil. The decompn. of 100 parts of the crude oil yielded 25 l. combustible gas, 9 cc. oils distg. up to 122°, 5 cc. oils distg. between 122 and 170° and 16 cc. residual tar. The yield of benzene-toluene from the crude oil was about 12 times greater than that from an equal wt. of coal, not including the aromatic hydrocarbons recoverable from the gases of decompn.; considerable quantities of higher homologs (xylene, etc.) are no doubt present. R., for a further study, sepd. the crude oil into 2 fractions by ordinary distn., one below and the other above 280°. The latter fraction was a reddish brown liquid, amounting to 48% by wt.,  $d_{15}$  0.942, Engler viscosity at 20° = 5.55. Properly treated, it could be used as a good lubricant. R. subjected the lower fraction (distillate up to 280°) to "cracking," and obtained combustible gas and a tar with aromatic odor which yielded 4.78% benzene-toluene, based upon the crude oil.

ROBERT S. POSMONTIER.

**Asphalt,** related bitumens, and bituminous rock in 1917. JOHN D. NORTROP. U. S. Geol. Survey, *Mineral Resources of U. S., 1917*, Part II, 232–51 (Preprint No. 18, published Oct. 22, 1918); cf. C. A. 12, 93.

**Utilization of elm.** W. D. BRUSH. U. S. Dept. Agr., *Bull.* No. 683, 43 pp. (1918). —The classified uses of elm in different wood-using industries are given. J. J. S.

**Petroleum in Japan (CLEMENTS) 8.** Salt Creek oil field, Wyoming (WEGEMANN) 8. Dehydrating emulsions (petroleum and water) (U. S. pat. 1,281,952) 18.

**ABRAHAM, HERBERT:** *Asphalts and Allied Substances, their Occurrence, Modes of Production, Uses in the Arts and Methods of Testing.* New York: D. Van Nostrand Co. 606 pp.

**Separating lighter from heavier hydrocarbons by distillation.** F. A. HOWARD. U. S. 1,284,687, Nov. 12. In sepg. gasoline components from kerosene hydrocarbons,

or sepg. similarly differing hydrocarbons from each other, about equal vols. of the hydrocarbons and of cold  $H_2O$  are placed in a still and the liquids are heated therein so that the temp. of the vaporized contents of the still will not exceed about  $98^\circ$ , to distill off the lighter hydrocarbons.

**Removing paraffin or similar impregnating material from paper.** W. O. GAYNOR. U. S. 1,284,647, Nov. 12. Paraffin present as coating or impregnating material in paper is removed from the paper by immersing in gasoline or other liquid with which the impregnating material is freely miscible only when fused and the liquid surrounding the paper is heated to a temp. sufficiently high to fuse the impregnating material and to cause the convection currents to agitate the paper and diffuse the impregnating material throughout the liquid. The liquid and fused material are then drawn off.

**Gasoline.** J. B. WEIR. U. S., 1,282,338, Oct. 22. Gasoline is extd. from natural gas by compression and cooling, partially denuded gas being subjected to an absorption process. The products thus derived are blended and their vapor tension is reduced by driving off a portion of the more volatile constituents to obtain the finished product. A portion of these volatile constituents is absorbed in a hydrocarbon liquid heavier than gasoline and this product is used as the absorbent for the first mentioned absorption step.

**Distilling oils.** H. H. MANDLE. Brit. 119,284, Sept. 27, 1917. Hydrocarbon oils of a relatively low b. p., such as gasoline, benzene, toluene, etc., obtained from heavier oils of a high b. p. by mixing the heavy oil in predetd. proportions with  $H_2O$ , spraying the mixt. into a heating chamber or tubes heated to a temp. of from  $250$  to  $675^\circ$ , and subjecting the mixt. to the action of a catalytic agent consisting of an alloy of Ni, Cr and steel placed at the outlet end of the chamber or tubes, the mixt. being then passed through an oil-cooled primary condenser for removing the uncracked oils, and a water-cooled secondary condenser for condensing the hydrocarbons of lower b. p. The alloy may be in the form of woven wire or may be included in the compn. of the walls of the cracking tubes; or a stirrer or scraper may be made of the alloy. The pressure in the heating chamber or tubes may vary from atm. to 600 lb. per sq. in. A suitable app. is specified.

**Cracking oils; burners.** A. B. ADAMS. Brit. 119,485, July 5, 1917. Hydrocarbon oils are cracked for the production of low-boiling hydrocarbons, gas, etc., by mixing them with steam, passing the mixt. through a cracking chamber, and then, at the exit of the cracking chamber, bringing the products into contact with a finely attenuated mass of catalytic metal. A burner supplied with a mixt. of oil and steam also is described.

**Distilling and cracking oils.** D. T. DAY and R. B. DAY. Brit. 119,440, Nov. 16, 1917. Hydrocarbon oils are vaporized by causing hot products of combustion free from O to bubble through them. The process is used for removing gasoline from oils that are subsequently to be cracked by spraying into hot products of combustion under pressure as described in 113,264. Hot gases formed by combustion in a suitable chamber are led by a conduit into a cracking chamber into which oil is sprayed by a nozzle. The hot gases, together with the products formed by cracking at a temp. of at least  $360^\circ$ , are led to a perforated pipe in the base of the vaporizing chamber. The gases after bubbling through the oil are fed, together with the gasoline formed by vaporization, by a pipe to a fractionating tower maintained at least at  $190^\circ$ . The low-boiling hydrocarbons that escape condensation are led by a pipe to a condenser. The crude oil under treatment enters the fractionating tower by a pipe and trickles downwards. The oil thus heated, together with products formed by condensation, flows through a pipe to the vaporizing chamber. The oil after it has been freed from gasoline in the vaporizing chamber is pumped through a pipe to the spraying nozzle.

**Hydrocarbon oils.** D. T. DAY and R. B. DAY. Brit. 119,441, Nov. 16, 1917. Gasoline is purified by bubbling it through  $\text{H}_2\text{SO}_4$ ,  $\text{H}_2\text{O}$ , and  $\text{NaOH}$  in succession. The operation is effected in a series of washing app. containing the reagents, the gasoline being admitted by means of pipes fitted at their lower ends with spray devices. The gasoline rises to the top and flows away by a pipe. The app. is used in combination with the plant for cracking oils by spraying into hot products of combustion that is described in 113,264 (C. A. 12, 1347) and with the plant for pre-distg. the crude oil and fractionating and condensing the vapors that is described in 119,440. (See *supra*.)

**Hydrocarbon oils.** R. H. BROWNLEE. Can. 185,052, June 25, 1918. The yield of low boiling liquid products is increased by introducing steam adjacent the lower extremity of a vertically extending pipe system maintained at a temp. of over  $800^\circ\text{F}$ . and a pressure of over five atm., introducing the oil below the upper extremity of the system, continuously sepg. the heavier components from the lighter vaporized products and permitting a reflux of the former through the system so that the heavier components sepg. at any point undergo a further treatment in the presence of a lesser concn. of the lighter products than of the point of their sepn.

**Hydrocarbon extraction.** V. Z. READ. Can. 185,181, June 25, 1918. Shale or coal is submitted to destructive distn. in one chamber, the distillate is passed into a second chamber containing similar shale or coal to dissolve material from the shale and the solvent and extracted matter are recovered.

**Liquid fuel.** T. PAYNE. Brit. 119,066, Sept. 6, 1917. A fuel analogous to gasoline is obtained by subjecting hydrocarbon oils derived from petroleum, asphalt, bitumen, resin, bituminous shale, etc., to a treatment consisting in lowering the temp. and increasing the pressure of the liquid in successive stages and at each stage introducing a fuel gas, the product being thereafter restored to substantially atm. pressure and temp. E. g., kerosene may be reduced to about  $32^\circ\text{F}$ . under 6 atm. pressure and about 5 vols. of coal gas forced in; the pressure may then be increased to 8 atm. and the temp. lowered to about  $0^\circ\text{F}$ . and about 8 vols. of Pintsch gas introduced; or coal gas, acetylene, and H may be successively introduced into kerosene at temps. and pressures ranging to  $-32^\circ\text{F}$ . and 15 atm. The product is preferably kept under a pressure slightly above atm.

**Oil-still.** O. C. SWAN. U. S. 1,283,945, Nov. 12. The still is especially adapted for reclaiming waste oil from internal-combustion engines.

**Retort for recovering values from oil-bearing shales, bitumens, and similar materials.** J. H. GALLOUPE. U. S. 1,283,723, Nov. 5.

**Apparatus and mode of operating for distilling petroleum oils.** E. A. JOHNSON and W. SNODGRASS. U. S. 1,283,202, Oct. 29.

**Apparatus for distilling oil from oil-shale or similar materials.** G. W. WALLACE. U. S. 1,283,000, Oct. 29. Suction pipes are connected to perforated take-off pipes placed within vertical retorts. U. S. 1,283,001 relates to a method of operating such an app. in which the material treated is placed in a vertical closed retort, externally heated, gases and vapors and liquids being drawn off under suction through a perforated pipe extending into the central part of the retort from the bottom of the latter.

**Diolefins.** G. MERSEREAU. U. S. 1,282,906, Oct. 29. Oil gas is heated to about  $700^\circ$  to produce a mixt. of hydrocarbons containing a considerable % of diolefins, cooled to remove residual oil and the diolefins are recovered from the mixt. thus obtained by scrubbing with wash oil at zero. The remaining gas may be reheated to produce a further quantity of diolefins.

**Apparatus and process for cracking petroleum oils.** M. J. TRUMBLE. U. S. 1,281,884, Oct. 15. Heavy petroleum oil is first forced through a heating coil heated

sufficiently to crack the oil, at such a rate and under such pressure as to form a foam within the coil without danger of unduly burning the oil. Light vapors are removed from the stream of oil and the residual oil, after removal of the vapors, is passed through the heating coil to form more foam. The process is thus carried out in a cycle; small amts. of fresh oil are added as required and portions of condensed vapors and heavy oil and solid materials are withdrawn in compensating ratios.

**Apparatus for extracting and refining oils.** E. T. ERICKSON. U. S. 1,281,320, Oct. 15. The app. is arranged to treat oil-bearing shale in narrow metal retorts. Perforated pipes extend within the retorts and serve for the exit of vapors and gases from the retorts.

**Treating used lubricants.** J. O. HANDY. U. S. 1,281,354, Oct. 15. Used lubricants (such as those which have been employed for lubricating internal-combustion engines) are dissolved in gasoline or a similar hydrocarbon solvent, suspended solid matter is removed from the soln., the soln. is decolorized (e. g., by treatment with bone-black or fuller's earth), treated successively with an alkali and acid, neutralized and washed and the solvent is distd. off. The product thus recovered is adapted for re-use. U. S. 1,281,355 relates to similar process, except that the treatment with acid is omitted.

---

### 23. CELLULOSE AND PAPER.

---

A. D. LITTLE.

**Cellulose and nitrocelluloses.** A. HERVÉ. *Mon. sci.* 8, 193-6(1918).—The stability of nitrocellulose is considerably affected by the value of the ratio  $H_2SO_4/HNO_3$ . By varying this ratio from 1:1 up to 5:1 the amt. of fixed  $H_2SO_4$  in the nitrocellulose increases from 0.0505 to 1.860%. The stability (Abel test) of the nitrocellulose after boiling 8 hr. with  $H_2O$  varied inversely with the amt. of  $H_2SO_4$  in the nitrating mixt. Nitrocellulose can be stabilized by boiling with  $H_2SO_4$  and  $HCl$  (0.2 to 1.0%), followed by boiling with a dil. alkali. The sapon. of the impurities is, however, slow. More satisfactory results are obtained by boiling the nitrocellulose with 0.1 to 1% of its wt. of  $MgCl_2$  for 12 hr. Nitrocellulose so stabilized with  $MgCl_2$  gave a test of over 60 min. (Abel).

R. B. ROG.

**Lignin.** I. Lignosulfonic acid (HÖNIG, SPITZER) 10. Dyes from waste sulfite liquor (U. S. pat. 1,283,296) 25.

---

**STRACHAN, JAMES:** *The Recovery and Re-Manufacturing of Waste Paper.* Aberdeen: The Albany Press. 158 pp. 12s. 6d.

---

**Method for producing the zinc chloride solution of cellulose.** W. OGAWA. *Can.* 187,349, Nov. 5, 1918.  $ZnCl_2$  soln. is heated to about  $100^\circ$  in the presence of an excess of  $ZnCl_2$  sufficient to sat. the soln. at the temp. attained, and cellulose is added. It dissolves in this soln. in a very short time, producing a practically colorless soln. which gives a strong film or thread after coagulation.

**Digester and associated apparatus for the manufacture of cellulose.** E. SCHAUFFELBERGER. U. S. 1,282,635, Oct. 22. The app. is especially adapted for the manuf. of pulp from wood, bamboo or esparto.

**Alcohol and other products from waste sulfite liquor.** R. H. MCKEE. U. S. 1,284,739, Nov. 12. Waste sulfite liquor is purified by treating it with  $BaCO_3$  under oxidizing conditions, thus forming a sludge containing  $BaSO_4$  and, after sepg. the sludge,

the purified liquor is fermented and distd. to obtain alc. The sludge is furnaced under reducing conditions to obtain BaS and the latter is then converted into BaCO<sub>3</sub> by treating it under pressure with CO<sub>2</sub> from the fermentation vats.

Alcohol from waste sulfite liquor. R. H. McKEE. U. S. 1,284,740, Nov. 12. Waste sulfite liquor is subjected to the action of BaS under oxidizing conditions, forming a sludge containing BaSO<sub>4</sub> and eliminating injurious S compds. and the sludge is furnaced under reducing conditions to regenerate the BaS. The purified liquor is fermented with yeast.

Mixed ketones for use as solvents. H. HIBBERT. U. S. 1,283,183, Oct. 29. A mixt. suitable for use as a solvent for nitrates and other esters of cellulose is made by fermenting distillery slop so as to obtain a product rich in butyric acid, converting the acids of this mixt. in vapor form into the corresponding ketones by catalysis with an oxide of Th, Ce, Zr or U and then hydrogenating and acetylating the product. The mixt. formed contains a large proportion of butyrene, b. 110-60° (the greater portion b. 135-45°) and has a sp. gr. of about 0.8. It may be distd. with steam at a temp. somewhat below 100°.

Sulfite wood pulp. V. DREWSEN. U. S. 1,283,114, Oct. 29. Sulfite wood pulp from spruce, hemlock, fir or balsam wood is refined to render it suitable for the manuf. of nitrocellulose, by bleaching for 4-8 hrs. with an aq. soln. of bleaching powder, washing, and then boiling under pressure for several hrs. with an aq. NaOH soln. to dissolve and remove the oxy- and hydrocellulose, washing, and again bleaching with bleaching powder while keeping its soly. in KOH below 7%.

Refining wood pulp. V. DREWSEN. U. S. 1,283,113, Oct. 29. Pine, spruce or similar soda or sulfate process wood pulp is refined to render it suitable for the manuf. of nitrocellulose or other uses by bleaching for several hrs. with an aq. soln. containing 2-8% Cl calcd. on the dry wt. of the pulp and then treating the yellow partially bleached product thus obtained with a boiling Na<sub>2</sub>CO<sub>3</sub> soln. under pressure for several hrs. The soly. of the pulp in KOH is reduced to less than 7%.

## 24. EXPLOSIVES AND EXPLOSIONS.

---

CHARLES E. MUNROE.

Coating paper. C. M. GAGE, JR. U. S. 1,282,564, Oct. 22. A coating material such as a clay mixt. is applied to the surface of paper by means of rolls which force the material into the pores of the paper, the material is partly dried by blasts of air, subjected to smoothing rolls and then given a second or finishing coating.

Cellulose and nitrocellulose (HERVÉ) 23. Pathology and treatment of trinitrotoluene poisoning (FOULERTON) 11H. Electrically heated ovens (ANON.) 4.

BIEDERMANN, R.: *Die Sprengstoffe, ihre chemie und Technologie*. Leipzig: B. G. Teubner. 124 pp. Mk. 1.50.

COLVER, E. DE W. S.: *High Explosives*. New York: D. Van Nostrand Co. 776 pp. \$20.00.

Explosive. C. E. GRIFFING. U. S. 1,282,413, Oct. 22. An explosive stated to be adapted for use as a gun powder is formed of KClO<sub>4</sub> 50, sugar 49, KMnO<sub>4</sub> 0.33, S 0.33 and talcum powder 0.33 part.

**Explosive.** P. E. HAYNES and H. E. THOMPSON. U. S. 1,282,229, Oct. 22. Carbonized balsa wood and liquid O or liquid ozone are mixed to form an explosive.

**Casting explosive charges for projectiles.** P. G. PARIS. U. S. 1,282,623, Oct. 22. The air is exhausted from a hermetically sealed mold provided with a riser and the charge-forming material is then siphoned from a supply of molten material into the mold and riser and while the material in the mold is solidifying the portion in the riser is maintained in molten condition. Air is then admitted to the riser and excess molten material is drained off.

**Nitrating organic compounds.** L. W. ANDREWS. U. S. 1,283,617, Nov. 5. An acid amide, preferably urea, is added (in the proportion of about 1%) to the nitration mixt. used for making nitroglycerin, TNT, picric acid or other org. compds., to diminish risk from rise in temp. and to restrict undesired oxidation of the material undergoing nitration.

**Matches.** L. V. ARONSON. Can. 187,356, Nov. 12, 1918. The head of the match is ignitable by friction. It contains  $\text{KClO}_3$  one part.  $\text{KNO}_3$  two parts, lamp black and P 60 parts each and dextrin 20 parts, all covered with a suitable waterproof compn. This match is found very satisfactory for outdoor use.

## 25. DYES AND TEXTILE CHEMISTRY.

L. A. OLNEY.

**Fastness of colors to light.** G. A. HALCY. *J. Soc. Dyers Colourists* 34, 201-2 (1918).—Referring to the method of standardizing fastness of colors of Robson (*C. A.* 12, 2250), H. draws attention to several deficiencies and errors. The method of judging results as soon as first sign of fading appears is open to criticism. No important details are given of comparing different colors in the same depth of shade. By R.'s method Thionol Corinth G. X. appears to be faster than Thionol Brown O., while repeated comparative tests made by H. show the opposite to be true. It is doubtful that Congo Corinth possesses 3 times the fastness of Congo Rubine, and that certain sulfur browns are equal in fastness to aniline black. The numerical method of recording color fastness possesses disadvantages in the lower scale, for a color fading in two days would be recorded as four times as fast as one fading in four hours, whereas both should be placed in the same category. The method of comparing a color with other colors of known fastness is the best; the method recommended by the German Fastness Commission using 5 or 6 graded standards of each color would be highly desirable.

L. A. OLNEY.

**The production of dyeings fast to light.** K. GEBHARD. *J. Soc. Dyers Colourists* 34, 74-6 (1918).—There are 3 methods differing in principal by which the fading of dyes can be prevented. (1) Dissociation of the equil.  $\text{G}^1 - \text{O}^1 + \text{H}^+ + \text{OH}^- \rightleftharpoons \text{H.O.OO.H} \rightleftharpoons \text{OH}^+ + \text{OOH}^-$  in disfavor of  $\text{OOH}^-$ . Equil. established in darkness will be altered at once by the influence of light. The equil. is influenced by all substances in the system. When it is ascertained what kind of influence takes place under the action of light the equil. can be established by a suitable concn. of substance and when this is not possible new substances may be introduced into the system. With wool and fibers not sensitive to  $\text{H}^+$  and  $\text{OH}^+$  ions favorable results can be obtained if to begin with the equil. is altered in disfavor of the  $\text{OOH}^-$  ions. This condition is produced by increasing the H-ion concn. in aq. solns. of acid dyes. With cotton, however, conditions are different, as it reacts easily with  $\text{H}^+$  and  $\text{OH}^+$  ions. Only if the reaction between the cotton and the  $+$  H and  $\text{OH}^+$  can be prevented by a suitable treatment will there be a prospect of producing dyeings fast to light. (2) Pre-

venting or rendering difficult the reaction between the dyestuff and the perhydroxyl ions. It is possible that substances exist which would prevent reaction between the dyestuff and perhydroxyl ions, and between fiber and  $\text{OH}^+$  but no such expts. have been recorded. The facility of reaction between dyestuff and  $\text{OOH}^-$  may be decreased by converting the dyestuff into the least reactive state, *i. e.*, making it difficultly sol. This is the most common method, as illustrated by after-treatment with  $\text{CuSO}_4$ . The reaction between the dyestuff and perhydroxyl ions can also be prevented by directing the perhydroxyl ions into other channels. Small quantities of certain substances, *e. g.*, cerium sulfate or citrate of lime, are sufficient to eliminate continually the detrimental perhydroxyl oxygen atom. (3) Transformation of the dyestuff peroxides into more stable compds. If the formation of dyestuff peroxides cannot be prevented or if for other reasons none of the previous methods can be employed, use can be made of the important fact that dyestuff peroxides still possess the dyestuff character. Such dyestuffs may be used as from their constitution or on account of their combination with certain substances possess the property of splitting off the elements of water from the labile dyestuff, the "peroxyhydrates" thus changing with more stable dyestuff peroxides. When a dyestuff peroxide possesses dyestuff character there is the question whether it may not be possible to replace the peroxide oxygen in the dyestuff with some other radical which may make it more stable. The fiber under some circumstances may serve as such a radical. (4) Fastness to light is also increased by keeping back unfavorable influences of moisture.

L. A. OLNEY.

**Consolidating American dyestuff exports.** L. W. SCHMIDT. *Color Trade J.* 3, 385-7(1918).—It will be necessary for American dyestuff manufacturers to keep in close touch with Europe, for many foreign countries may be more readily reached through London, Lyons and Paris, than directly.

L. A. OLNEY.

**Progress in intermediates.** EDITORIAL. *Color Trade J.* 3, 388(1918).—More research and effort are required in the manuf. of intermediates than in the manuf. of the dyestuffs themselves. About 85% of money invested in dyestuff plant is absorbed in manuf. of intermediates. Great care must be taken as to their purity and freedom from other intermediates as this greatly influences the purity of the dyes produced from them. Chem. mfrs. must be prepd. to devote large sums of money to intensive and thorough research in the practical manuf. of these products. Since low cost often depends in the manuf. on large scale, it would be foolish for every dyestuff factory to manuf. all of its intermediates.

L. A. OLNEY.

**Safeguarding the dyestuff industry.** J. MERRITT MATHEWS. *Color Trade J.* 3, 381-4(1918).—Discussion of post war conditions of importance to dyestuff industry in which the following items are given prominence. The advantage of the import license system as operated in England, the necessity of a higher tariff, the advisability of cooperative control so as to evolve a unified plan of manuf. and development of research and technic are given.

L. A. OLNEY.

**Indigenous fibrous plants of Victoria.** J. W. AUDAS. *J. Dept. Agr. Victoria* 16, 600-9(1918).—A list is given of the flora well adapted to the manuf. of fibers occurring in Victoria, together with a description, location, and extent of occurrence of each variety. Cf. *C. A.* 12, 1804.

J. J. SKINNER.

WHITTAKER, C. M.: **Dyeing with Coal-Tar Dyestuffs.** London: Baillière, Tindall and Cox. 214 pp. 7s. 6d.

**Dyeing apparatus.** A. RUDLER. *U. S.* 1,282,633, Oct. 22.

**The production of dyes.** W. W. COE. Can. 187,675, Nov. 26, 1918. A dye containing extd. coloring matter of plant substances of the banana class is obtained by treating the banana fruit substance with a hydrolyzing agent in the presence of a compd. of one of the heavier metals.

**Azo dyes.** H. LEVINSTEIN. U. S. 1,283,231, Oct. 29. *p*-Aminoacetanilide 153 parts is diazotized and coupled in an alk. soln. with 200 parts of  $\beta$ -hydroxynaphthoic acid. The dye formed is sepd. by filtration and then hydrolyzed by heating to 90° with a 5% soln. of NaOH. Fast blue shades are produced by the dye when applied to chrome-mordanted wool with the addition of a little acid. Instead of *p*-aminoacetanilide, similar benzene derivs. containing halogen, alkoxy, sulfo or alkyl groups as substituents for H may be employed, yielding similar dyes.

**Azo dyes.** E. ANDERWERT, H. FRITZSCHE and H. SCHOBEL. U. S. 1,282,354, Oct. 22. Diazotized 4,2,1-nitroaminophenol, combined with *m*-aminobenzoyl-2,5,7-aminonaphtholsulfonic acid, produces a dye which dyes cotton dull roseate shades. Diazotized on the fiber with  $\beta$ -naphthol the tints become more yellowish. Diazotized nitroaminophenol when combined with the ureide of naphtholsulfonic acid,  $(\text{SO}_2\text{H}(\text{OH})\text{C}_6\text{H}_4\text{NH})_2\text{CO}$ , yields a dye which forms a violet soln. with  $\text{H}_2\text{O}$  and dyes cotton blue-violet shades which become clear chestnut-brown when developed on the fiber with *p*-nitrodiazobenzene. If *o*-aminophenolsulfonic acid be used as starting material instead of nitroaminophenol, in the last previously mentioned combination, a dye is obtained which produces scarlet-red on cotton. Diazoacylphenol derivs. may be used to produce similar dyes. The dyes thus formed are suitable for dyeing cotton, wool, silk, straw, wood, paper and mixed goods and also for the production of lakes.

**Azo dyes.** E. ANDERWERT, H. FRITZSCHE and H. SCHOBEL. U. S. 1,282,355, Oct. 22. Tetrazotized benzidine is combined with salicylic acid and the intermediate product thus formed, after acidulating with HCl until it shows a weakly acid reaction with Kongo, is combined with 2,5,7-aminonaphtholsulfonic acid, and then with the diazotized deriv. of *o*-aminosulfosalicylic acid. The trisazo dye thus formed dyes cotton brown. The dye obtained from benzidine, 2,5,7-aminonaphtholsulfonic acid and *o*-aminophenolsulfonic acid dyes cotton heliotrope tints. The trisazo dye from benzidine, 1,8,3,6-aminonaphtholdisulfonic acid, 1,8,2,4-aminonaphtholdisulfonic acid and 4,2,1-nitroaminophenol dyes cotton gray-blue tints. The following starting materials may also be used to produce similar dyes: tolidine, dianisidine, diaminostilbenedisulfonic acid, diaminodiphenyl ether, diaminodiphenylamine, aminobenzoyl-*m*-phenylenediamine, azoxyaniline, azoxytoluidine, aminodiphenylurea, diaminodiphenylthiourea.

**Azo dyes.** E. ANDERWERT, H. FRITZSCHE and H. SCHOBEL. U. S. 1,282,356, Oct. 22. Azo dyes suitable for use on cotton, wool, silk, mixed goods, straw, and other materials are produced by the combination of diazo derivs. of an *o*-aminophenol or *o*-aminonaphthol compd. with a second component capable of combining with two different diazo compds., e. g., 2,5,7-aminonaphtholsulfonic acid, 2,5,1,7- or 1,8,3,6- or 1,8,4,6-aminonaphtholdisulfonic acid, 1,8,5-aminonaphtholsulfonic acid, resorcinol, *m*-aminophenol, *m*-phenylenediamine, 2,7-dihydroxynaphthalene or an aminonaphthol and then combining this dye, as an intermediate product, with a tetrazotized deriv. of dianisidine, benzidine, tolidine, diaminostilbenedisulfonic acid, diaminodiphenyl ether, diaminodiphenylamine, aminobenzoyl-*m*-phenylenediamine, azoxyaniline, azoxytoluidine, diaminodiphenylurea or diaminodiphenylthiourea. The dye formed from *o*-aminophenol, dianisidine, and 1,4-naphtholsulfonic acid dyes unmordanted cotton dull blue. The dye from *o*-aminophenolsulfonic acid, benzidine and 2,5,7-aminonaphtholsulfonic acid dyes unmordanted cotton violet. Diazotized acylphenol derivs. also may be used as components in making similar dyes.

**After-chromable azo dye.** SOC. ANON. POUR L'IND. CHIM. A BÂLE. Swiss 77,803, June 1, 1918. In the manuf. of an after-chromable azo dye, the monoazo dye obtained by coupling 1-diazo-2-hydroxynaphthalene-4-sulfonic acid with 1-hydroxy-3-amino-4-methylbenzene in alk. soln., is further diazotized, and the resulting diazoazo compd. is coupled with resorcinol. The dye colors wool from acid bath in blue-black shades after-chroming to a fast green-black.

**After-chromable azo dyes.** SOC. ANON. POUR L'IND. CHIM. A BÂLE. Swiss 78,020, 78,021, 78,022, all of June 17, 1918. Addition to 77,803. (See *supra*.) The monoazo dye obtained by coupling nitro-1-diazo-2-hydroxynaphthalene-4-sulfonic acid with 1-hydroxy-3-amino-4-methylbenzene in alk. soln. is further diazotized, and the product coupled with resorcinol. The dye colors wool from acid bath in violet-black shades, after-chroming to a fast greenish black. The monoazo dye obtained by coupling 1-diazo-2-hydroxynaphthalene-4-sulfonic acid with 1-hydroxy-3-aminobenzene, in alk. soln., is further diazotized, and the resulting diazo compd. is coupled with resorcinol. The dye colors wool, in acid bath, in blue-black shades, after-chromable to a fast green-black. The monoazo dye obtained by coupling 1-diazo-2-hydroxynaphthalene-4-sulfonic acid with 1-hydroxy-3-aminobenzene, in alk. soln., is further diazotized, and the resulting diazo compd. is coupled with 1-hydroxy-3-aminobenzene. The product dyes wool, in acid bath, in black-violet shades, after-chromable to a fast greenish black.

**Acid dye containing chromium.** SOC. ANON. POUR L'IND. CHIM. A BÂLE. Swiss 77,662, May 16, 1918. The reactive azo dye from diazotized 1-amino-2-hydroxynaphthalene-4-sulfonic acid and  $\beta$ -naphthol, is treated with Cr oxide or its salts until the reaction is complete. The Cr is intimately combined, and does not ppt. from its aq. soln. by means of  $\text{Na}_2\text{CO}_3$ , NaOH, or  $\text{NH}_4\text{OH}$ . The product dyes animal fibers from acid bath in fast blue shades.

**Acid dyes with copper in fast combination.** SOC. ANON. POUR L'IND. CHIM. A BÂLE. Swiss 77,720-30, May 16, 1918. Addition to 76,560. The dyes obtained as specified below are treated with  $\text{CuSO}_4$  to obtain products from which the combined Cu is not pptd. from aq. soln. by  $\text{Na}_2\text{CO}_3$ , NaOH, or  $\text{NH}_4\text{OH}$ . The products are sol. in  $\text{H}_2\text{O}$  and dye animal fibers from acid bath as stated, the shades being fast to washing and light. Dark blue shades are produced by the Cu compd. of the azo dye from diazotized 4-chloro-2-amino-1-hydroxybenzene and benzylacetic-*o*-carboxylic acid. Brown-orange shades are produced by the Cu compd. of the azo dye from diazotized 4-nitro-2-amino-1-hydroxybenzene and 1-(2'-hydroxy-5'-sulfophenyl)-3-methyl-5-pyrazolone. Blue shades are obtained by the Cu compd. of the azo dye from diazotized 4-sulfo-2-amino-1-hydroxybenzene-6-carboxylic acid and benzolacetic-*o*-carboxylic acid. Reddish brown shades are produced by the Cu compd. of the azo dye from diazotized 2-amino-1-hydroxybenzene-4-sulfonic acid and diketohydrindene. Bordeaux shades are produced by the Cu compd. of the azo dye from diazotized 1-amino-2-naphthol-4-sulfonic acid and *peri*-naphthindandione. Red-violet shades are produced by the Cu compd. of the azo dye from diazotized 2-amino-1-hydroxybenzene-4-sulfonic acid and 3-hydroxy-1-thionaphthene. Violet-blue shades are produced by the Cu compd. of the azo dye from diazotized 1-amino-2-naphthol-4-sulfonic acid and 3-hydroxy-1-thionaphthene. Red shades are obtained from the Cu compd. of the azo dye from the diazotized 6-nitro-2-amino-1-hydroxy-4-methylbenzene and 1-(3'-sulfo-4'-hydroxyphenyl)-3-methyl-5-pyrazolone. Brown-orange shades are obtained from the Cu compd. of the azo dye from diazotized 2-amino-1-hydroxybenzene-4-sulfonic acid and 1-(2'-hydroxy-5'-nitrophenyl)-3-methyl-5-pyrazolone. Brown-orange shades, after-chromable, are produced by the Cu compd. of the azo dye from diazotized 4-nitro-2-amino-1-hydroxybenzene and 1-(4'-hydroxy-5'-carboxyphenyl)-3-methyl-5-pyrazolone.

**Acid dyes with copper in fast combination.** SOC. ANON. POUR L'IND. CHIM. À BÂLE. Swiss 77,731-6, June 1, 1918. Additions to 76,560. The azo dyes obtained as specified below are treated with  $\text{CuSO}_4$ , to obtain products from which the combined Cu is not pptd. from aq. soln. by  $\text{Na}_2\text{CO}_3$ , NaOH, or  $\text{NH}_4\text{OH}$ . The products are sol. in  $\text{H}_2\text{O}$  and dye animal fibers from acid bath in the shades noted, which are fast to washing and light. The azo dye obtained from diazotized 1-amino-2-hydroxynaphthalene-4-sulfonic acid and 1-(4'-hydroxy-5'-carboxyphenyl)-3-methyl-5-pyrazolone yields upon treatment with  $\text{CuSO}_4$ , a dye giving garnet shades. Brick-red shades are obtained from the Cu compd. of the azo dye obtained from diazotized 2-amino-1-hydroxybenzene-4-sulfonic acid and 7-hydroxy-4-methyl-1,2-benzopyrone. Wine-red shades are produced by the Cu compd. of the azo dye from diazotized 4-chloro-2-amino-1-hydroxybenzene-6-sulfonic acid and 7-hydroxy-4-methyl-1,2-benzopyrone. Brick-red shades are obtained from the Cu compd. of the azo dye from diazotized 2-amino-1-hydroxybenzene-4-sulfonic acid and 7-hydroxy-4-carboxy-1,2-benzopyrone. Brick-red shades are produced by the Cu compd. of the azo dye from diazotized 4-sulfo-2-amino-1-hydroxybenzene-6-carboxylic acid and 7-hydroxy-4-carboxy-1,2-benzopyrone. Yellow-brown shades are produced by the Cu compd. of the azo dye from diazotized 2-amino-1-hydroxybenzene-4-sulfonic acid and the condensation product of 1,6-dihydroxynaphthalene with phthalic acid.

**Acid dyes containing chromium.** SOC. ANON. POUR L'IND. CHIM. À BÂLE. Swiss 77,737-52, June 1, 1918. Addition to 77,248 (C. A. 12, 2133). In the manuf. of acid dyes contg. Cr in fast mol. combination, i. e., not pptd. from aq. soln. by  $\text{Na}_2\text{CO}_3$ , NaOH, or  $\text{NH}_4\text{OH}$ , the dyes specified below are treated, with heating, with alkali chromate solns. Animal fibers are dyed from acid soln. in the specified shades, fast to light and milling. Yellowish green shades are produced by the Cr compd. of the azo dye from diazotized 4-sulfo-2-amino-1-hydroxybenzene-6-carboxylic acid and benzoyl-acetic-o-carboxylic acid. Blue shades are produced by the Cr compd. of the azo dye from diazotized 1-amino-2-hydroxynaphthalene-4-sulfonic acid and  $\beta$ -naphthol. Blue shades are produced by the Cr compd. of the azo dye from diazotized 1-amino-2-hydroxynaphthalene-4-sulfonic acid and  $\alpha$ -naphthol. Blue shades are produced by the Cr compd. of the azo dye from chloro-1-diazo-2-hydroxynaphthalene-4-sulfonic acid and  $\beta$ -naphthol. Blue shades are produced by the Cr compd. of the azo dye from chloro-1-diazo-2-hydroxynaphthalene-4-sulfonic acid and  $\alpha$ -naphthol. Blue shades are produced by the Cr compd. of the azo dye from bromo-1-diazo-2-hydroxynaphthalene-4-sulfonic acid and  $\beta$ -naphthol, or  $\alpha$ -naphthol. Violet-brown shades are produced by the Cr compd. of the azo dye from diazotized 1-amino-2-hydroxynaphthalene-4-sulfonic acid and *peri*-naphthindandione. Bluish red shades are produced by the Cr compd. of the azo dye from diazotized 1-amino-2-hydroxynaphthalene-4-sulfonic acid and 1-phenyl-3-methyl-5-pyrazolone. Red shades are produced by the Cr compd. of the azo dye from diazotized 1-amino-2-hydroxynaphthalene-4-sulfonic acid and 1-(3'-nitrophenyl)-3-methyl-5-pyrazolone. Violet shades are obtained with the Cr compd. of the azo dye from diazotized 2-amino-1-hydroxybenzene-4-sulfonic acid and  $\beta$ -naphthol. Violet shades are produced by the Cr compd. of the azo compd. from diazotized 2-amino-1-hydroxybenzene-4-sulfonic acid and 2-amino-5-hydroxynaphthalene-7-sulfonic acid. Reddish yellow shades are produced by the Cr compd. of the azo dye from diazotized 1-aminonaphthalene-4-sulfonic acid and salicylic acid. Red-violet shades are produced by the Cr compd. of the azo dye from diazotized 2-amino-1-hydroxybenzene-4-sulfonic acid (3'-carboxy-4'-hydroxyphenyl)amide and  $\beta$ -naphthol. Red-violet shades are produced by the Cr compd. of the azo dye from diazotized 2-amino-1-hydroxybenzene-4-sulfonic acid (3'-carboxyphenyl)amide and  $\beta$ -naphthol. Red shades are produced by the Cr compd. of the azo dye from diazotized 4-chloro-2-amino-1-hydroxybenzene-6-sulfonic acid and 1-phenyl-3-methyl-5-pyrazolone.

**Acid dyes with copper in fast combination.** SOC. ANON. POUR L'IND. CHIM. A BÂLE. Swiss 77,871-8, June 1, 1918. Addition to 76,560. The dyes obtained as specified below are treated with  $\text{CuSO}_4$  to obtain products from which the combined Cu is not pptd. from aq. soln. by  $\text{Na}_2\text{CO}_3$ ,  $\text{NaOH}$ , or  $\text{NH}_4\text{OH}$ . The products are sol. in  $\text{H}_2\text{O}$  and dye animal fibers from acid bath as stated, the shades being fast to washing and light. Brown-orange shades are produced by the Cu compd. of the hydrazone dye from 1 mol. of 1-hydroxy-2-hydrazinobenzene-4-sulfonic acid and 1 mol. dihydroxy tartaric acid. Brown-orange shades are produced by the Cu compd. of the hydrazone dye from 1 mol. phenylhydrazine, 1 mol. 1-hydroxy-2-hydrazinobenzene-4-sulfonic acid and 1 mol. dihydroxytartaric acid. Yellow-brown shades are obtained from the Cu compd. of the hydrazone dye from 2 mol. of 2-hydrazino-3-naphthol-6-sulfonic acid and 1 mol. of dihydroxytartaric acid. Cerise-red shades are obtained from the Cu compd. of the hydrazone dye from 1 mol. 1-hydroxy-2-hydrazinobenzene-4-sulfonic acid and 1 mol. 1,2,4-naphthoquinonesulfonic acid. After-chromable bordeaux-red shades are produced by the Cu compd. of the hydrazone dye from 1 mol. 1-hydroxy-2-hydrazinobenzene-4-sulfo-6-carboxylic acid and 1 mol. phenanthrenequinone. Deep gray shades are produced by the Cu compd. of the hydrazone dye from 1 mol. of 1-hydroxy-2-hydrazinobenzene-4-sulfonic acid and 1 mol. acenaphthenequinone. Red-brown shades are produced by the Cu compd. of the hydrazone dye from 2 mol. of 4-Cl-1-hydroxy-2-hydrazinobenzene and 1 mol. dihydroxytartaric acid. Dark brown shades are produced by the Cu compd. of the hydrazone dye from 1 mol. 1,2-naphthoquinone-4-sulfonic acid and 1 mol. 2-hydrazinobenzene-1-carboxylic acid.

**Disazo dyes.** A. E. GESSLER. U. S. 1,281,938, Oct. 15. Disazo dyes are produced by combining tetrazotized di-*p*-aminoditolyl with 2,6- or 2,7-naphtholsulfonic acid. The alkali metal salts and other metal salts of the dyes are insol. in  $\text{H}_2\text{O}$ , oils and usual org. solvents.

**Acid disazo dyes.** SOC. ANON. POUR L'IND. CHIM. A BÂLE. Swiss 78,180-78,205, July 1, 1918. Addition to 77,540 (C. A. 12, 2448). A series of disazo dyes is obtained by coupling the tetrazo compd. from 3,3'-diamino-4,4'-dimethyldiphenylmethane with 2 mols. of 1-hydroxynaphthalene-3-sulfonic acid, or with 2 mols. of 1-hydroxynaphthalene-5-sulfonic acid, or with 2 mols. of 2-hydroxynaphthalene-6-sulfonic acid, or with 2 mols. of 2-hydroxynaphthalene-8-sulfonic acid, or with 2 mols. of 1-hydroxynaphthalene-3,6-disulfonic acid, or with 2 mols. of 1-hydroxynaphthalene-3,8-disulfonic acid, or with 2 mols. of 1-hydroxynaphthalene-4,8-disulfonic acid, or with 2 mols. of 2-hydroxynaphthalene-3,6-disulfonic acid, or with 1 mol. of 1-hydroxynaphthalene-4-sulfonic acid and 1 mol. of 2-hydroxynaphthalene-6-sulfonic acid, or with 1 mol. of 2-hydroxynaphthalene-3,6-disulfonic acid and 1 mol. of  $\beta$ -naphthol, or with 1 mol. of 1-sulfophenyl-3-methyl-5-pyrazolone and 1 mol. of 1-hydroxynaphthalene-4-sulfonic acid, or with 1 mol. of 1-sulfophenyl-3-methyl-5-pyrazolone and 1 mol. of 2-hydroxynaphthalene-6-sulfonic acid, or with 1 mol. of 2-hydroxynaphthalene-3,6-disulfonic acid and 1 mol. acetoacetanilide, or with 1 mol. of 2-hydroxynaphthalene-3,6-disulfonic acid and 1 mol. of barbituric acid, or with 1 mol. of 2-hydroxynaphthalene-3,6-disulfonic acid and 1 mol. of 1-hydroxy-4-methylbenzene, or with 1 mol. of 1-hydroxynaphthalene-4,8-disulfonic acid and 1 mol. of acetoacetanilide. Another series of dyes is obtained by coupling the tetrazo compd. from 3,3'-diaminodiphenylmethane with 2 mols. of 1-hydroxynaphthalene-3-sulfonic acid, or with 2 mols. of 1-hydroxynaphthalene-4-sulfonic acid, or with 2 mols. of 1-hydroxynaphthalene-5-sulfonic acid, or with 2 mols. of 2-hydroxynaphthalene-6-sulfonic acid, or with 2 mols. of 2-hydroxynaphthalene-8-sulfonic acid, or with 2 mols. of 1-hydroxynaphthalene-3,6-disulfonic acid, or with 2 mols. of 1-hydroxynaphthalene-3,8-disulfonic acid, or with 2 mols. of 1-hydroxynaphthalene-4,8-disulfonic acid, or with 2 mols. of 2-hydroxynaphthalene-3,6-disulfonic acid. All of these products dye

animal fibers from acid bath in fast shades, varying from scarlet-red to blue-red, red-orange, yellow-orange, pure red, yellow-red, orange, and orange-red.

**Mordanting leucotriphenylmethane azo dye.** SOC. ANON. POUR L'IND. CHIM. À BÂLE. Swiss 77,661, May 16, 1918. The diazo compd. of 4,4'-tetraethyldiamino-2'-amino-3'-hydroxytriphenylmethane-4'',6''-disulfonic acid is coupled with  $\beta$ -naphthol. The product is sol. in  $H_2O$  with a blue color, and in concd.  $H_2SO_4$  with a brown-violet color, and dyes wool from acid bath in greenish blue shades which are after-chromable to a fast greenish blue, or may be converted by treating with Cu salts to a pure fast blue.

**Mordanting azo dyes.** SOC. ANON. POUR L'IND. CHIM. À BÂLE. Swiss 78,013-20, June 17, 1918. Additions to 77,539 (C. A. 12, 2448). Dyeings on animal fiber, rendered fast by after-treatment with Cu salts, are obtained, as specified. They dissolve in  $H_2O$  and in concd.  $H_2SO_4$  with characteristic colors. Diazotized 4-sulfo-2-amino-1-hydroxybenzene-6-carboxylic acid, coupled with benzoylacetic-*o*-carboxylic acid, dyes animal fibers in brown shades, changing to blue upon after-treatment with Cu salts. Diazotized 4-nitro-2-amino-1-hydroxybenzene coupled with benzoylacetic-*o*-carboxylic acid yields brown dyeings converted to violet shades by treatment with Cu salts. Diazotized 6-nitro-2-amino-1-hydroxy-4-methylbenzene coupled with benzoylacetic-*o*-carboxylic acid yields olive-brown shades changing to blue upon treatment with Cu salts. Diazotized 4,6-dinitro-2-amino-1-hydroxybenzene, coupled with benzoylacetic-*o*-carboxylic acid yields brown shades changing to violet-blue upon treatment with Cu salts. Diazotized 1-amino-2-naphthol-4-sulfonic acid coupled with *peri*-naphthindandione yields violet-brown shades changing to bordeaux-red upon treatment with Cu salts. Diazotized 2-amino-1-hydroxybenzene-4-sulfonic acid coupled with *peri*-naphthindandione yields yellow-orange shades, which change to red-brown upon treatment with Cu salts. Diazotized nitro-1-amino-2-naphthol-4-sulfonic acid coupled with *peri*-naphthindandione yields brown shades, which change to red-brown upon treatment with Cu salts.

**Dyes from waste sulfite liquor.** J. PURING. U. S. 1,283,296, Oct. 29. 100 cc. of 30° Bé waste sulfite liquor is mixed with 10 g. of  $\alpha$ -naphthylamine and the latter is dissolved by gentle heating. The material is then cooled and 2-25 cc. strong  $HNO_3$  added. Intumescence results with production of a gray porous mass. A 1-2% soln. formed from this product dyes wool, silk or leather directly by mere immersion, removal, washing and drying. The shade produced depends upon the proportion of  $HNO_3$  used. With small amts. of  $HNO_3$ , the dye gives flesh-colored tints; with larger, bright yellows, and with intermediate proportions intermediate shades. In some instances additional  $HNO_3$  may be dissolved in the dye bath itself. Different results are obtained by adding the  $HNO_3$  in stages. E. g., if to a mixt. formed from the  $\alpha$ -naphthylamine and waste sulfite liquor, in the same quantities as above, there be added 2.5%  $HNO_3$  in successive small portions with const. stirring, a reddish brown  $H_2O$ -sol. compn. is obtained. This will dye flesh color. If 2.5% more  $HNO_3$  be added, the compn. assumes a violet color and will dye wool and silk brown from a neutral bath. On adding 5% more acid, a violent reaction takes place and the mass intumescs. On drying, this product forms a blue-black powder, dyeing silk and wool a yellow-brown. Using 20% of  $HNO_3$  in all, a brownish yellow powder is obtained which is more sol. than the product obtained with a total of 10% of acid and which dyes wool and silk bright yellow from a neutral bath. Various dyes of somewhat similar character may be also obtained by using, instead of  $\alpha$ -naphthylamine, phenol, cresols, aniline, benzene, toluene, or xylene. The colors produced on wool, hair, silk or leather are fast to soap,  $NH_4OH$ , soda and bleaching soda. Chromic acid and bleaching powder change some of the shades produced.

**Dyes mixed with soap.** C. C. HUFFMAN. U. S. 1,283,519, Nov. 5. In combining dyes with soap, a vegetable oil such as olive or corn oil is saponified with NaOH or KOH and a soln. of an aniline dye such as "acid red" is added when sapon. is only partially completed. The mixt. is agitated and molded at a temp. of about 50° and the reaction is permitted to continue to completion. The temp. of the mass, due to reaction, rises about 30° during the first 2 hrs. after being placed in the mold, and then, after gradually lowering to room temp. the material is slabbed and pressed into cake form.

**Substitute for sericin soap in dyeing silk.** P. SCHMID. U. S. 1,284,152, Nov. 5. A substitute for sericin soap in dyeing silk is obtained by boiling silk wastes containing silk-worm chrysalides with H<sub>2</sub>O to which has been added a small proportion of mineral acid, *e. g.*, 3% of H<sub>2</sub>SO<sub>4</sub>.

**Foam baths for treating textile materials.** P. SCHMID. U. S. 1,281,670, Oct. 15. The object of the invention is to provide foam baths without the use of soap, Na<sub>2</sub>CO<sub>3</sub>, silk chrysalides or silk wastes. Copse, chippings or sawdust of fir wood, pine wood or similar woods or the leaves of the beech, maple, poplar or acacia are placed in the bottom of the vessel in which the foam bath is to be prepd. and boiled with H<sub>2</sub>O. A small amt. of Na<sub>2</sub>CO<sub>3</sub> or soap may be added to the H<sub>2</sub>O. The heat kills any bacteria present and a foam is formed which rises into contact with textile materials which are placed in the upper part of the vessel. The method may be employed in ungumming, phosphating, silicating, cleaning, fulling, dyeing or mordanting. Fibers of animal, vegetable or chemical origin may be treated. The material treated may be supported in any suitable manner to allow it to come into contact with the foam but not with the solids and liquid from which the foam is produced and before the foam treatment the material may be satd. with Na<sub>2</sub>CO<sub>3</sub> soln.

**Woven fabrics.** K. MIYAKE. Brit. 119,428, June 7, 1918. The leaves of the coconut palm are rendered suitable for weaving into cloth, hats, mats, slippers, bags, etc., by boiling in H<sub>2</sub>O, splitting, and tearing into strips, which are boiled for 1 to 2 hrs. in a soln. of 4-8 lbs. of Na<sub>2</sub>CO<sub>3</sub> in 100 lbs. of H<sub>2</sub>O. The strips are then washed and placed for 1 to 3 days in a bleaching soln. comprizing 100 lbs. of H<sub>2</sub>O, 1-3 lbs. of Na<sub>2</sub>O<sub>2</sub>, 1-2 lbs. K<sub>2</sub>C<sub>2</sub>O<sub>4</sub>, and 50-100 g. of H<sub>2</sub>SO<sub>4</sub>, the material preferably being disturbed from time to time. The strips are then washed and dried in the shade while exposed to an air current, and when dried roll up from both sides and become smooth and semi-transparent. The finished threads are strong, light, elastic, waterproof, and of a good feel.

## 26. PAINTS, VARNISHES AND RESINS.

A. H. SABIN.

**Waterproofing composition.** W. RODENBERGER. U. S. 1,283,913, Nov. 5. A mixt. for coating and waterproofing leather, textile fabrics or other materials is formed of white lead, linseed oil, coal tar, paraffin, turpentine, corn starch, poppy oil and a coloring material such as a lead pigment.

**Lacquering.** SOC. ANON. L'HELICE INTEGRALE ANCIENS ETABLISSEMENTS L. CHAUVIERRE. Brit. 118,610, July 23, 1918. Lacquered articles are placed in an app. provided with means for regulating the temp. and humidity of the air. Ozone, etc., may be introduced, and the elec. tension may be regulated. The articles are protected by screens from ultraviolet rays.

**Hardening varnish.** C. A. CUTLER. U. S. 1,283,685, Nov. 5. Varnished articles are treated, to harden the varnish, by placing them within a closed chamber having a permeable wall on one side, heating the air within the chamber at the side opposite

to the permeable wall to a temp. higher than that of the external air, the air as it rises being cooled by contact with the wall of the chamber and a portion of the air thus cooled being forced out through the permeable wall near the top of the chamber to the external air and some of the external air being drawn into the chamber through the lower portion of the permeable wall.

**Varnishing balloons.** H. E. HONEYWELL. U. S. 1,281,374, Oct. 15. Balloon cloth is sized in a mixt. formed of PbO 8 oz., ocher 8 oz. and linseed oil 1 gal., passed between rolls to remove excess sizing, dried, and after making up into balloons is rendered tacky by a coating of varnish and then coated with a mixt. of Al powder 1 and French chalk 2 parts.

**Oxidizing and polymerizing vegetable oils.** J. K. BLOGG. U. S. 1,284,572, Nov. 12. Vegetable oil to be oxidized and polymerized, *e. g.*, linseed oil for use in printers' varnish, is rapidly heated in a closed retort over an open fire and a current of air is passed through the oil by suction applied to the upper portion of the retort. When the temp. approaches the flash point of the oil, the supply of air is discontinued.

**Writing-ink.** M. SHINOZAKI. U. S. 1,282,302, Oct. 22. A writing-ink is formed of a soln. of caustic alkali, induline or other dye, lampblack and soft soap. The lampblack is retained in suspension.

**Printers' ink.** L. E. BARTON and H. A. GARDNER. U. S. 1,283,455, Nov. 5. Titanic oxide which may be coalesced with sulfate particles is added to printers' inks or colors of usual character otherwise, for the purpose of improving their opacity, smoothness and durability.

**Phenol-methylene condensation products.** REDMANOL CHEMICAL PRODUCTS CO. Brit. 119,252, July 25, 1917. A fusible anhydrous resinous condensation product is obtained by mixing together an excess of a phenol, a methyleneamine compd. such as hexamethylenetetramine, and a small proportion of coal-tar creosote oil, and heating to effect condensation. A proportion of a methylene compd. sufficient to form eventually an infusible product may then be added, and the mixt. cooled, comminuted, mixed with a filler, rolled between differential rollers to cause a certain amt. of reaction, and finally pulverized. The product so obtained can be converted into the final insol. substance by heating in molds. The initial fusible resin may be dissolved in solvents to give a varnish which may be mixed with hexamethylenetetramine to render it capable of hardening on being heated. Cf. 9,291, 1914 (*C. A.* 9, 2715).

**Phenol-methylene condensation products.** REDMANOL CHEMICAL PRODUCTS CO. Brit. 119,253, July 25, 1917. The process of producing a fusible anhydrous resinous condensation product described in 119,252 (see *supra*) is modified by using a large excess of phenolic compd. at the outset, condensing it with the methyleneamine compd. by heat, then blowing off a portion of the free phenol from the product and adding the coal-tar creosote oil. The product is subsequently mixed with a further amt. of methyleneamine compd. and fillers worked up as described in the aforesaid specification.

**Non-conducting coverings.** F. H. ADDIS. Brit. 119,134, Oct. 29, 1917. A non-conducting covering for the roofs of railway carriages or like vehicles in hot climates consists of a compn. containing ground cork, woody fiber, oxidized oil (preferably linseed), and mineral matter, such as kieselguhr, chalk, or baryta, applied to a fibrous backing, such as canvas. Suitable proportions for the compn. are 75% of ground cork or woody fiber, 16% of oxidized oil, and 9% of mineral matter. Cf. 7,354, 1890, and 267, 1902.

**Resin.** F. W. SPERR, JR. and M. DARRIN. Can. 184,890, June 11, 1918. Crude solvent naphtha is subjected to heat and pressure in the presence of a catalytic agent.

27. **FATS, FATTY OILS AND SOAPS.**

E. SCHERUBEL.

The French soap and oil industry. ANON. *Chem. Trade J.* 63, 361-2(1918).

E. H.

The cottonseed industry of India. ANON. *Agr. J. India* 13, 549, 1(1918).—Several Indian cotton seeds give an average of 19.67% oil, 34.68% meal and 45.65% husk.

J. J. SKINNER.

Rapid changes in palm oil. BALLAND. *Compt. rend.* 167, 673-4(1918).—Three samples representing lots procured during Jan., Feb. and March, 1917, were analyzed May 25, with the following results:

|                         | 1.    | 2.    | 3.    |
|-------------------------|-------|-------|-------|
| Fatty substances.....   | 96.0% | 98.7% | 99.0% |
| Impurities.....         | 4.0   | 1.3   | 1.0   |
| Free acid as oleic..... | 61.2  | 19.4  | 8.3   |

The oils were rancid and the free acid continued to increase to over 75%. The oils were intended for consumption by colonial troops, but for this purpose the free acid should not exceed 1%. Palm oils appear to undergo a spontaneous sapon. which unfits them for edible purposes after some months.

E. SCHERUBEL.

New method for the exact determination of the fatty acid content of soaps. E. BOSSEHARD AND F. COMTE. *Helvetica Chimica Acta* 1, 251-70(1918).—From 4 to 6 g. of soap are dissolved in hot H<sub>2</sub>O and transferred to the "sapometer" of Huggenberg and Stadlinger, which contains 25 to 30 cc. of N H<sub>2</sub>SO<sub>4</sub> and a few drops of methyl orange. Water is added to the 100 mark, and after cooling, 50 cc. of a mixt. of equal parts of ether and petroleum ether. After shaking, 50 cc. more of the ether mixt. are added and after sepn. into layers, the acid layer is drawn off, the ether layer washed with 100 cc. H<sub>2</sub>O, and the vol. read. Next 25 cc. are drawn off into a weighed Erlenmeyer flask contg. a known wt. (about 5 g.) of PbO and a few pieces of pumice. After shaking, the solvent is evapd. and the flask evacuated by means of a water pump. The flask is next dried for 20 min. at 60° in a Victor Meyer crucible drying oven under reduced pressure. The increase in wt. of the flask is due to the fatty acid anhydrides which have combined with the PbO. This method has been thoroughly tested on pure fatty acids, mixts. of fatty acids and various soaps, including rosin soaps, and has been found to give accurate results.

E. SCHERUBEL.

Clarifying oils. A. G. MUNRO. U. S. 1,284,750, Nov. 12. After refining cottonseed or similar oils with fuller's earth, the oil is sepd. from the latter by successive treatment with air, H<sub>2</sub>O and steam. The pat. describes app. for carrying out the method.

High-melting point fatty acids and other products from wool-fat or similar substances. I. LIRSCHÜTZ. U. S. 1,284,723, Nov. 12. Wool-fat is saponified or hydrolyzed, washed with alc. at ordinary temp. until a wax-like residue remains and the latter is then treated with a suitable solvent such as ether or CS<sub>2</sub> to ext. the unsaponifiable portion and obtain as a residue soaps of fatty acids of high m. p. The soln. obtained from the wax-like product is allowed to crystallize to obtain the unsaponifiable H<sub>2</sub>O-miscible substances from it. A soft unsaponifiable mass is obtained which is sol. in ether, C chlorides and CS<sub>2</sub> and in acetone, of a light yellowish color, very miscible with H<sub>2</sub>O and m. 45-50°. This substance is adapted for use in ointments.

Hydrogenating liquids catalytically. R. F. STEWARD. U. S. 1,284,488, Nov. 12. Cottonseed oil or other liquid to be hydrogenated is spread in film form upon a

rapidly rotating surface, by centrifugal action, and while thus spread is subjected to the action of H and a catalyst.

**Apparatus for extracting grease or oils with solvents.** W. E. GARRIGUES. U. S. 1,282,407, Oct. 22. The app. comprizes a horizontal rotary extn. drum with pipe connections for leading hot gases into the lower portion of the drum.

**Catalyst.** A. SCHWARCMAN. U. S. 1,292,296, Oct. 22. A catalyst suitable for use in hydrogenating oils or fats is formed of finely ground roasted quartz and fuller's earth carrying finely divided colloidal Ni. U. S. 1,282,297 describes the production of a catalyst for use in hydrogenating oils, formed of finely divided native amorphous  $\text{SiO}_2$ , free from pores and of the character occurring in asbestos deposits, of a fineness of 400 mesh or greater and carrying reduced Ni. Cf. C. A. 12, 2700.

**Fatty acids from used soap baths.** R. CLAVEL. Swiss 78,280, July 1, 1918. Soap-decomposing agents are used which do not contain S, in order that a mechanical mixt. merely of fatty acid,  $\text{H}_2\text{O}$ , and impurities is produced, and not a permanent emulsion.

**Fatty acids from used soap baths.** R. CLAVEL. Swiss 78,281, July 1, 1918. Soap color baths containing albumin, *e. g.*, used soap baths, are used to sep. the fatty acid, in conjunction with baths containing tannin.

## 28. SUGAR, STARCH AND GUMS.

---

A. HUGH BRYAN.

**Boiling-house recovery.** G. H. HALDÉN. *Intern. Sugar J.* 20, 467-74(1918).—A thorough investigation of the various sources of loss which cause the actual boiling-house recovery to differ from the theoretical. A. GROSS.

**Measuring the color of sugar products.** F. W. ZERBAN. *Louisiana Planter* 61, 282-3(1918).—Some difficulty was encountered in making accurate comparative tests of the decolorizing effect of vegetable carbon. The Hess-Ives Tint-Photometer was used and proved of great usefulness. A. GROSS.

**New tables for finding purity of massecuite.** NORBERT CLAIBORNE. *Sugar* 20, 454-5(1918). A. GROSS.

**Refining of raw sugars.** C. G. LEONIS. *Sugar* 20, 394-7, 440-1(1918).—A complete discussion of the subject from the wash plant house to the finished product is given. The various calcns. used and the methods of operation are described in detail. Many data are inserted which have proved useful from an operating standpoint. A. GROSS.

**Beet sugar factories.** FRANK COXON. *Intern. Sugar J.* 20, 456-9(1918).—Some points of interest in station equipment are described. A. GROSS.

**Nitrogen in French sugar beets.** E. SAILLARD. *Sugar* 20, 451-2(1918).—Analyses of beets are given and comments are made upon the loss of the N. A. GROSS.

**Complete electrification of sugar mills.** C. G. HADLEY. *Elec. World* 72, 1022-3(1918).—Description of the satisfactory results in elec. equipment obtained at the New Cuban Mills. C. G. F.

---

**The Abbé and Pulfrich refractometers (ANON.)** 1. Industrial preparation of lactic acid from sugar beets (BONELLI, GULINELLI) 10.

---

**Dextrin.** W. W. McLAURIN. U. S. 1,283,839. Nov. 5. Concd. dextrin in soln. or liquid form is made by placing substantially equal quantities of commercially

pure starch and  $H_2O$ , together with less than 1% of acid such as  $HCl$ , in a closed vessel, heating indirectly by steam to a temp. of about  $137^\circ$  while producing a corresponding high pressure on the materials and maintaining this pressure and continuing the treatment until substantially complete conversion has been effected and a colorless soln. of dextrin, liquid at a temp. of  $15-20^\circ$ , is obtained.

**Dextrin.** W. W. McLaurin. U. S. 1,284,120, Nov. 5. A normally hydrolyzed, substantially clear dextrin soln. or liquid having a concn. of about 50% and suitable for use without further treatment as a coating, adhesive, or for the impregnation of paper, wood or other materials, is made from starch, *e. g.*, by the method described in U. S. pat. 1,283,839 (*supra*).

**Stiffening substance for laundry.** O. LOBECK. Swiss 77,911, June 1, 1918. A substitute for starch contains powdered hydrophile colloids such as glue, gelatin, gum arabic, agar-agar, dextrin, casein, albumin, or tragacanth, alone or mixed. The product is instantly sol. in hot  $H_2O$ . A drying agent may be added, such as borates, Mg salts, Ca salts.

## 29. LEATHER AND GLUE.

ALLEN ROGERS.

Mr. Small's modification of the hydrochloric acid-formaldehyde method for separating tannins, with special application to chestnut oak bark and chestnut wood. Committee report. T. G. GREAVES. *J. Am. Leather Chem. Assoc.* 13, 388-95 (1918). —The object of the committee work was to find out what agreement could be expected between different laboratories using Small's  $HCl-CH_2O$  method (*C. A.* 5, 2346) for the quantitative detn. of pyrogallol tannins, especially chestnut wood ext., in admixture with chestnut oak bark ext. The instructions sent out are given and they involve only a slight change of the original method so as to bring the drying into the limits of the working day. Two samples of pure chestnut oak bark ext. and 2 of chestnut wood ext. together with 1 sample each of chestnut oak bark and chestnut wood were sent to each of the 10 operators. The av. ppt. weights obtained are given. The results are also calcd. to % of ext. for which purpose the typical ppt. weights of chestnut oak bark and chestnut exts. were taken as 0.1600 and 0.0150, respectively. The formula for this calcn. is given. The final av. ppt. weights obtained for the 2 chestnut oak bark exts. were 0.1572 and 0.1798, corresponding to 2% chestnut ext. and 98% chestnut oak bark ext. for one and —14% chestnut ext. and 114% chestnut oak bark ext. for the other. The figures for the chestnut wood exts. were 0.0273 and 0.0228, indicating 92 and 95% chestnut wood ext. The av. results on the chestnut oak bark were 0.1845 and for the chestnut wood 0.0132. Some idea of the variation between duplicate detns. is given in a table showing the highest and lowest ppt. wt. obtained by each operator on the 4 exts. The results show that the method, being based on the figure obtained for the ppt. wt. which is not the same for all samples, cannot be classed as an exact method. It is useful, however, in detecting accidental mixing or wilful adulteration.

R. W. FREY.

**Leather substitutes.** J. WARD. Brit. 119,304, Oct. 16, 1917. A substitute for leather consists of coarse felt impregnated and covered with a mixt. of leather powder, vulcanized rubber powder, and free S heated to a semi-liquid state, with which may be incorporated resin,  $Na_2SiO_3$ , and coloring matter. Leather scrap or waste is roasted in a hot-air kiln until it is crisp and is then ground into a powder. Eight parts by wt. of the powder are mixed with 2 parts of vulcanized rubber which has previously

been worked into a fine powder in a cold-chamber grinding mill, the mixt. being rendered more solid if desired by the addition of one part each of resin and  $\text{Na}_2\text{SiO}_3$ . One part of S is added, and a coloring ingredient also if a colored product is required. After mixt. and heating, the material is forced in a semi-liquid condition into the open pores and coated on the surface of coarse felt and cooled until solid.

**Liquid mixture for waterproofing felt.** F. PICARD. U. S. 1,281,650, Oct. 15. A liquid mixt. for treating felt to produce a *substitute for leather* is formed of linseed oil 5 lbs., rosin 5 lbs., gutta percha 5 lbs., gum arabic 5 lbs., shellac 80 lbs. and gasoline or alc. 40 gals.

**Tanning.** R. BOHN, O. BALLY and H. WOLFF. U. S. 1,281,494, Oct. 15. De-limed hides are tanned by treatment with a bath containing an anthracenesulfonic acid, *e. g.*, a soln. formed from  $\text{H}_2\text{O}$ , a small amt. of  $\text{H}_2\text{SO}_4$  and alkali metal salts of 1,5- and 1,8-anthracenedisulfonic acids, dichloroanthracenedisulfonic acids or phen-anthrene- or fluorenesulfonic acids.

**Tanning agent.** CHEM. FABRIKEN WORMS AKT.-GES. Swiss 78,282, July 1, 1918. A tanning agent is obtained by sulfonating tar oil and treating it with  $\text{HCHO}$ . The product tans animal gluc, is sol. in  $\text{H}_2\text{O}$ , and exhibits the properties of ordinary tannins. The dry substance carbonizes upon heating, without previous fusion. The product is sol. in  $\text{H}_2\text{O}$  as well as in dil. acids and alkalies, but insol. in org. solvents which are not miscible with  $\text{H}_2\text{O}$ .

**Tanning with aluminium salts.** O. RÖHM. Swiss 77,935, June 1, 1918. Al formate or acetate is used, or the usual alum tanning process is followed by treatment with wash  $\text{H}_2\text{O}$  containing the formate or acetate of an alkali or alk.-earth metal, *e. g.*, Ca formate or acetate.

**Gelatin.** T. TADA. Brit. 119,210, June 3, 1918. See Jap. 32,303 (C. A. 12, 2259).

# CHEMICAL ABSTRACTS

Vol. 13.

FEBRUARY 10, 1919.

No. 3

## I. APPARATUS.

L. C. JONES.

**Absorption pipets.** E. VAN ALSTINE. *J. Ind. Eng. Chem.* 11, 51-2(1919), illus.—The app. has been designed with the purpose of accomplishing complete and rapid absorption of gases without the use of glass beads or rods. E. J. C.

**New reflux condenser.** JAMES J. BAJDA. *J. Ind. Eng. Chem.* 11, 52(1919), illus. E. J. C.

**A simple and efficient condenser.** R. HOWDEN. *Chem. News* 117, 368(1918).—A condensing arrangement is described and illustrated which can readily be constructed from ordinary lab. materials. It has proved very efficient in the distn. of ether residues. E. J. C.

**Device for rapid cleaning of pycnometers.** M. DUGARDIN. *Ann. chim. anal.* 23, 125-6(1918).—The device consists of a right-angled glass tube, the longer leg of which is drawn out to a length somewhat greater than the height of the app. and to a diam. sufficiently small to slide into the neck of the app. without binding. The other end of the tube is inserted into the neck of a 1-l. flask fitted with a tight 2-hole stopper; through the 2nd hole another tube connects with a vacuum pump. A 3rd tube, one end of which is drawn out to a very small diam., the other end being connected to a water tap by means of a rubber tube closed by a Mohr pinch-cock, is fastened to the vertical leg of the 1st tube by means of rubber bands. In operating, the pycnometer, full of the liquid to be evacuated, is raised sufficiently to allow the tube to reach to the bottom, and at the same time the pump is started. When all the liquid has passed into the flask, the pycnometer is again lowered until the mouth of the tube is in the narrowest part of the neck. The pinch-cock is then released and water allowed to run into the app. The partial vacuum causes the water to be forced over every part of the inner surface, insuring a thorough cleaning. When the app. is full of water, the pinch-cock is closed and the operation repeated from the beginning as many times as necessary. J. L. WILEY.

**Telescopic focusing apparatus for photomicrography.** A. F. HALLIMOND. *Engineering* 106, 448(1918).—A brief description of the apparatus with accompanying diagram. S. G. SIMPSON.

**Helps on proper maintenance of pyrometers.** A. GEMMELL. *Elec. Rev.* 73, 980-1(1918).—Illustrated account of a number of practical methods for the care and protection of pyrometer ends and leads. One diagram shows an arrangement of protecting pipes and fire ends in a retort; another, a simple method of swinging connecting wires out of the way when opening the retort. C. G. F.

**Electrical welding apparatus.** ANON. *Elec. Rev.* 73, 984-6(1918).—A review. C. G. F.

**Modern packings for absorption towers. Coke acid filters.** A. HUTIN. *Rev. prod. chim.* 21, 169-70(1918).—To obtain the max. absorption of a gas in a liquid, two conditions must be satisfied. First, there must be max. surface exposure of the liquid to the gas; second, there must be uniform distribution of the fluids in the ab-

sorption app. so that the so-called "rat-holes" are not formed. A mathematical formula is derived by H. to show that the surface of exposure of a packing, made in the form of a cylinder with height equal to diameter, varies inversely as the diameter. It is calcd. that the max. surface is obtained by the use of 3 concentric cylinders. A cheap and efficient packing may be made from bottles, cut in half, with the top half placed neck down in the bottom half. Gas coke is not suitable for use as a packing in coke filters, because the coke contains  $\text{Al}_2(\text{SO}_4)_3 \cdot 27\text{H}_2\text{O}$  and  $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$  which clog the pores of the coke and form dil. solns., contaminating the acid. Metallurgical coke is best. Materials, having high porosity, are desirable. An efficient packing can be made from kieselguhr as a base. One-fourth of the vol. of this packing is solid matter. For use in acid filters a packing was made in the laboratory as follows: Glass was ground to 30 mesh. 99% of this powder was mixed with 0.5% finely pulverized caking coal and 0.5% powdered asphalt. The mixt. was quickly heated in a muffle. Due to the rapid evolution of a large amount of gas, the mass swells up and becomes so porous that when the operation is carried out properly the product will float on water. A practical test of this packing was not made, but the advantages of its use are evident as (1) its larger contact surface, (2) its resistance to acids and vapors, (3) its cheapness.

ISMAR GINSBERG.

**Mixing-drums for dry material.** E. A. KÜPPERS. *Chem. App.* 5, 65-67(1918).—Description and working directions are given for mixing-drums in general and of the Mühlau, Häberle, Prosper types in particular. Nine sketches are included.

TH. VERHEGGEN.

**Carrying away of masses of boiling liquids in evaporating apparatus. A monograph on scum-separators, their construction, working and action.** HUGO SCHRÖDER. *Chem. App.* 4, 97-99, 105-8, 113-6, 121-2, 129-32, 137-9, 146-9, 156-8, 164-6, 171-2, 180-2, 185-7(1917); 5, 4-6, 9-11, 19-22, 33-4, 41-5, 51-3, 57-60(1918).—In evapg. app. the masses of vapors carry away greater or less quantities of liquid, partly in form of drops, partly in the state of scum, or a mixt. of both. This fact is often the source of important losses which are to be avoided, either for the sake of the residue or to obtain a condensate free from the original admixture. The author describes the different scum-separators. Eighty-six sketches are included. TH. VERHEGGEN.

**History of the gasometer.** FRANZ M. FELDHAUS. *Z. angew. Chem.* 37, I, 164 (1918).

TH. VERHEGGEN.

**Acetylene generator.** W. H. ROWE. U. S. 1,285,799, Nov. 26.

**Gas-absorption apparatus for determinations of carbon dioxide.** A. BUTCHER. U. S. 1,285,927, Nov. 26.

**Apparatus for making, storing or transporting corrosive chemicals.** I. WOLF. U. S. 1,285,537, Nov. 19. The app. comprizes a frame within which is supported a screen of expanded metal work carrying mineral "base material" with a lining of acid-proof material such as Pb. The app. is especially adapted for tank walls or stirrer.

**Hollow ware of tungsten or other refractory materials.** C. A. PFANSTIEHL. U. S. 1,286,089, Nov. 26. Hollow ware, such as dishes for lab. work, are formed of powdered W, Ta, MgO or oxides of W, Ta or Th by inserting a body of Cu into a mass of the powder, compressing the powder around the Cu under a pressure of 130-160 tons per sq. in. (at which pressure the Cu flows and becomes to a certain extent embedded in the compacted refractory material) and the embedded Cu may then be removed by the action of  $\text{HNO}_3$  or other solvent selected with reference to the refractory material employed so as not to attack the latter.

**Retorts.** JNO. WEST and WM. WILD. Can. 187,765, Dec. 3, 1918. A series of

retorts has in combination with it combustion chambers at the inlet end of the retorts, secondary air-heating chambers at the outlet-end of the retorts and waste-gas circulating chambers between the said combustion and air-heating chambers.

**Water-cooled buckstay.** G. L. DANFORTH, JR. *Can.* 187,816, Dec. 3, 1918. A buckstay of a rolled metal slab has a drilled aperture therethrough and water connections to the aperture comprising a pipe extending downwardly within the aperture.

## 2. GENERAL AND PHYSICAL CHEMISTRY.

WILLIAM D. HARKINS AND E. B. MILLARD.

**Science and the future.** A. A. CAMPBELL SWINTON. *J. Roy. Soc. Arts* 67, 7-19 (1918); *Electrician* 81, 663-4 (1918).—"There is one method of acquiring a scientific education to which not nearly enough attention is paid, the private reading of technical books and of periodic scientific literature." The most important problem of the future is one of photochemistry: to find the best means of utilizing the "enormous flood of solar radiant energy." C. G. F.

**Chemical nomenclature.** E. J. CRANE. *J. Ind. Eng. Chem.* 11, 72-3 (1919).—The discussion is accompanied by the statement of a few preferences concerning which it is thought that there will be no disagreement and which represent not so much C.'s opinion as the "accumulated experience from the constant effort which has been made in the office of *Chemical Abstracts* to keep the abstract journal an example of good nomenclature." Greater exactness in our chemical records is the object that has been held in mind. E. H.

**National prestige in scientific achievement.** P. G. NUTTING. *Science* 48, 605-8 (1918). E. J. C.

**The criteria in the declaration of chemical independence in the United States.** I. NEWTON KUGELMASS. *Science* 48, 608-12 (1918).—An address. E. J. C.

**The two hundred and fiftieth anniversary of chemical industry in America.** C. A. BROWNE. *J. Ind. Eng. Chem.* 11, 16-9 (1919).—The first origins of chemistry in America are discussed. John Winthrop (1606-1676), a biography of whom is given, deserves the honor of being called the first American chemist in point of time. E. J. C.

**British university resources compared with those of the United States.** Education Committee, Brit. Science Guild. *Elec. Rev.* 73, 1010 (1918).—In proportion to population the U. S. has twice as many students of University standard as England; Scotland has more than three times as many and Germany has nearly three times as many. There are only 5,000 full-time students of science and technology in the United Kingdom in comparison with nearly 17,000 in Germany and 34,000 in U. S. Other details are given. C. G. F.

**Prof. Dr. Ed. Mulder.** W. P. JORISSEN. *Chem. Weekblad* 15, 1503-16 (1918).—This biographical sketch is accompanied by a bibliography of Dr. Mulder's contributions to chemistry. E. J. C.

**Ernst Cohen.** W. P. JORISSEN. *Chem. Weekblad* 15, 1404-17 (1918).—Biographical with photograph. E. J. C.

**Bibliography of the publications of Ernst Cohen.** H. R. KRUYT. *Chem. Weekblad* 15, 1432-70 (1918).—Eight books and 225 papers have been contributed. E. J. C.

**The piezochemical investigations of Prof. Dr. Ernst Cohen.** A. L. TH. MOERSVELD. *Chem. Weekblad* 15, 1438-51 (1918). E. J. C.

**The electrochemical investigations of Prof. Dr. E. Cohen.** W. D. HELDERMAN. *Chem. Weekblad* 15, 1426-37 (1918). E. J. C.

**Investigations on allotropy by Prof. Dr. E. Cohen.** TH. STRENGERS. *Chem. Weekblad* 15, 1418-25(1918). E. J. C.

**Report of the chemist.** CARL L. ALSBERG. Chief of Bur. of Chemistry, U. S. Dept. of Agr. *Annual Repts. Dept. Agr.* 1918, 24 pp.—The work of the year ending June 30, 1918 is outlined. Investigations suitable to be abstracted have been or will be abstracted as they appear as separate publications. E. J. C.

**Annual report of the Director of the Bureau of Standards to the Secretary of Commerce for the fiscal year ending June 30, 1918.** 206 pp.(1918).—Abstracts have been or will be published of the individual investigations as reported in separate publications. E. J. C.

**Eighth annual report of the Director of the Bureau of Mines.** VAN H. MANNING, Director. 124 pp. (1918).—The rept. is for the fiscal year ended June 30, 1918. A large part of the activities were in connection with war work. Abstracts have already been published or will be published later as the reports of the various individual investigations appear. E. J. C.

**Modification of the periodic table.** INGO W. D. HACKH. *Am. J. Sci.* 46, 481-501(1918).—From the curves obtained by plotting the relative electromotive forces of the elements and their max. polar numbers against their atomic numbers, it can be predicted that no new rare gas can be discovered. Such a gas would demand characteristic properties of about 13 other elements and of these 13 elements none is known. The periodic system is best expressed in a continuous curve, *e. g.*, a spiral; but as such graphic representations are difficult, a table has been derived which in H's. opinion shows the relationship among the elements better than the customary table. D. MACRAE.

**Experimental researches on the thermal conductivity of gases. I and II.** S. WEBER. *Ann. Physik* 54, 325-6, 437-62(1918); *Sci. Abstracts* 21A, 268.—The principle feature of Part I is the investigation of convection effects and their elimination. Results for dry air free from CO<sub>2</sub> are given. Part II contains data for H, He, Ar, N, O, CH<sub>4</sub>, CO<sub>2</sub>, and "nitrous dioxide," and methods for prepg. the pure gases and tables of results for the thermal cond. The dependence of thermal cond. on temp. is dealt with at some length. The results obtained show a special behavior of H; at higher temps. this gas is diatomic, but at temps. near that of liquid air it gives the monatomic curve, which at the lowest point lies almost on the A curve. The course of the curve is in consonance with the loss by H of internal energy at lower temp. In the group of diatomic substances, O, N, and CO behave similarly, the curves being parallel to the A and He curves. At lower temps. the curves for O and N appear to approach the A curve. D. MACRAE.

**Theoretical and experimental researches on the thermal conductivity of gas mixtures. III.** S. WEBER. *Ann. Physik* 54, 481-502(1918); through *Sci. Abstracts* 21A, 268-9(1918); cf. preceding abstract.—On account of the great importance of the halfwatt lamp in lighting technology, the thermal conds. of gas mixts. have acquired enhanced interest. Knudsen's method is employed for deriving a formula which shall represent the thermal cond. of a gas mixt. This formula is then discussed in its application to common gas mixts., *e. g.*, N and O, O and H, A and He, H and CO<sub>2</sub>. None of these usual gas mixts. gives a max. or minimum value of the thermal cond. when the theoretical values of the constants are used in the formula. Air, O-H mixts., and H-CO<sub>2</sub> mixts. are more rigidly examd. The discussions of some measurements of the thermal cond. at 0° of mixts. of N and A conclude the paper. D. MACRAE.

**Specific heats of lead-antimony alloys.** R. DURRER. *Physik. Z.* 19, 86-8(1918); *Sci. Abstracts* 21A, 269(1918).—The sp. heats of Pb-Sb alloys at const. temp. are a

linear function of the concn. within the temp. range of  $20^{\circ}$  to  $100^{\circ}$ . The method of Levin and Schottky was employed.

D. MACRAE.

**The electrical conductivity of acids and bases in aqueous solutions.** JNANENDRA CHANDRA GHOSH. *J. Chem. Soc.* 113, 790-9(1918).—This is an attempt to explain the abnormally high mobility of the  $H^+$  and  $OH^-$  in aq. solns. It is assumed that the observed cond. of  $H^+$  or of  $OH^-$  in  $H_2O$  is the additive effect of two processes, namely, (1) the transfer of electricity by the convection of charged bodies, and (2) the transference of the elec. charge through mols. of  $H_2O$  by the alternate process of dissociation and recombination during impact with  $H^+$  or  $OH^-$ . In the latter process  $H^+$ , for example, dissociates a  $H_2O$  mol. by impact and then combines the  $OH^-$ , while the H atom of the  $H_2O$  mol. which is farthest from the point of impact shoots off as a charged particle. Thus at each impact attended with dissociation, there is saved a distance proportional to the diameter of the  $H_2O$  mol. with the result that the  $H^+$  appears to have a velocity greater than its true velocity. Quant. application of this hypothesis permits the calcn. of  $\mu_{\infty}$  for strong acids and bases to about 1%. The apparently high activity coeff. of strong acids and bases in aq. soln. is also traced to this cause. A modified Ostwald equation  $(\alpha x)^2/(1-x)V = K$ , based on the consideration that only free ions have the capacity of regenerating undissociated mols., has been developed for weaker electrolytes,  $\alpha$  being the activity coeff. This equation becomes identical with Ostwald's diln. law in the case of very weak electrolytes where  $\alpha$  is nearly equal to one, and gives concordant values for the equil. const. in the case of transition electrolytes where Ostwald's equation is not applicable.

R. H. LOMBARD.

**Electrochemical behavior of metals.** A. SMITS. *Proc. Acad. Sci. Amsterdam* 21, 158-71(1918).—A translation into English of the paper abstracted in *C. A.* 12, 2479.

E. H.

**Calorimetric lag.** WALTER P. WHITE. *J. Am. Chem. Soc.* 40, 1858-72(1918).—No matter how vigorous the stirring in a calorimeter, the temp. of some parts will lag behind the rest as long as the temp. of all is changing. These lags, however, depending on thermal cond. usually have simple and definite laws, and error from them is easily avoided by proper treatment. (1) The lags of thermometers and other bodies within the calorimeter, which have already been discussed, are more carefully re-stated, and prove to be as follows, for the lag  $L$  (in minutes) of any single body, as a thermometer: (a) A principal effect,  $= LK\Delta\theta'$ , where  $K$  is the thermal leakage modulus of the calorimeter,  $\Delta\theta'$  the temp. rise; this is equivalent to a change in the effective heat capacity of the calorimeter; (b) an avoidable effect depending on change in *jacket* temp. which makes the effective heat capacity different in adiabatic work; (c) smaller effects  $= LK\eta$ , where  $\eta$  is the "cooling correction," a few percent of  $\Delta\theta$ . (2) The mathematically more considerable problem of the lag effect of external bodies (shields, the air, solid insulators) is attacked, and the same 3 kinds of lag effect are found to be possible in all cases. The effective heat capacity of a convection shield around a calorimeter can be made  $1/4$  the actual capacity, and appreciable change in this will seldom occur except through great carelessness. Insulating packings are very undesirable, on account of the time required for equil. Calorimeter covers of any other material than metal are undesirable from nearly every point of view. Temp. distribution in aneroid calorimeters also receives attention.

W. P. WHITE.

**The conditions of calorimetric precision.** WALTER P. WHITE. *J. Am. Chem. Soc.* 40, 1872-86(1918).—Changes in the magnitude of the thermal leakage modulus  $K$ , of the calorimeter, or in the magnitude of the thermal head  $\varphi$ , that is, the mean temp. difference of calorimeter and environment, do not, as a rule, change very much the errors in these quantities, and therefore are of advantage only as these quantities

are the multipliers of other errors. Thus, the thermal leakage effect ("cooling correction") is  $KT\phi$ , where  $T$  is *time*; hence diminishing  $T$  diminishes the effect of errors in  $K$  or  $\phi$ , diminishing  $K$  diminishes the effect of errors in  $\phi$ . Since errors in  $K$  are important only in protracted detns. it is only for them that a diminution in  $\phi$  is important. Hence, contrary to widely held opinion, 2 favorite methods of diminishing  $\phi$ , the adiabatic, and the practice of starting the calorimeter below the jacket in temp. do not appreciably diminish the effect of this one of the *main* thermal leakage errors. It also follows from the peculiarities of the leakage effect computation that they do not diminish the effect of the (purely thermometric) error in detg. the leakage rate. The effect of this error can be diminished in other ways. Errors connected with stirring become important in delicate measurements. They can be reduced by controlling the speed, and also, and more effectively, by proper design, and by diminishing  $K$ , which diminishes the need for stirring. Evapn. and lags are touched upon, and a mathematical treatment is given, apparently for the first time, of the error from conduction along wires.

W. P. WHITE.

**Calorimetric methods and devices.** WALTER P. WHITE. *J. Am. Chem. Soc.* 40, 1887-98(1918).—The general rules derived in the paper of the preceding abstract are applied in a discussion of the efficiency of, or best methods to use with, the following devices or methods, only the last of which is new: Water cap and submarine types of complete jacket; various stirring devices; vacuum-jacketed calorimeters; the adiabatic method; aneroid calorimeters; twin calorimeters; the measured shield. *Vacuum jacketed calorimeters* are most clearly advantageous in crude work. Inconvenient in precision work, they may still be needed in extreme cases. *The adiabatic method* avoids (1) several small lag effects, (2) much of the evapn. error and (3) the labor of certain calcns. and (4) furnishes a valuable alternative method. The notion that it diminishes the main thermal leakage errors is incorrect. (Cf. preceding abstract.) *Aneroid calorimeters* may advantageously be made as small as the experimenter can handle. There is always a gain in quickness and usually in precision. *The measured shield* is a convection shield of very thin metal around the calorimeter, supplied with thermoelements running to the jacket, which are used for the measurement of thermal head. It leaves the calorimeter quite free, and yet gives more than the advantage of thermoelements on the calorimeter. In some important ways it is more effective than vacuum jacketing.

WALTER P. WHITE.

**Combustion of an explosive gas mixture within a closed vessel.** L. FLAMM AND H. MACHE. *Akad. Wiss. Wien. Ber.* 126, 9-44(1917); *Sci. Abstracts* 21A, 269-70 (1918).—Calcns. are made relating to a spherical bomb containing combustible gas mixt. which is ignited exactly in the center. The most important data for the problems investigated are the rise of pressure in the bomb during the progress of the combustion and the temp. and sp. vol. of the combustion products. A formula is obtained which in the authors' opinion will afford a better interpretation of the exptl. results than those hitherto in use, owing to the smaller number of assumptions made. The question is investigated as to how far the important explosion method of Mallard and Le Chatelier for the estn. of the sp. heats of gases at high temps. needs correction on account of the temp. variations which arise after combustion commences. The relationship is examd. between the change of the combustion velocity of a gas mixt. and its initial temp. and pressure, whereby an insight is afforded into the mechanism of the combustion procedure within an explosion motor.

### 3. SUBATOMIC PHENOMENA AND RADIOCHEMISTRY.

GERALD L. WENDT.

System of radioactive elements. INGO W. D. HACKH. *Chem. Met. Eng.* 19, 751-2(1918).—A review, emphasizing the position of the radioactive elements in the periodic table. Cf. *C. A.* 12, 1607. G. L. WENDT.

Radium and radioactivity. CHAS. H. VIOL. Pittsburg. *Chem. Met. Eng.* 19, 752(1918).—An address. Nearly 2 oz. of high purity Ra have now been produced in this country. The U. S. Bureau of Mines estd. in 1914 that the total available Ra in the carnotite ores of the U. S. did not exceed  $3\frac{1}{2}$  oz., and asked for Government reservation of Ra lands. The standard Chem. Co. now estimates that at least 20 oz. of Ra can be prepd. from Colo. carnotite. G. L. WENDT.

Ionization of gases during chemical reactions. ALEXANDER PINKUS. Univ. Geneva. *Helvetica Chimica Acta*, 1, 141-5(1918).—An attempt to detect electron emission during gaseous chem. reactions, avoiding such physical causes of emission as incandescence, luminescence, spraying, etc. Ionization was detected by the increased rate of discharge of a bifilar electrometer in elec. connection with a charged Pt electrode sealed directly through the walls of a glass reaction bulb. The reaction  $2\text{NO} + \text{O}_2 = 2\text{NO}_2$  gave no ions. The total pressure varied from  $\frac{1}{4}$  to  $\frac{1}{2}$  atms. and the proportions of NO varied from 0.5 to 8 vols. per vol. of  $\text{O}_2$ . The reaction  $2\text{NO} + \text{Cl}_2 = 2\text{NOCl}$  gave no ionization unless the  $\text{Cl}_2$  was present in excess, and gave no marked ionization unless 2 vols. of  $\text{Cl}_2$  or more were present for each vol. of NO. The formation of  $\text{NOCl}$  is suggested, the decompn. of which may be the cause of ionization. G. L. WENDT.

Crystalloluminescence. II. HARRY B. WEISER. Rice Inst., Houston. *J. Phys. Chem.* 22, 576-95(1918); cf. *C. A.* 12, 2490.—The light emitted by crystals of  $\text{As}_2\text{O}_3$  and of  $2\text{K}_2\text{SO}_4 \cdot \text{Na}_2\text{SO}_4$  when crushed (triboluminescence) lies in the same region of the spectrum as the light emitted when these crystals are formed by rapid precipitation from soln. (crystalloluminescence). Both phenomena are attributed to the rapid reformation of mols., these having been broken up by the violent disruption of crystals in the one case, and by elec. dissociation in the other. Triboluminescence is the more common. All crystalloluminescent substances are triboluminescent. The intensity of triboluminescence varies widely in different substances. G. L. W.

**Types of phosphorescence.** EDWARD L. NICHOLS AND H. L. HOWES. Cornell Univ. *Proc. Nat. Acad. Sci.* 4, 305-12(1918); cf. *C. A.* 11, 1784; 12, 2163.—It was formerly assumed that curves of decay of phosphorescent bodies were all of the same type. Two different types have been shown by the authors to exist: (1) persistent phosphorescence which is made up of a succession of linear processes of diminishing slope proceeding from the origin of time, (2) vanishing type in which the linear processes are of decreasing slope. The location of the breaks is dependent on the intensity of excitation in the case of uranyl salts. In uranyl compds. and in Franklin Furnace calcite both types may be obtained, the vanishing under photo-excitation and the persistent under cathode discharge. The two types are entirely independent of each other, and calcite crystals after cathode bombardment *do not* show persistent curves when photo-excited. Willemite apparently shows both types with a single source of excitation, but this is probably due to the fact that there are two varieties, one of which is persistent under both excitations and the other vanishing under both. Either both types occur in the same sample or there is an admixture of calcite. Not all phosphorescence of quick decay is of the vanishing type, as is shown by the curves for  $\text{ZnCl}_2$ ,  $\text{CdCl}_2$ ,  $\text{CdSO}_4$  each mixed with  $\text{MnSO}_4$  and fused with  $\text{Na}_2\text{SO}_4$ . In the persistent type with short duration, the initial process may be very rapid, but if it does not go to the limit of visibility, the glow may persist for a considerable time. Cd phosphate exhibits a compound curve which is due to overlapping bands in the phosphorescence spectrum. Curves exhibiting the new type of vanishing decay resemble those obtained by infra-red excitation on Sidot blend. Here the application of infra-red rays hastens the decay, but in the other cases studied this could not be accomplished. Hence the successively steeper processes are probably due to a change in the rate of recombination of the ejected electrons with the active phosphorescing groups; or the sudden change may be due to a change in the electric field concomitant with the changed orientation of the charged particles, which drives the ejected electrons in greater proportion to the non-active portion of the mol. F. C. HORT.

**The photoluminescence and cathodoluminescence of calcite.** E. L. NICHOLS, H. L. HOWES AND D. T. WILBER. Cornell Univ. *Phys. Rev.* 12, 351-67(1918); cf. *C. A.* 12, 1263 and preceding abstract.—The characteristic ruddy phosphorescence of Franklin Furnace, N. J., calcites appears to be due to the presence of Mn.  $\text{CaCO}_3$  artificially prepared is rendered similarly phosphorescent by the addition of a Mn salt and subsequent heat treatment. This suggests that the luminescent centers are actually  $\text{CaO}$  with  $\text{MnO}$  or other oxide attached in a special manner. The phosphorescences under excitation by light from an Fe spark and by cathode-ray bombardment were quant. studied. The phosphorescence under photo-excitation is of the vanishing type, color ruddy, duration about 0.4 sec., and the decay curve shows three successive linear processes, a type which has heretofore been observed only with certain uranyl salts. The cathodoluminescence is persistent, measurable after 300 sec., red in color, and the decay curves are of the usual, *i. e.*, sulfide, type with a series of linear processes. The red and green regions of the spectrum are both affected by rising temp., the red attaining a max. intensity at about  $70^\circ$  and the green at about  $160^\circ$ , while both become too dim to measure at about  $350^\circ$ . Spectrophotometric measurements show two series of overlapping bands spaced equally in frequency units. The rate of decay of the phosphorescence is not affected by the application of red or infra-red radiation. The action of cathode rays does not render these calcites even temporarily capable of persistent phosphorescence under photo-excitation, but the vanishing photo-excited phosphorescence may be superimposed on the persistent phosphorescence of cathodo-excitation either during or after exposures to the cathode rays. G. L. WENDT.

**The mechanism of light emission.** E. P. LEWIS. *Sci. Monthly* 7, 97-111(1918).—A popular discussion of radiation in relation to theory of atomic structure. The respective difficulties facing the static type of structure proposed by J. J. Thomson and the kinematic "astronomical" atom proposed by Rutherford are clearly posed and critically examined. It is pointed out that the former is more consistent with chem., the latter with radioactive phenomena. S. E. SHEPPARD.

#### Bioluminescence (HARVEY) III.

**Solid radioactive preparation.** E. HEYDENREICH. U. S. 1,285,704, Nov. 26. A block of kieselguhr or similar porous material is formed with a cavity containing radio-Th and this block is placed in an acidulated weak soln. of NaCl to charge the liquid with emanation-producing material.

### 4. ELECTROCHEMISTRY.

COLIN G. FINK.

**The Wild-Barfield electric muffle.** ANON. *Engineering* 106, 143(1918).—This muffle is fitted with a pyroscopic detector and is designed for the heating of C steel parts to the proper hardening temp. The inner pot *A*, the muffle chamber, is of refractory material wound with a heating and magnetizing coil *B*. The outside casing of the muffle is wound with a coil of special enamelled copper wire which forms the detecting coil *E*, and is connected with terminals to the galvanometer circuit. The compensator is used to balance irregularities of voltage in the heating and magnetizing circuit, so that a clear and steady reading is obtained on the galvanometer. When a current is passed through *B*, the muffle becomes heated and magnetizes the steel inside. Since the best temp. for quenching C steel is at the point where it becomes non-magnetic, a small current is automatically induced in the winding *E*, when this point is reached, indicating to the operator that the temp. for quenching has been attained. The power consumption of a muffle, having an internal dimension of 12" × 4", is 1.4 kilowatt for 1000°. W. E. RUDER.

**Canada's heritage in the St. Lawrence River.** A. V. WHITE. *Elec. World* 72, 1216-7(1918).—The estimated low-water power aggregates 2,000,000 h. p. This is of particular interest to the electrochem. industries. A brief account of the various prospects is given. C. G. F.

**Electric steel furnaces in England.** F. J. MOFFET. *Elec. Rev.* 73, 1000(1918).—There were 140 elec. steel furnaces operating in England in 1917. About half of these are in the Sheffield and Rotherham districts. The Héroult furnace is most commonly used; next in order are Greaves-Etchell, Electrometals, Rennerfelt, and Stobie. The standard sizes of furnaces, with the transformer capacities and kw.-hrs. per ton of finished steel: 2800 lbs., 300 kw., 850 kw.-hrs. per ton; 2.5 tons (long), 500 kw., 800 kw.-hrs.; 5 tons, 800 kw., 750 kw.-hrs. At the Robert Hadfield works, Sheffield, the energy consumption in 1917 per ton of elec. steel was 782 kw.-hrs. based on a total production of 31,850 tons. C. G. F.

**The electrolytic deposition of iron from organic solvents.** E. H. ARCHIBALD AND L. A. PRIQUET. *Trans. Roy. Soc. Canada* 11, III, 107-12(1917).—A detailed report of 8 expts. in electrolysis of Fe solns. leads to the following conclusions: It is

possible to obtain complete deposition of Fe from solns. of  $\text{FeCl}_3$  in AcMe, and in AcMe and  $\text{H}_2\text{O}$ ; the Fe can be deposited entirely free from C. At low voltages the Fe is deposited in metallic form. As voltage is increased, the Fe comes down as a red deposit which adheres to the electrode, and allows the Fe to be removed from the soln. From solns. of  $\text{FeCl}_3$  in AcMe with EtOH, the Fe, although completely deposited, is contaminated with C. A soln. of  $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$  in 1 part AcMe and 2 parts  $\text{H}_2\text{O}$  electrolyzed using 0.1 amp. 100 sq. cm. at 4.7 v., deposited gray metallic Fe on Pt or Ag electrodes. Upon raising the voltage to complete the sepn. of the Fe the deposit became red as above, but the removal of Fe from the electrolyte was complete. A similar soln. was prepared and 1 g.  $(\text{NH}_4)_2\text{SO}_4$  added, in order to lower the high resistance. This was then electrolyzed at 4.0 v. and current density 0.1 amp./100 sq. cm. As the electrolysis continued, the acidity of the soln. increased and it was found necessary to neutralize a part of the acid from time to time by adding  $\text{NH}_4\text{OH}$ . All the Fe was obtained as gray, adherent, weighable, metallic Fe. No  $\text{AcH}$  is formed during the electrolysis. It is thought that these facts could be used as a basis for the sepn. of Fe from other metals such as Al and Cr.

H. M. LANCASTER.

**The electrolytic precipitation of zinc.** D. MCINTOSH. *Trans. Roy. Soc. Canada* 11, III, 113-9 (1917).—This article, including 19 pages of plates showing photographs of electrolytic deposits obtained under various conditions, is not intended to present anything new to those who have worked on the pptn. of Zn, but contains many points of interest to those unfamiliar with the process. The exptl. work was carried out at Trail. Portions of about 2500 cc. of a soln. containing 4.0-5.0% Zn were electrolyzed between Pb anodes and Al cathode with a c. d. of 20-30 amp. per sq. ft. In general, the electrolysis was continued until the Zn had been brought to about 0.5%, the acid increasing to 6-7%. Various impurities were added before electrolysis, and the effect noted. In order to secure good deposits the following conditions should be observed: The soln. should be absolutely clear and free from colloids. The Fe should be low. As, Sb, Cu, Co, Ni and in general, metals more electropositive than Zn must be absent. The soln., particularly in tanks containing large amts. of acid, should be cold. The Zn deposits in a semi-passive form, but when it begins to dissolve, soln. cannot be stopped in any simple way. The concn. of the Zn should be as high as possible (6-7%). No attempt should be made to electrolyze a soln. containing less than 2.0-1.5% Zn. With the ordinary cascade system the optimum c. d. is 25-30 amps. per sq. ft. H. M. L.

**Resistance of pure insulating materials.** E. POPEZUS. *Verh. deut. physik. Ges.* 19, 231 (1918); *Elektrotechn. Z.* 39, 229 (1918).—A W ribbon 1 mm. wide and 0.2 mm. thick was wound into a helix 28 mm. long and 7.5 mm. in diam. The helix was mounted on the stem of a large incandescent lamp bulb and the ends of the ribbon were attached to the leading-in wires. Current of 50 cycles was passed through the ribbon and temp. measurements were made with a Holborn-Kurlbaum pyrometer.  $\text{CaO}$ ,  $\text{Al}_2\text{O}_3$ ,  $\text{MgO}$ ,  $\text{ThO}_2$  and BN were compressed into small pencils 10 mm. long by 1.3 mm. diam., connected with a Wheatstonebridge and suspended in the W helix. The bulb was then evacuated. BN had the highest resistance at incandescent temp. The introduction of N into the bulb caused the resistance (temp. = const.) to drop with all oxides, except  $\text{Al}_2\text{O}_3$ .

C. G. F.

**The design of porcelain insulators from the ceramic standpoint.** G. I. GILCHRIST AND T. A. KLINEFELTER. *Elec. J.* 15, 443-5, 489-92 (1918).—G. and K. found that quality is detd. by the kind of blanks, method of handling the clay and throwing into molds, general speed in working, and the accuracy of the machines. Abrupt changes in thickness and sharp corners increase the liability to crack, and in glazing, the surface tension of the glaze pulls it away from sharp edges and floods abrupt corners. In baking, the most trouble develops from too small a placing surface, with attendant

breakage. Thick walls and thin central holes should be avoided and corrugations made not too thin nor too deep. From a theoretical standpoint, a conception was formed of the functions which air and solid dielectrics perform when used in combination for insulating purposes. Based on this conception, a large number of tests were made under commercial conditions, which show that it is possible to use air more efficiently than has been customary in the past. Breakdowns of an air path over a surface were obtained which average as high as 9.4 kv. per cm. effective value (23,900 volts per in.) over a distance of 17.0 cm. The conditions of design are such that these same averages may be maintained at any voltage by increasing all dimensions of the structure proportionately. A max. efficiency of air path over a surface was obtained when the surface of the dielectric is made to conform to the flow lines between the terminals. The strength of such a path is independent of the specific inductive capacity of the dielectric. The principal thing to be considered, therefore, is the proper shaping of the terminals in order that points of high intensity may be eliminated and a high av. intensity obtained for the given path.

C. G. F.

**Graphs for finding safe current-carrying capacity of insulated wire.** M. C. MASON. *Elec. Rev.* 73, 1020 (1918).—Two graphs are shown, based on the National Electric Code rule No. 18.

C. G. F.

The electrochemical investigations of Prof. Dr. E. Cohen (HELDERMAN) 2. Constitution and thermal stability of carbides (RUFF, *et al*) 6.

**Storage battery.** J. P. MENTZER. U. S. 1,285,303, Nov. 19. Storage battery separators are formed of kieselguhr mixed with  $\text{CaSO}_4$  and fibrous material.

**Storage-battery.** B. FORD. U. S. 1,285,658, Nov. 26. Structural features.

**Storage-battery.** B. FORD. U. S. 1,285,660, Nov. 26. Structural features.

**Galvanic battery.** H. A. STOFFLET. U. S. 1,285,831, Nov. 26. Structural features.

**Electric battery.** H. F. FRENCH and R. C. BENNER. U. S. 1,285,054, Nov. 19. Elec. batteries are formed with a Zn electrode and an electrolyte of  $\text{NH}_4\text{OH}$  and  $\text{NaOH}$  or  $\text{KOH}$  soln. The  $\text{NH}_4\text{OH}$  retards formation of crystals on the Zn electrode.

**Electroplating apparatus.** L. POTTHOFF. U. S. 1,285,369, Nov. 19.

**Electroplating apparatus.** J. E. WOODBURY. U. S. 1,285,875, Nov. 26.

**Electrolytic condenser.** R. D. MERSHON and J. S. RIDDILE. U. S. 1,285,305, Nov. 19. Film-coated Al electrodes of electrolytic condensers are wholly submerged in the electrolyte and are connected to the external circuit by filmed Al connecting devices attached to alternate electrodes and extending outside the electrolyte. This construction prevents attack on the electrodes at the surface of the electrolyte.

**Electrochemical reduction of ores and salts.** A. A. M. HANRIOT. U. S. 1,285,690, Nov. 26. The metallic components of materials such as  $\text{AgCl}$ , galena, malachite or cinnabar are obtained by placing the material in contact with the cathode in an electrolytic bath and passing an elec. current through the bath, using such a voltage that the metallic element, *e. g.*, Ag, Pb, Cu or Hg, will be converted into pure metal at the cathode and that a non-metallic constituent, *e. g.*, Cl or S, will be collected at the anode.

**Electric furnace.** B. RAEDER. U. S. 1,286,100, Nov. 26. The furnace is especially adapted for the production of Zn.

**Depositing clay, plumbago, or the like on molds.** B. J. ALLEN. Can., 185,733, July 30, 1918. The material is introduced in a liquid state into an absorbent mold and an elec. current is passed through the material between an electrode suspended therein and one in contact with the outer face of the mold.

**Electric furnace for refining zinc.** S. HULDT. Can. 187,865, Dec. 10, 1918. The furnace comprizes a chamber having an inlet opening communicating with the bottom, a vapor outlet at the top thereof, a feed receiver communicating with the inlet opening and adapted to retain a portion of the molten bath for closing the opening and a feed opening in the wall of the chamber.

**Production of cyanogen compounds.** A. R. LINDBLAD. Can. 187,728, Dec. 3, 1918. An alkali silicate with a reducing agent and lime is charged into an elec. furnace in the presence of N and heated to form cyanogen compds., which are removed from the furnace.

**Refining volatile metals.** S. HULDT. Can. 187,864, Dec. 10, 1918. Metal to be refined is fed into an elec. arc furnace through a liquid trap formed by said metal, so as to maintain a metal bath in the furnace bottom; the surface of the bath is exposed to heat from the arc and the metal vapors are removed and condensed.

**Accumulator electrode grids.** S. WILLNER. Can. 187,774, Dec. 3, 1918. The grid has a series of upright bars and a series of horizontal bars integral therewith and crossing the same so as to form spaces enclosed by two bars of each series, each bar where it forms a boundary between two of the spaces being perforated to give communication from one space to its neighbor.

**Mercury-vapor rectifier.** S. W. FARNSWORTH. U. S. 1,285,965, Nov. 26. A vapor converter with a Hg cathode and anodes of solid material is operated with a vacuum of less than 0.002 mm. Hg by passing load current through the app. while maintaining the anode at a temp. of 80-100°. This temp. regulation results in increased efficiency. U. S. 1,285,966 and 1,285,967 relate to structural features of vapor elec. converters.

## 5. PHOTOGRAPHY.

---

LOUIS DERR.

**Coloring materials in the photographic industry.** A. SEYEWETZ. *Chimie & industrie* 1, 492-500(1918).—There are dyes which sensitize the photographic plate to rays differing from those which the dyes absorb in soln., from which it may be concluded that the sensitizing power lies in the Ag-dye compd. analogous to a lake. The principal classes of sensitizing dyes are derivs. of di- and triphenylmethane, acridine, phenylacridine, and quinoline. For sensitizing for green and yellow, the phthaleins are the most important, in particular eosin, erythrosin, and rose Bengal. For yellow and orange, quinoline red, the rosaniline violets, especially ethyl violet, and the cyanines are used. For orange and red, the blue lepidine-cyanines are available, carrying the sensitiveness to the C-line of the spectrum; and, for red-sensitizing, the König series of orthochrome T, pinachrome, pinaverdol, homocol, ethylcyanine, pinacyanol, and dicyanin, carrying the sensitiveness to the B-line without undue blue-sensitiveness. For a non-halation backing, to be placed between the emulsion and the support and decolorized for subsequent printing, rosolic acid and Congo red are among the few known dyes suitable. For 3-color filters, methylene blue is suggested for the blue, a mixt. of erythrosin and metanile yellow for the orange, and a mixt. of methylene blue

and auramine for the yellow. For the red-blue-yellow colors of positives, erythrosin J, chrysophenine A, and pure diamine blue are named. The Traube process is based on the power of AgI to fix a large number of acid and basic dyes, such as methyl violet, ethyl green, quinoline red, rhodamine, eosin, auramine, methylene blue, and others. For processes involving the leucobases, reassuming color under the impact of light, *o*-chlorotetraethyl-diaminotriphenylmethane is used for blue, the leucobase of malachite green for green, *p*-leucaniline or the leuco-rhodamines for red, hexamethyl-*p*-leucaniline for violet, and leuco-fluoresceine or leuco-flavaniline for yellow; the fixing is by monochloroacetic acid. For the bleach-out processes, methylene blue, auramine, and erythrosin in gelatin, sensitized by  $H_2O_2$  are used; but primrose, Victoria blue, cyanine, curcuma, and auramine, sensitized by anethol, are better; these processes are, however, imperfect. L. DERR.

**New photographic mordant dye process.** F. E. IVES. *J. Frank Inst.* 186, 755-7 (1918).—The so-called "mordant-dye" process of producing colored prints, introduced by Traube, depends on the conversion of the Ag image into AgI, which becomes strongly colored by immersion in basic dyes. The dye is fixed by tannin, the AgI dissolved out, and a transparent dye-image is left. Ag ferrocyanide and chromate and other Ag salts can be similarly dyed, but not well; but a Cu-toned image possesses the same property to a most useful degree (*C. A.* 12, 2170). A new mordant is described, a Cr compd. of nature undetd. It is produced by bleaching the image in a soln. of equal parts of 1.5% KCN and 1.5% chromic acid, washing out the free acid after bleaching, preferably in water contg. a little  $NaHCO_3$ . A typical dye-bath is 0.3 g. safranin in 115 cc. alc., adding 1 l. water slightly acidified with AcOH. After immersion, which may require 30 min., the film may be cleared from surplus dye by a wash in water contg. a very little AcOH. Other very active dyes are malachite green and auramine. L. D.

**Color photography.** HESS-IVES CORPORATION. *Brit.* 119,854, June 7, 1918. In the production of multi-colored photographs or cinematograph films, two colored images are produced by exposure, etc., on opposite sides of a colloid layer supported on a base; one image may be a Cu-toned Ag image or a Cu-toned and mordant-dyed Ag image, and the other image may be a cyanotype image. The first image may be printed on to a colloid layer sensitized with a Ag halide, and through the base supporting it, from a green-representing negative, and after development, etc., of the image, the colloid layer may be resensitized in a 2% bath of green citrate of Fe and  $NH_4$ , blotted off, and dried. The other surface of the layer is then exposed under a red-representing negative and the image is developed with a 1% soln. of  $K_4Fe(CN)_6$ , the two images being confined largely to their respective sides of the colloid layer. The Ag image is next converted into a red pigment image by means of a Cu toning bath and may be fixed with  $Na_2S_2O_4$ , or the toning may be performed before the second sensitizing. The color of the red image may be modified or intensified by treatment with a basic dye such as fuchsine or auramine, which is mordanted by the Cu image, and the color of the cyanotype image may be modified by the addition of a reagent such as  $K_2Mn_2O_8$  to the developer, or by treatment after development with a dil., slightly acid, soln. of  $K_2Cr_2O_7$ . A third colored image may be combined with images prepd. as above set forth.

## 6. INORGANIC CHEMISTRY.

H. I. SCHLESINGER.

**Constitution and thermal stability of carbides.** OTTO RUFF, E. JELLINEK AND T. FORER. *Breslau. Z. Elektrochem.* 24, 157-62 (1918).—Expts. were carried out in an

elec. furnace of the Arsem vacuum furnace type, having a C resistor. In the first expts., a pressure less than 3 to 5 mm. was not attainable; the residual gases N, H and CO, brought about a "transfer" of C from the incandescent resistor tube to metals, oxides, etc., under investigation: *e. g.*, incandescent  $C + 2H_2 = CH_4$  and then  $CH_4 + M = MC + 2H_2$  where M represents the metal. W is thus readily transformed into carbide and the m. p. of the metal drops from  $3200^\circ$  down to  $2650^\circ$  (corresponding to a W-C alloy with 0.8% C) within a few seconds. To retard, or entirely to prevent the formation of carbides, argon gas was introduced into the vacuum furnace (Ger. patent 295,050, Nov. 26, 1915). Expts. on the formation of carbides lead to the conclusion that metal carbides, in general, are stable up to temps. above  $2500^\circ$  and that even at these elevated temps. C does not dissolve in the metals as such, but as a carbide of the metals. *Al + C series:* Liquid Al dissolves but little C, but readily forms the solid carbide  $Al_4C_3$ . It is very difficult to produce  $Al_4C_3$  free from N. The existence of a second carbide,  $Al_3C_2$ , appears very probable. At pressures below 400 mm.  $Al_4C_3$  volatilizes without melting; at about 400 mm. and  $2200^\circ$  the carbide fuses with partial decompn. into graphite and Al. Pure Al metal was heated in a graphite crucible in H at 1 atm. at various temps. When heated to temps. below  $2200^\circ$ ,  $Al_4C_3$  was formed; when heated at  $2200^\circ$ ,  $Al_4C_3$  plus Al was formed and when heated above  $2200^\circ$ , graphite alone remained. At  $2270^\circ$  the Al carbide vapor was found to contain 13.3% to 14.1% C (vapor pressure curve is shown). *The Cr + C series:* At about  $1900^\circ$  Cr dissolves 12% C; with rising temps. the soly. increases at first very slowly up to about  $2250^\circ$  ( $Cr_3C_2$ ); above this temp. the soly. increases more rapidly (formation of  $CrC$ ?). At a temp. of  $1400^\circ$  the carbide  $Cr_3C_2$  seps. out. All of the Cr carbides were insol. in cold 2 N HCl (in the absence of air) whereas Cr metal was sol. (etching of metallographic sections).  $Cr_3C_2$  is insol. in hot concd. HCl but the lower carbides are sol. The b. p. of Cr satd. with C is  $2270^\circ$ . The stable satd. carbide of Mo is  $Mo_2C$ . To date, the known metal carbides conform with the following hydrocarbons:  $CH_4$ ,  $C_2H_6$ ,  $C_2H_4$ ,  $C_2H_2$  and  $C_4H_{10}$ . The valency of the metal in the carbide is usually lower than that commonly assumed. The heavy metals generally form monocarbides. In the case of most metals, the C concn. increases with increasing temp., *e. g.*,  $W_3C$ ,  $W_2C$ ,  $WC$ . Within wide temp. limits carbides such as  $Mn_3C$ ,  $Cr_3C_2$  and  $W_3C$  are very stable; carbides such as  $Fe_3C$ ,  $WC$  and  $Cr_3C_2$  decompose upon lowering the temp. to the m. p. of the alloy into metal plus C.  $Fe_3C$  is hard to obtain in the solid phase and  $Ni_3C$  is altogether unstable as solid. All carbides dissociate more or less completely upon volatilization. The more electropositive a metal, the more stable its carbide: upon vaporizing  $Fe_3C$  is almost completely dissociated;  $Al_4C_3$ , however, is only partially dissociated.

## 7. ANALYTICAL CHEMISTRY.

E. G. R. ARDAGH.

Thymolphthalein as an indicator in the acidimetry and alkalimetry of dark solutions. D. HOLDE. *Chem. Umschau Fette, Oele, Wachse u. Harze* 25, 73(1918).—Thymolphthalein is described. A few drops of a 1% soln. in alc. are sufficient to give the change from colorless to blue by the least excess of alkali. H. has made some assays of dark oils using thymolphthalein; in some of these the change of color could be easily observed, especially by running down the benzene or ether-alc. soln. along the sides of the flask. Naturally a mixed color also arises from the usually brown

to the red-black coloration of the dark oils or soap solns., which is to be taken into consideration.

TH. VERHEGGEN.

**Determination of carbon in steel and ferro-alloys, especially in ferrochrome.** P. KOCH. *Stahl u. Eisen* 38, 219-21(1918).—Since elec. resistance furnaces have been introduced into the labs. of the iron-works C is detd. in iron and steel and in the ferro-alloys by direct combustion in an O current. The principal conditions to be obtained in this process are the complete combustion of the C into  $\text{CO}_2$  and, in the case of material rich in S, the avoidance of harm from generated  $\text{SO}_3$  or  $\text{SO}_2$ . The temp. of the furnace should not be less than  $1000^\circ$  and it must remain below the fusion point of the metal being examd.; if not the metal would melt before being completely decarburized, and if the temp. is too high the  $\text{CO}_2$  will be dissociated into  $\text{CO} + \text{O}$ , and the  $\text{FeSO}_4$  formed may also be decomposed with evolution of  $\text{SO}_2$  or  $\text{SO}_3$ . To make  $\text{SO}_2$  harmless, chromic acid or  $\text{PbO}_2$  are used. For normal amounts of S this is hardly necessary. A complete oxidation of C is best obtained while operating upon fine shavings. Cr steel and Ni steel, poor in C, are oxidized with more difficulty; the best condition for combustion is a high temp. in O under feeble pressure. Sometimes it is necessary to add an oxidizing agent to the metal to be examd., this is the case with ferro-chrome to which is added Bi trioxide. Co oxide is also a good oxidizing agent. The author describes in detail both gravimetric and volumetric methods for the detn. of C in ferro-chrome.

TH. VERHEGGEN.

**Tungstic and molybdic compounds as precipitating reagents for certain basic organic compounds.** LUIS GUGLIAMELLI. *Anales soc. quim. Argentina* 6, 57-64. —G. studied the reactions of the following compds. of W and Mo on a no. of pyrazole, purine, quinoline and pyridine bases (also amino-imine bases of diphenyl-methane): (1) Na tungstate—1% aq. soln.; (2) arsenotungstic reagent—prepd. by adding 10 g. Na tungstate and 25 g.  $\text{As}_2\text{O}_3$  to 100 cc.  $\text{H}_2\text{O}$  and boiling under a reflux condenser for 2 hrs.; (3) silicotungstic reagent—10% soln. prepd. according to Copaux; (4) phosphotungstic reagent—prepd. by dissolving 100 g. Na phosphotungstate in 100 cc. of 5% aq. HCl; (5) Na molybdate soln. of 100 g. of the salt in 100 cc. of 5% aq. HCl; (6) arsenomolybdic reagent—prepd. in the same manner as (2), the tungstate being replaced by molybdate; (7) phosphomolybdic reagent—10 g. of phosphomolybdic acid in 100 cc. of 5% aq. HCl; (8) arsenotungstomolybdic reagent—prepd. by boiling for 2 hrs. under a reflux condenser a soln. containing 10% Na tungstate, 1% Na molybdate and 25%  $\text{As}_2\text{O}_3$ ; (9) arsenovanadotungstic reagent—prepd. same as (8), Na molybdate being replaced by Na vanadate. The above reagents were also tested in comparison with Mayer's reagent. In making the tests 1 cc. of the reagent was added to approx. 5 cc. of the soln. of the organic base. Varying results were obtained and no general rule could be formulated. (1) gave distinct ppts. with 1:1000-2500 solns. of quinoline and a 1:2500 soln. of cinchonine, but gave no ppt. after 24 hrs. with 5% solns. of  $\text{C}_6\text{H}_5\text{N}$  and nicotine. (2) pptd. all the bases except caffeine, (3) pptd. caffeine but not  $\alpha$ - and  $\beta$ -naphthylamine and  $\text{C}_6\text{H}_5\text{N}$ . (4) gave no ppt. with cocaine. (5) in spite of its similarity to (1) reacted somewhat differently; it gave no ppt. with cocaine, quinoline and  $\alpha$ - and  $\beta$ -naphthylamine, (6) pptd. only cinchonine. (7) was an excellent general precipitant and produced ppts. of general crystalline appearance in very dil. solns. (8) behaved the same as (2). (9) gave no ppt. with caffeine, antipyrine and pyrazidone. Practically all of the above reagents, especially (2) and (7) were fully as efficient general precipitants as Mayer's reagent. The following bases were tested with the foregoing reagents:  $\alpha$ -naphthylamine,  $\beta$ -naphthylamine, benzidine, antipyrine, pyrazidone, pyridine, nicotine, quinoline, cinchonine, caffeine, cocaine, auramine. The results obtained in each case are shown in detail in tabulated data.

H. S. PAINE.

**New sensitive reaction for pyrimidone and its differentiation from antipyrine.** LUCIANO P. J. PALET. *Anales soc. quim. Argentina* 6, 151-5(1918).—An aq. soln. of pyrimidone treated with several drops of a freshly prepd. aq. soln. of  $K_3Fe(CN)_6$  and  $Fe_2Cl_6$  gives a characteristic blue color and ppt. of Prussian blue; the reaction is very sensitive. Pyrimidone may thus be clearly differentiated from other organic compds. which accompany it in various therapeutic preps. For instance, the  $K_3Fe(CN)_6$ - $Fe_2Cl_6$  reagent gave a blood-red color and ppt. with antipyrine, a violet-red color with salipyrine and a negative reaction with phenacetine, acetanilide, aspirin, exalgin and caffeine. When pyrimidone and antipyrine are both present a poorly defined dark color due to mixt. of the colors of the 2 reactions is produced. This may be obviated by adding HCl; the blood-red color and ppt. due to antipyrine then changes to a light yellow color and the blue color due to pyrimidone persists. Traces of pyrimidone may thus be detected in the presence of a great excess of antipyrine. The reaction given by other reagents with (1) pyrimidone and (2) antipyrine, resp., are as follows: Guglielmelli's arsenotungstic reagent—(1) white ppt. sol. in alkali with intense blue color, (2) white ppt. sol. in alkali without coloration; Guglielmelli's arsenotungstomolybdic reagent—(1) white ppt. sol. in alkali with indigo blue color, (2) white ppt. sol. in alkali without coloration;  $Fe_2Cl_6$ —(1) red color changing to yellow after action of  $H_2SO_4$ , (2) violet-blue color practically unaffected by  $H_2SO_4$ ;  $NaNO_2$  and  $AcOH$  or  $H_2SO_4$ —(1) transient amethyst-violet color, (2) bluish green color changing to blood red after boiling with  $HNO_3$ ;  $H_2SO_4$ ,  $NaNO_2$  and  $NH_4OH$ —(1) violet color which disappears after addition of the  $NH_4OH$ , (2) intense green color which persists after addition of the  $NH_4OH$ ;  $AgNO_3$ —(1) intense blue color which changes to violet with deposition of reduced Ag, (2) no color change (soln. colorless); HCl, HCHO and  $NH_4OH$ —(1) no color change (soln. colorless), (2) white ppt.; soln. of gum arabic in the cold and with aeration—(1) violet-blue color, (2) no color change; alfalfa roots and  $H_2O_2$ —(1) violet color, (2) no color change.

H. S. PAINE.

**Action of the potassium ferricyanide and ferric chloride reagent on alkaloids, glucosides and other plant constituents.** LUCIANO P. J. PALET. *Anales soc. quim. Argentina* 6, 156-8(1918).—P. tested the action of the  $K_3Fe(CN)_6$ - $Fe_2Cl_6$  reagent (cf. preceding abstract) on 102 plant constituents. A positive reaction was given by the following alkaloids: apomorphine, beberine, berberine, brucine, codeine, colchicine, curarine, emetine, sparteine, erythrofeine, physostygmine, hydrastine, morphine, meconine, napeline, narcotine, pelletierine, pseudopelletierine, pereirine, sabadilline. A positive reaction was obtained with the following glucosides: adonidin, apocinin, arbutin, apiin, boldin, convalamarin, esculin, strophanthin, smilacin, floridin, globularin, graciolin, helleborin, hesperidin, sabatin, salicin, sapotoxin, siringuin. A positive reaction was obtained with the following bitter principles: aloin, *cotoina verum*, scoparin.

H. S. PAINE.

**Rapid detection of morphine in the chemico-toxicological analysis of viscera.** LUCIANO P. J. PALET. *Anales soc. quim. Argentina* 6, 349-51(1918).—P. reports excellent results with the following modified Flückiger procedure for the rapid detection of small amts. of morphine:  $MgO$  was added to 120 g. viscera so as to form a somewhat stiff paste which was then heated to dryness on a  $H_2O$  bath. The well pulverized residue was then heated to boiling with  $Me_2CO$  (in a Soxhlet extractor if desired) and to the  $Me_2CO$  filtrate were added 2-3 cc.  $H_2O$  and several drops  $AcOH$ ; this mixt. was filtered and evapd. to dryness. This residue which contains the morphine with impurities is purified by adding 5% of  $AcOH$ , filtering and extg. the morphine from the filtrate by rendering it alk. with  $NH_4OH$  and using boiling  $CHCl_3$  as solvent. If the viscera are obtained from a cadaver in advanced stage of decompn. the  $CHCl_3$  residue should be purified by the Schaer method (using chloral hydrate).

In most instances very pure residues permitting the rapid detection of morphine or its derivs. are obtained. Regardless of the color reactions which may be employed the Marquis reaction which permits detection of oxymorphine should never be omitted in view of the possible oxidation of morphine in the kidneys. This method has been successfully applied to detection of small amts. of morphine in the case of death suspected to have been caused by small doses of laudanum.

H. S. PAINE.

**Distinction between different abrasives and the detection of carborundum in them.**

R. PETERS. *Pharm. Zentr.* 58, 217-9, 231-4(1917); *J. Soc. Chem. Ind.* 37, 335A.—Artificial corundum has a deeper grayish blue color than natural emery. It is distinguished from emery by the presence of microscopic inclusions of gas and is also less magnetic. It can be detected by heating the previously ignited sample with 20 parts of  $\text{PbCrO}_4$  in a hard glass tube; the mass becomes red hot with liberation of  $\text{CO}_2$ ; this will detect as low as 5%. For the detn. of small amts. it is necessary to treat the residue insol. in fused  $\text{KHSO}_4$  repeatedly with  $\text{HF}$  and  $\text{H}_2\text{SO}_4$  until a const. wt. is obtained. When small amts. of carborundum are present, the C may be detd. by heating the previously powdered and ignited sample with  $\text{KClO}_3$  and  $\text{PbCrO}_4$  in a current of air for about 1 hr., the  $\text{CO}_2$  being absorbed in  $\text{Ba(OH)}_2$  soln. after successive washings with  $\text{AgNO}_3$  and  $\text{FeSO}_4$  solns.

## 8. MINERALOGICAL AND GEOLOGICAL CHEMISTRY.

EDGAR T. WHERRY AND J. H. BOWER.

**Mineralogy of the H. B. Mine, Salmo, B. C.** T. L. WALKER. Univ. Toronto. *Studies* (Geol. series), No. 10, 25 pp.(1918).—The occurrence, crystallography, physical properties and chem. compn. of the minerals of this deposit are described in detail. Some of the data have been previously published (cf. *C. A.* 11, 433, 1389, 2570). The new matter includes analyses of calamine, parahopeite and a clay high in Zn. It is pointed out that 5 distinct phosphates of Zn are now known, and from the chem. point of view all of them are remarkable for their unusual purity and absence of isomorphous replacements. The source of the P entering into the compn. of the minerals at this mine is considered; it is believed to have been a phosphatic bed in the Carboniferous strata of the region.

E. T. W.

**Notes on the origin of colerainite.** EUGENE POITEVIN. *Trans. Royal Soc. Canada* [3] 12, 37-9(1918).—When first discovered colerainite was thought to be of secondary pneumatolytic origin, that is, formed by the action of the magmatic fluids accompanying the intrusion of pegmatite or aplite. Field observations have now shown that the dikes carrying the colerainite do not contain any characteristic products of secondary pneumatolysis, but do contain mica and other primary minerals incapable of withstanding the solvent action of magmatic fluids. Further, the colerainite is limited to the portions of the dikes which have been subject to the influence of surface waters, and is there associated with kaolinite, porcellophite, and aphrodite, all secondary minerals. It is, therefore, believed that the colerainite has been formed in the pegmatite dikes as a result of interaction between the Al minerals of the dikes and Mg salts carried down by surface waters, a possible reaction being:  $2\text{NaAlSi}_3\text{O}_8 + \text{CO}_2 + 4\text{MgO} + 5\text{H}_2\text{O} = 2\text{H}_2\text{Mg}_3\text{AlSiO}_5 + \text{Na}_2\text{CO}_3 + 4\text{SiO}_2$ .

E. T. W.

**The Alsace potash deposits and their economic significance in relation to terms of peace.** PAUL KESTNER. *J. Soc. Chem. Ind.* 37, 291-97(1918).—A rich deposit of potash was discovered in 1904 in southern Alsace, consisting of 2 beds, each 4 m. thick, underlying an area of 200 sq. kilometers. The deposit represents more than 300 million tons of salts of great purity, composed chiefly of sylvite. Previous to the war, the output was carefully controlled by the Kali Syndicate in favor of the Stassfurt deposits. While Germany possesses Alsace she has the monopoly of potash, and to insure peace, and save the world from German economic dominance, it is indispensable that Alsace should again become French. The deposits of Stassfurt, and minor ones in Galicia, Spain, Italy, Tunis, the United States, and Chile, are noted, with some statistics of the production and consumption of potash. S. G. GORDON.

**Communications from a lead-works.** D. A. LANDSBERG. *Metall u. Erz* 15, 27-8(1918).—The use of Zn to concentrate the Ag and Au occurring in a bath of Pb into a small quantity of alloy also effects the recovery of Pt and the Pt metals, of which traces occur sometimes in the treated ores. From the alloy obtained, Ag-Au-Pt, the Pt can be recovered after distn of the Zn. T. VERHEGGEN.

**Balanced reactions in steel manufacture.** ANDREW McCANCE. *Trans. Faraday Soc.* (advance copy), 11 pp.(1918).—The important reactions of steel making are re-

versible in nature and the laws developed by physico-chem. study of equilibrium conditions have an important bearing upon practical work. In this paper, an attempt is made to apply these principles to the theory of reactions that take place in the open-hearth furnace during the manufacture of steel. During the melting period, the higher the av. temp. the less oxidation of the scrap and less FeO in the slag. The dominant reaction during this period, and the one to be avoided, is  $3\text{FeO} + 4\text{H}_2\text{O} \rightleftharpoons \text{Fe}_3\text{O}_4 + 4\text{H}_2 + 38.5 \text{ cal.}$  The reaction, being exothermic, takes place less and less as the temp. is raised. The steam content of the combustion gases should be kept as low as possible. After melting, the liquid metal is covered with slag and during the boiling period, after the Si and Mn have been oxidized by the slag, the C in the original metal is oxidized by the FeO in the slag:  $\text{FeO} + \text{C} \rightleftharpoons \text{CO} + \text{Fe} - 35.6 \text{ cal.}$  The escape of the CO causes the boiling. The reaction takes place throughout the whole mass of metal. The *partition law* governs the distribution of the FeO between 2 solvents—molten metal and molten slag. As ore is added to the slag, FeO dissolves in the latter and is transferred to the metal in proportion as the FeO is used up by reaction with C. Toward the end of the operation, the addition of CaO lessens the soly. of FeO in the slag and thus forms a greater proportion of FeO being taken up by the metal. It would work unfavorably if CaO were added too soon, by lessening the supply of FeO. An increase of temp. from  $1550^\circ$  to  $1600^\circ$  reduces by more than by one-third the quantity of FeO dissolved in the molten metal and this is favorable toward the end of the boiling as it prevents slag inclusions in the finished steel. This effect is traced to the change in the equilibrium constant of the above reaction with rise of temp. As regards the reduction of Si from a highly siliceous slag, the reaction is accomplished by C rather than by Fe:  $\text{SiO}_2 + 2\text{C} \rightleftharpoons \text{Si} + 2\text{CO} - 122 \text{ cal.}$  The presence of CO in the molten metal entails a further reaction with FeO:  $\text{FeO} + \text{CO} \rightleftharpoons \text{Fe} + \text{CO}_2$ . A lowering of the temp. of working greatly decreases the ratio of  $\text{CO}:\text{CO}_2$  in the metal. If steel has a greater soly. for CO than for  $\text{CO}_2$  all the peculiarities in the relation of these gases and steel can be explained. If there is much FeO in soln., the ratio of  $\text{CO}_2:\text{CO}$  will be large and when the steel solidifies blow holes will form at the instant of solidification. At the finishing temp. the steel is satd. with CO.

**Soldering and brazing.** P. W. BLAIR. *Metal Ind.* 16, 547-9(1918).—"A practical article."

E. J. C.

**Rapid recrystallization in deformed non-ferrous metals.** D. HANSON. *J. Inst. Metals* (advance copy), 5 pp.(1918); *Engineering* 106, 403-4(1918).—For these expts. a device adopted by Chappel has been used. A test piece tapered towards the center, after being annealed, is broken in tension. In this way varying degrees of deformation are obtained, the maximum at the point of fracture down to zero at a point between the fracture and shoulder. A tapered test piece of cold-rolled Al, 0.1 in. thick, was annealed at  $480^\circ$  and broken cold. One-half was then re-annealed at  $480^\circ$  and quenched in water. On etching with HF, remarkably coarse crystals were found where the strain was least and from this region the crystal size decreased to the point of fracture. At the shoulder where the piece was not strained, or at least not enough to cause recrystn., the original crystal size was found. The other half of the test piece was annealed for 5 min. at  $450^\circ$ . Coarse crystals developed, but for a smaller distance from the point of fracture, and there was the same variation in size as with the other half. The same phenomena were observed with Mg, Pb and Cu, and in alloys consisting of solid solns. as Cu-Zn-Al alloy, and 70:30 brass. Apparently the following law is applicable to all strained metals: For every degree of deformation there is a critical recrystallization temp. at which crystal growth is extremely rapid. The size of crystal thus produced is greater as the deformation is less. The rate of increase in size of newly formed

crystals with prolonged time and increased temp. of annealing is small compared with their rate of growth at the critical temp. W. T. H.

**Carbon in cast iron.** FRANK H. KINGDON. *Iron Age* 102, 1439(1918).—The rapid detn. of total C by direct combustion and of graphitic C after treatment of the metal with dil.  $\text{HNO}_3$  is described. The use of the pyrometer to control the temp. is advocated. E. E. RICHARDSON.

**Solders for aluminium.** PAUL D. MERICA AND LOUIS J. GUREVICH. *Metal Ind.* 16, 500-3(1918).—Al can be welded satisfactorily by the O-gas process. The solders for Al usually contain Zn, Sn and Al in various proportions and are applied to surfaces that have been cleaned and "tinned" by coating with a layer of solder rubbed into the hot surface. Fluxes may be used consisting of stearic acid, rosin,  $\text{ZnCl}_2$ , soap, sugar, or mixtures of these substances. Data are given showing tests of the strength, ductility and electrolytic behavior of various solders. All metals or combinations of metals suitable for soldering Al are electro-negative to Al and as a result soldered joints are prone to attack when exposed to moisture. They should be protected, therefore, by paint or varnish. It is advisable to solder without using any flux. The higher the temp. at which the tinning is done, the better is the adhesion of the tinned layer. E. E. RICHARDSON.

**Monel metal.** JOHN ARNOTT. *Engineering* 106, 451(1918).—Monel metal consists of Ni and Cu, with small amts. of Mn, Fe and Si, all present in solid soln. For microscopic study, polished sections may be etched with alc. +  $\text{FeCl}_3$  or with  $(\text{NH}_4)_2\text{SO}_4$  soln. The physical properties are described. E. E. RICHARDSON.

**The properties of metals as affected by their occluded gases.** COSMO JOHNS. *Trans. Faraday Soc.* (advance copy), 4 pp.(1918).—A review and bibliography of this subject is given. W. T. H.

**Theories of occlusion and the adsorption of iodine by carbon.** JAMES WILLIAM MCBAIN. *Trans. Faraday Soc.* (advance copy), 10 pp.(1918).—True adsorption is nearly instantaneous. Absorption, or solid soln., may be expected to follow Frick's law, which requires a high velocity at first but a rapid falling off in rate with time until equilibrium is produced. In many cases adsorption and absorption both take place. Attention is called to Langmuir's hypothetical explanation and well crystallized views. Expt. on the sorption of iodine by C, extending over exposure periods of 5 min. to 11 yrs. show a rapid surface condensation at first, followed by a very slow and long-continued diffusion which eventually involves more than half of the iodine sorbed. A bibliography is appended. W. T. H.

**The occlusion of gases in metals.** HENRY A. KENT. *Trans. Faraday Soc.* (advance copy), 2 pp.(1918).—General statements. W. T. H.

**General remarks on occlusion of gases in metals.** ALFRED W. PORTER. *Trans. Faraday Soc.* (advance copy), 6 pp.(1918). W. T. H.

**Gases occluded in steel.** THOMAS BAKER. *Trans. Faraday Soc.* (advance copy), 32 pp.—Some years ago B. attempted to discover whether a relation exists between the temp. at which gas is evolved from steel and the critical points of the latter. With hard steels the evolution of hydrogen reached a maximum rate at  $600^\circ$  and the greater part of the gas was evolved at lower temps. CO began to be evolved from the beginning of the expt. but reached its maximum rate at  $688^\circ$ . The quantities of  $\text{CO}_2$ ,  $\text{CH}_4$  and N obtained were very small compared with H and CO, which were evolved in approximately equal amts. Also in *Engineering* 106, 572(1918). W. T. H.

**Grain growth in metals.** ZAY JEFFRIES. *J. Inst. Metals* (advance copy), 32 pp.; *Engineering* 106, 356-60(1918).—This paper represents the first part of a thesis submitted for the degree of Doctor of Sciences at Harvard Univ. The subjects discussed

are: grain growth in the solid state; normal grain growth in metals; exaggerated or abnormal grain growth; general laws of grain growth; typical examples of grain growth; grain growth in cast metals; macro-mechanism of grain growth; micro-mechanism of grain growth; effect of thickness on grain growth; small grains included within large grains. The original paper must be consulted for details. W. T. H.

**Steel castings for ordnance purposes.** Ordnance steel for the army and navy. JOHN HOWE HALL. *Iron Age* 102, 1084-6(1918).—The tests which have to be met with steels furnished the army and navy are given and the specifications are compared with those adopted by the Am. Soc. for Testing Materials and with those of Lloyd's Register. To meet some of these specifications special care must be taken to have the steel thoroughly deoxidized and quiet in the ladle so that it will set sound in the castings and test bars. As much, or more, care should be taken in molding and pouring the test bars as is taken with the castings. Very careful heat treatment must be given the castings. W. T. H.

**Meeting specifications for ordnance purposes.** E. R. SWANSON. *Iron Age* 102, 1086-7(1918).—The specifications for the 3 principal grades of steel furnished the army are now the same as those of the Am. Soc. of Testing Materials as regards the physical properties and the chem. requirements are the same except as regards S. The importance of chem. control and of proper heat treatment is emphasized. W. T. H.

**The heterogeneity of steel.** H. LECHATELIER AND B. BOGITCH. *Compt. rend.* 167, 472-7(1918).—Etching a polished specimen of commercial steel with Stead's reagent, with dil.  $H_2SO_4$  or with I, produces macroscopic evidence of heterogeneity at the surface of the material. This macroscopic etching effect is entirely different from the etching effect which under the microscope reveals the structure of the steel but the quality of the steel can be judged to a certain degree by the macroscopic etching. Just what causes this grosser effect has not been known. Stead assumed that it was in some way related to the P content but this has been disproved by the fact that similar macroscopic etching has been obtained with steel extremely low in P. The expts. now described, which took place with electrolytic Fe quickly, melted with and without addition of oxide, seem to show that the effect is caused by O held in solid soln. by Fe. The effect is lost if the specimen is heated in H. Steel taken from the Martin furnace before treatment with Mn does not show a macroscopic etching effect but steel which has been partially deoxidized does show it. Moreover, the presence of O in solid soln. may explain the fact, noted by Mahler, that the elec. resistance of steel can be computed from the resistivities of each foreign element present if the test is made after the steel has been fully deoxidized but not if made before the final addition of Mn. W. T. H.

**Electrical resistance of hardened steel.** E. D. CAMPBELL. *Engineering* 106, 509(1918).—Steel bars were heated and quenched, and the specific resistances were detd. They were then kept between 100 and 108° and the sp. resistances were detd. at intervals during 12 hrs. A similar set of bars after quenching was kept under oil at room temp. and the sp. resistances were detd. at intervals during 2 years. The change in elec. resistance after 2 years at ordinary temps. was found to be only 35-40% of what it was after 12 hrs. at 100°. S. G. SIMPSON.

**Substitution of niter cake for sulfuric acid in pickling steel.** EDWIN E. CORBETT. *Bur. of Mines*, Oct., 1918, 17 pp.—The substitution of niter cake for  $H_2SO_4$  in pickling steel is advocated in order to conserve materials. Methods of using the cake are discussed and practical questions such as those of shipping and storage as well as expense are considered. From 10 to 20% saving in expense is claimed. An attempt is made to explain the theory of pickling particularly in regard to the effect of  $FeSO_4$ ,  $Na_2SO_4$ ,  $Fe_2(SO_4)_3$ , and various inhibitory agents. W. T. H.

**Inspection of steel arc welds.** O. S. ESCHOLZ. *Iron Age* 102, 1390-1 (1918).—The factors detg. the character of welded joints and methods of testing welds are discussed, with special emphasis placed upon penetration tests and electrical tests. W. T. H.

**Factors in the manufacture of high-grade malleable castings.** J. G. GARRARD. *Iron Age* 102, 1455 (1918).—The art of making heavy castings is discussed. W. T. H.

**The manufacture of semi-steel shells.** ANON. *Iron Age* 102, 1317-21 (1918).—An account of the operations for making semi-steel shell as prepared by the Ordnance Dept. to guide manufacturers. The chem. requirements are stated. W. T. H.

**Black finishes on iron and steel.** ELMER S. WHITTIER. *Metal Ind.* 16, 509-10 (1918).—Processes which are suitable for commercial operations on a large scale are discussed. W. T. H.

**Helical and elliptical springs.** CHAUNCEY T. EDGERTON. *Chem. Met. Eng.* 19, 762-7 (1918).—The manuf. of elliptical and coil springs, the types of steel alloys used, the formulas for calculating the loads, deflections and torsion, the effects of overstrain, and molecular hysteresis are discussed. W. T. H.

**Aluminium and its light alloys.** VI. Bibliography. PAUL D. MERICA. *Chem. Met. Eng.* 19, 729-32, 780-5 (1918); cf. *C. A.* 12, 2532. W. T. H.

**A case of disintegration of a copper-aluminium alloy.** RICHARD SELIGMAN AND PERCY WILLIAMS. *J. Inst. Metals* (advance copy), 2 pp. (1918).—Some wires which had been used for several years to support thin slabs of gelatin showed unusual disintegration. Examination of the corroded material showed that the trouble was due partly to the fact that the wires had been severely overdrawn but chiefly to the presence of 2.65% Cu. W. T. H.

**The alloys of copper and zinc: an investigation of some of their mechanical properties.** F. JOHNSON. *J. Inst. Metals* (advance copy), 6 pp. (1918).—The theory of Kurnakow and Zemczuzny, which forms the basis of work by Turner and Murray, calls for a maximum hardness of the alpha solid soln. at a point midway between the phase boundaries of the equilibrium diagram. In the present work this theory was disproved: a range of uniform hardness was obtained with alloys containing 90 to 70% Cu, but there was no evidence of a pronounced maximum. The hardness curve at the Zn end of the diagram changes its direction twice, (1) at about 5% and (2) at about 15% Cu; but no sudden fall followed by a sharp rise was noted, as indicated by Turner and Murray for sand castings. Alloys consisting entirely of beta solid soln. are stronger than alloys containing either the alpha or gamma soln. in excess. In fact the wholly beta solid soln. (53% Cu) has better mechanical properties than have been attributed to it by former investigators. The Brinell hardness of this alloy was 18.0 as cast and 14.3 when annealed. Its yield point was 10.5 tons per sq. in., its ultimate strength 30.4 tons per sq. in. and the elongation 37.5%. The duplex ( $\alpha + \beta$ ) brasses and the  $\beta$  brass were found to be much more ductile than other investigators have indicated. Two alloys near the Zn end of the series have mechanical properties which do not appear to be appreciated. The alloy with 3.45% Cu has a yield point of 7 tons per sq. in., an ultimate breaking stress of 9.6 tons and elongation of 5%. The other alloy contains 8.8% Cu., shows the same elongation but is about 60% stronger. W. T. H.

**Pure carbon-free manganese and manganese-copper.** ARTHUR F. BRAID. *Bull. Am. Inst. Mining Eng.* 1918, 1697-8, 1783; *Metal Ind.* 16, 357-8 (1918).—Mn in the form of an alloy containing 30% Mn and 70% Cu has been used successfully as a de-oxidizer in casting Ni alloys for drawing purposes. The alloy also removes S. W. T. H.

**Alloys of silicon and their high electrical conductivity.** JAMES SCOTT. *Metal. Ind.* 16, 464-5(1918).—Si-bronze, owing to its high elec. conductivity, is used extensively for telephone and telegraph wires. But little Si is present in the finished alloy as this element acts chiefly as a deoxidizer. The microscopic appearance of pure Si and of the 15% alloy with Cu are described. W. T. H.

**The influence of hot work on the mechanical properties of steel.** G. CHARPY. *Rev. métal.* 15, 427-48(1918); cf. C. A. 12, 2527.—The expts. referred to in the previous abstract are here described in full. W. T. H.

**Researches on alloys rich in zinc.** LEON GUILLET AND VICTOR BERNARD. *Rev. métal.* 15, 407-25(1918).—Alloys containing 88 to 99% Zn, 0 to 5% Al and 0 to 8% Cu were studied as regards hardness, resistance to shock and best temp. of forging, to see if any of these alloys could replace commercial Cu alloys. An alloy contg. 90% Zn and 2% Al, also one contg. 88% Zn, 4% Cu and 8% Al appear to be promising. All the results on some 20 alloys are tabulated. W. T. H.

**A study of cementite transformation and of the equilibrium diagram of the system iron-carbon by means of electric resistance measurements.** IITIRO IITAKA. *Sci. Rep. Tôhoku Imp. Univ.* 7, 167-75(1918).—A marked change in elec. resistance of Fe and steel has been found to take place at the temp. of the  $A_1$ ,  $A_2$  and  $A_3$  transformations and it has been shown that the Fe-C equilibrium diagram can be studied by means of elec. resistance measurements with practically the same results as have been obtained by the study of heating and cooling curves. The  $A_0$  critical point have been detected by means of magnetic observations. The purpose of the present work was to detect this  $A_0$  point by means of resistance measurements and to measure in the same way the so-called S-E line in the Fe-C diagram along which  $Fe_3C$  separates from solid soln. on cooling. By means of an improved differential method, the  $A_0$  point was detected in 6 steels of widely varying C content at 195-212° on heating and at 192°-200° on cooling. These values are a little lower than the temp. detd. magnetically (215°) but agree closely with those obtained by thermic methods. The S-E line was detd. with 10 steels containing 0 to 1.30% C. The values agree well with those already detd. by thermic methods and here also the points detd. with rising temp. were a little higher than with falling temp. It is interesting to note that the  $A_2$  points were detected in the hypereutectoid steels. W. T. H.

**Substituting manganese for phosphorus.** A. F. BRAID. *Foundry* 47, 17(1919).—The use of Mn as a deoxidizer in the production of non-ferrous alloys is discussed. W. T. H.

**Malleable iron in engineering construction.** H. A. SCHWARTZ. *Foundry* 147, 19-24(1919).—The physical properties are discussed in the hope of overcoming objections that are often made by engineers who are not favorable to the use of malleable Fe. W. T. H.

**Metallic electrode arc welding.** O. S. ESCHOLZ. *Eng. Mining J.* 106, 1081-3(1918).—The advantage of electric arc welding over other methods are outlined and methods described for detg. the physical characteristics of welds. W. T. H.

**Steel wool.** GEORGE P. BUTLER. *Metal Ind.* 16, 549(1918).—The use of steel wool for cleaning metals and glass is favored. W. T. H.

**The welding of iron and steel.** W. H. CATHCART. *Iron Age* 102, 1578-82(1918).—The principles underlying the work at the smithy and forge, the effect of oxidation, the use of a flux, the reason that annealing is essential and the desired conditions to be fulfilled are discussed. Photographs are reproduced to show the way in which the scientist can coöperate with the craftsman. W. T. H.

**Nomenclature for electric welding.** H. G. KNOX. *Engineering* 106, 522-6 (1918), illus. E. J. C.

**The relative corrosion of cast-iron, wrought-iron, and steel pipe in house drainage systems.** WM. PAUL GERHARD. *J. Am. Soc. Mech. Eng.* 40, 945-7(1918).—Results of investigation of drainage and vent systems of 78 buildings showed wrought-iron pipe to be more durable for house drains than steel pipe, and steel pipe to be inferior to both cast-iron and wrought-iron pipe when exposed to corrosion. Two forms of corrosion were observed—pitting, and flaking or scaling. The former was characteristic of wrought-iron and cast-iron pipes; the latter was typical of steel pipes. Steel vents in service more than 20 years showed in nearly all cases a very bad deterioration. Also in *J. Franklin Inst.* 187, 99-109(1919). S. G. SIMPSON.

**Hardness testing.** A. F. SHORE AND ROBERT HADFIELD. *Iron and Steel Inst.*, Sept. 12, 1918; *Engineering* 106, 444-70(1918).—From the Hadfield Research Lab. in Sheffield the following questions were sent to S. of New York: (1) Is it possible to find the relation between ball hardness, commencing with 150 up to 800, and scleroscope degrees? Also, for each advance of, say, 50 Brinell nos. what is the difference in scleroscope nos., and what is the necessary factor to convert each of these from Brinell into scleroscope nos., and *vice versa*. (2) Can a special scleroscope be supplied for detg. in Brinell nos. instead of scleroscope, or both, highly hardened products ranging from 550 to 750 Brinell ball? S. has undertaken an elaborate series of expts. to answer these questions and the results are shown graphically in charts. Commenting on these results, H. draws the following conclusions: Chart I shows the statements S. makes with regard to correlating scleroscope and Brinell tests, the latter carried out with 3000 kg. pressure. He shows that there is no very definite relation on these lines, which is in line with common experience. (3) The trouble lies in the way the Brinell test is usually carried out, *i. e.*, with a standard pressure of 3,000 kg. The Brinell test should be carried out so as to give the same size impression on every material. (4) The reason this gives better values is that each piece is then deformed equally. (5) S. argues that his scleroscope test does not much exceed the elastic limit of the material and, therefore, is a guide to elastic limit, whereas the ordinary Brinell test is more of a guide to the tenacity. (6) By reducing the pressure in the Brinell test, better correlation is obtained. This comment is shown to be justified by Chart III. (7) As comment to the above, Chart I, imperfect as it is, is really the best way for comparing scleroscope and Brinell. (8) Chart II shows how scleroscope and Brinell compare when the latter test is made on ideal lines. (9) The use of a diamond ball apparently overcomes the difficulty arising from the deformation of steel balls. It is the best device yet put forward in competition for the Hadfield prize. (10) The difficulty in applying a modification to the Brinell test arises from the fact that different values will be obtained from those now in use the world over. W. T. H.

**The value of the indentation method in the determination of hardness.** R. G. C. BATSON. *Inst. Mech. Eng.*, Oct. 18, 1918; *Engineering* 106, 475-7(1918).—The indentation method for detg. hardness is applied by producing the indentation by a static load or by a blow. A series of tests by both methods was made on mild steel, boiler plate, rail steel, high-C steel and cast Fe. By means of the former method it is shown that a hardness no. can be obtained by using Moore's formula, based on Meyer's conclusion that the mean pressure per unit area is constant for a given angle of impression whatever the diam. of the ball. The hardness no. can be obtained, independently of the load, by calculating it from the slope of the "load-depth of indentation" diagram when this diagram becomes straight. By means of the dynamic method results were obtained showing: (a) The energy of the blow is proportional to the vol. of indentation for both cone and ball indenting tools and the dynamic hardness no. (as applied

by Martel to the cone) is equal to the energy of the blow in kg. divided by the vol. of indentation in cu. cm. (b) The energy of the blow is proportional to the square of the spherical area of indentation for ball indenting tools only (Roos). (c) The vol. of indentation (and therefore the dynamic hardness no.) is approx. independent of the form of indenting tool, whether a cone, a 10-cm. ball or a 4.76-mm. ball. W. T. H.

**The Ludwik hardness test.** W. CAWTHORNE UNWIN. *Inst. Mech. Eng.*, Oct. 18, 1918; *Engineering* 106, 478(1918).—The paper is intended to trace a relationship between indentation hardness tests of ductile metals. The variation of the hardness no. in the Brinell test with the load and size of ball arises from the fact that the indentations are geometrically dissimilar. P. Ludwik has sought to overcome this defect by using a right-angled cone for the indenting tool. The Ludwik apparatus manufactured in Sweden and in Switzerland is used specially for the softer metals but the results vary widely from those obtained by the Brinell method. The Brinell no. is found by dividing the load by the spherical area of the indentation. Just why the spherical area was taken as divisor is not quite clear unless to compensate some increase of hardness no. when the indentation was deep, due to hammer hardening of the material. A better way would be to limit the depth of indentation and define the Brinell no. as  $H = P_b/\pi a_b^2$ , where  $P_b$  is the load in kg., and  $a_b$  the radius of the indentation in mm. Making a similar correction of the Ludwik test the hardness no. is  $L = P_c/\pi a_c^2$ . These 2 values are shown to be concordant. It is suggested that in standardizing the tests the loads should be varied until the vol. of indentation is practically constant.

W. T. H.

**Hardness testing.** GERALD STONEY, *et al.* *Engineering* 106, 469-72.—A discussion of the 2 foregoing papers and that of Edwards and Willis (*J. Inst. Mech. Eng.*, May, 1918; cf. C. A., 12, 2521).

W. T. H.

**The wear of metals.** ANON. *Engineering* 106, 625-9(1918).—A synopsis of ideas on this subject starting with views of C. B. Dudley published in 1890. Finally, results obtained by Guest, Keen and Nettlefolds on a 95-lb. bull-head rail which had been given the Sandberg treatment are described. The results show that the Sandberg sorbitic process greatly increases the tensile breaking strength of the steel and the elongation under stress is decreased to a marked degree. The Brinell hardness is much higher in the treated rail at the top of the head, which is the part most subject to wear. The Messrs. Sandberg presented the process, free of royalty, to the British govt. for use on munitions of war and, after exhaustive tests, it was adopted for reclaiming high-explosive steel which had failed to fulfil the specifications. Photomicrographs are shown which illustrate the effect of the Sandberg treatment.

W. T. H.

**Hardness of soft iron and copper compared.** F. C. KELLEY. *Trans. Am. Electrochem. Soc.* 34 (Preprint)(1918).—Samples of American "ingot iron" and commercial cold-rolled Cu were similarly treated in an elec. heated vacuum furnace and the hardness was carefully detd. by the standard Brinell method. Annealing temps. were 770-950°. Treatment lasted several hrs., followed by annealing in H or *in vacuo*. The range of hardness between dead-soft Cu and commercial Cu is 40 and 80, and the range between H-annealed ingot Fe and the commercial material ranges between 60 and 95. Dead soft Fe may be whittled with a knife and in some cases replace pure soft Cu.

W. H. BOYNTON.

**The constitution of the tin bronzes.** SAMUEL L. HOYT. *Univ. Minn. Bull. Am. Inst. Mining Eng.* 1918, 1721-7.—Alloys of Cu with considerable Sn and less Zn showed marked thermal effects at 520° and 600°. A bar of alloy containing 75% Cu, 15% Sn and 10% Zn was heated to 700° and then by partial removal from the furnace, one end of the bar was cooled to about 400° and after being kept in this condition for

8 hrs. the bar was suddenly quenched. One side of the bar was then ground, polished and etched. At the high temperature, the sand modifications were present. At a somewhat lower temp. a third constituent was formed and at a still lower temp. a fourth phase was proved to exist. The exact significance of these 2 new phases and the critical temps. of  $520^{\circ}$  and  $600^{\circ}$  is not yet clear. W. T. H.

**Bronze bearing metals.** G. H. CLAMER. *Bull. Am. Inst. Mining Eng.* 1918, 1729-33.—The useful bearing alloy containing Cu, Sn, and Pb, with or without a little P, is described and the desirable properties of good bearing metal discussed.

W. T. H.

**The aluminium bronze industry.** W. M. CORSE. *Bull. Am. Inst. Mining Eng.* 1918, 1738-42.—The equil. diagrams of Cu-Sn alloys and of Cu-Al alloys are given and the physical properties of Al-bronze are compared with those of Sn-bronze.

W. T. H.

**Bronzes, bearing metals and solders.** C. K. BURGESS AND R. W. WOODWARD. *Bull. Am. Inst. Mining Eng.* 1918, 1142-50.—The chem. compn. and physical properties of bearing metals, bronzes and solder are discussed with particular reference to the conservation of tin.

W. T. H.

**Babbitts and solder.** G. W. THOMPSON. *Bull. Am. Inst. Mining Eng.* 1918, 1751-2.—A general discussion.

**The cadmium resources of the United States.** C. E. SIEBENTHAL. *Bull. Am. Inst. Mining Eng.* 1918, 1752-9.

W. T. H.

**The metallography of tungsten.** ZAY JEFFRIES. *Bull. Am. Inst. Mining Eng.* 1918, 1641-9, 1779-82; cf. *C. A.* 12, 1637.—An interesting discussion of J.'s paper by Paul D. Merica and by J. C. W. Humfrey, to which J. makes careful reply.

W. T. H.

**The relation of sulfur to the overpoling of copper.** S. SKOWRONSKI. *Bull. Am. Inst. Mining Eng.* 1918, 1637-8; cf. *C. A.* 12, 1269.—F. Johnson suggests that the favorable effect of O may have been due to generation of  $H_2O$  or  $CO_2$  as a result of chemical reaction and the tendency of these gases to escape has acted in opposition to the natural tendency of the ingot to shrink.

W. T. H.

**A metallographic investigation of transverse-fissure rails with special reference to high phosphorus streaks.** G. F. COMSTOCK. *Bull. Am. Inst. Mining Eng.* 1918, 1699-1744.—Careful examination of polished sections etched with  $CuCl_2$  from a great many rails in which transverse fissures have developed show that segregated S does not seem to be the main cause of trouble but rather the segregation of P as shown by the presence of high-P streaks at points where the flaws started. By reheating the blooms from which rails are to be rolled, the P-bands are eliminated more or less completely and the tendency to form transverse fissures is diminished.

W. T. H.

**Experiments in annealing malleable iron.** H. E. DILLER. *Foundry* 46, 564-6 (1918).—The theory of making malleable castings from brittle cast Fe is discussed and expts. are described which aim to det. the best conditions for carrying out the process on a commercial scale. The use of a tunnel furnace is advocated by the aid of which castings can be obtained ready for shipment in 72 hrs. from the time the heat is poured. For the conversion of combined C into temper C, the use of packings or of oxidizing atm. seem to have little effect.

W. T. H.

**Continuous tunnel furnace in the malleable-iron industry.** PHILIP D'H. DRESSLER. *Foundry* 46, 560-8 (1918).—The results of the expts. of Diller (preceding abstract) are discussed and the construction of the tunnel furnace is described in detail.

W. T. H.

**Annealing cold-rolled aluminium sheet.** ROBERT J. ANDERSON. *Inst. Metals*, Sept. 11, 1918; *Engineering* 106, 388-90 (1918).—See *C. A.* 12, 1759.

Sulfide ores are sulfated by roasting the ore, mixed with an Fe compd. or other catalyst if sufficient Fe is not originally present, at above 800°, and afterwards exposing the product to the action of the roast gases. The temp. may be diminished, *e. g.*, from 800°

to 500°, while the roast gases and the ore are moved in the same direction. Ores having a low % of S may be mixed with S or pyrites before roasting. Oxide or other ores containing no S may be heated with a gas containing SO<sub>2</sub> and O, with the addition of a catalyst if necessary. In some cases, the sulfatizing may be stopped at such a temp. that sulfates of only certain of the metals present are formed. Ores of Zn, Cu, Ni, Ag, Cd, Co and Mn are mentioned.

**Metallurgical (crucible) furnace.** B. ZOBEL. U. S. 1,285,883, Nov. 26. The furnace is adapted for prepg. brass, bronze or similar alloys.

**Refining lead.** P. WERNER. U. S. 1,285,511, Nov. 19. Molten Pb is refined (preliminary to its use for coating Fe or steel) by treatment with the products of the destructive distn. of rosin, resinous wood or other resinous material while the surface of the molten metals is protected from the air.

**Lead bullion.** G. P. HULST. U. S. 1,285,714, Nov. 26. Decopperized Pb bullion is subjected to the action of oxidizing agents such as skims containing Pb oxides to oxidize impurities and form a slag or skim, the latter is removed and the softened bullion is treated with Zn to effect desilverization, the impurities in the desilverized Pb are oxidized and the "refiner skim" produced in this last-mentioned operation is added to the charge which has been subjected to the softening treatment, together with "molding skim" resulting from molding of the refined Pb. The desilverized Pb is drossed of Cu skim and the final Zn skim is retorted to obtain Zn, "blue powder," bullion and dross.

**Core mixture for founding.** D. J. REILY and A. DE MATTEI. U. S. 1,286,106, Nov. 26. A mixt. of yellow clay 25 and sand 75% is used for making cores for casting metals. This mixt. requires no org. binder.

**Core mixture for use in metal founding.** J. P. ELLIOTT. U. S. 1,285,081, Nov. 19. Cores for use in casting metals are formed by mixing comminuted asphalt with a body material such as core sand and with a temporary binder such as flour paste. The mixt. is then heated sufficiently to melt the asphalt.

**Steel rail.** R. A. LEWIS, W. R. SHIMER and W. J. THOMAS. U. S. 1,285,749, Nov. 26. A steel rail is finished, *e. g.*, by the method of U. S. pat. 1,285,748, so that it has a microstructure of fine granular pearlite almost free from free ferrite, being formed with a compn. including C 0.60-0.90%, Mn 0.50-1.0% and with S, Si and P in the usual amts. as found in open-hearth rail steel. The rail has a tensile strength of over 115,000 lbs. per sq. in., an elastic limit of over 70,000 lbs. per sq. in., an elongation of over 15%, a reduction in area of over 30% and a hardness of the Brinell test of over 225.

**Heat-treating steel rails.** R. A. LEWIS, W. R. SHIMER and W. J. THOMAS. U. S. 1,285,748, Nov. 26. Highly heated rails as they come from the final forming operation are cooled quickly to 540-700°, conveyed to a heating furnace and therein heated to a uniform temp. of 760-815°, then cooled rapidly to 315-540° and subsequently passed through an annealing furnace wherein the rail is uniformly heated to 540-650°. This treatment produces a hard tough structure.

**Apparatus for heat-treating steel rails.** R. A. LEWIS and W. J. THOMAS. U. S. 1,285,750, Nov. 26.

**Device for quenching steel artillery-shells.** T. F. BAILY and F. T. COPE. U. S. 1,285,583, Nov. 26.

**Treating oxidized ores.** F. A. EUSTIS. Can., 185,443, July 9, 1918. Oxidized Fe ores containing one or more of the metals Ni, Co, Al or Mn are heated in the presence of and intimately mixed with an excess of SO<sub>2</sub>, thus rendering a large amount of the metals sol. The material is then leached and the Fe pptd.

**Bearing metals.** W. H. KELLY. Can. 187,991, Dec. 24, 1918. Bearing metals of Pb and Cu are made by first purifying the Pb by subjecting it while in a molten condition to the action of H and O, then mixing the Pb with pure Cu.

**Case-hardening material.** L. C. MUNN. U. S. 1,286,061, Nov. 26. A material for use in case-hardening Fe or steel is produced by impregnating charcoal with a soln. of Ba(OH)<sub>2</sub> or other Ba compd. and then pptg. BaCO<sub>3</sub> in the pores of the charcoal by the action of CO<sub>2</sub>.

**Apparatus and method for annealing wire electrically.** H. ALEXANDER, W. T. VINT and A. IMBERRY. U. S. 1,285,887, Nov. 26.

**Copper-lead alloy.** G. P. KLING. U. S. 1,285,231, Nov. 19. An alloy of Cu 80 with Pb 20 parts containing about 1-2% of P is prepd. for use in piston-rod packings of steam engines.

**Soldering.** H. C. PROCTER. Brit. 119,688, Oct. 8, 1917. A soldering paste for Al consists of 75% powdered resin, 20% vaseline, and 5% ammonia.

## 10. ORGANIC CHEMISTRY.

CHAS. A. ROULLER.

The synthetic organic chemical industry. FRANCIS H. CARR. *J. Soc. Chem. Ind.* 37, 425-82 (1918).—An address. E. J. C.

**Zirconyl basic benzoates and salicylates.** F. P. VENABLE AND F. R. BLAYLOCK. *J. Am. Chem. Soc.* 40, 1746-8 (1918).—In hot solns. BzOH and acid or neutral ZrOCl<sub>2</sub> form a white, gelatinous ppt. which settles easily and can be readily washed and filtered; it is sol. in NH<sub>4</sub>OH, can be dried to fairly const. wt. at 100° but continues to lose wt. if heated beyond that temp. or if kept over CaCl<sub>2</sub>. Analysis of different preps. indicates that under varying conditions as to concn., etc., no single definite compd. is formed, the ppts. containing varying ratios of the BzO radical to partly dehydrated Zr hydroxide; the values found agree approximately with such formulas as ZrO(OH)<sub>2</sub>.2ZrO(OBz)<sub>2</sub>.6H<sub>2</sub>O, ZrO(OH)<sub>2</sub>.6ZrO(OBz)<sub>2</sub>.6H<sub>2</sub>O and ZrO(OH)<sub>2</sub>.3ZrO(OBz)<sub>2</sub>.16H<sub>2</sub>O. In the case of salicylic acid there seems to be a tendency to the formation of only 1 compd., 2ZrO(OH)<sub>2</sub>.3ZrO(C<sub>7</sub>H<sub>4</sub>O<sub>2</sub>)<sub>2</sub>, with varying amts. of H<sub>2</sub>O. The salicylates are more sensitive to heat than the benzoates, turning brown at 100° and black at 160°. C. A. R.

Chemical nomenclature (CRANE) 2.

MARTIN, GEOFFREY: *Industrial and Manufacturing Chemistry. I. Organic.* 4th Ed. Revized and enlarged. London: Crosby, Lockwood & Son. 764 pp. 36s.

**Chlorinating organic compounds by the aid of light.** W. O. SNELLING. U. S. 1,285,823, Nov. 26. In chlorinating CH<sub>4</sub>, C<sub>2</sub>H<sub>6</sub>, C<sub>2</sub>H<sub>2</sub> or similarly acting compds., a mixt. of Cl with the material to be chlorinated is passed back and forth between transparent baffle plates placed in staggered relation to each other in the chlorination chamber, in such manner that the mixt. travels progressively toward the source of light and the light travels progressively in counter-current first through a mixt. rich in Cl and then to the fresh mixt. containing an increasing proportion of material to be chlorinated. See also U. S. pat. 1,271,790; C. A. 12, 1847.

**Gulonic lactone.** F. B. LAFORGE. U. S. 1,285,248, Nov. 19. Gulonic lactone is made by reacting with HCN upon xylose in aqueous soln., adding  $H_2SO_4$  in sufficient amt. to neutralize the  $NH_4OH$  formed in the reaction and to convert the Na compds. present into  $NaHSO_4$ , evapg. *in vacuo*, allowing the gulonic lactone to crystallize on standing, sepg. the crystals and washing them with cold  $H_2O$ . The pat. is dedicated to the public for free use. The HCN is produced *in situ* from NaCN and  $H_2SO_4$ .

**Phthalic anhydride, phthalic acid, benzoic acid and naphthoquinones from naphthalene.** H. D. GIBBS and C. CONOVER. U. S. 1,285,117, Nov. 19. Phthalic anhydride, phthalic acid, benzoic acid and naphthoquinones are produced by passing  $C_{10}H_8$  vapors mixed with air over a catalytic mass containing V oxides, preferably at a temp. of about  $500^\circ$ . The pat. is dedicated to the public for free employment of the process. Cf. C. A. 11, 134.

**The sulfonation of aromatic hydrocarbons or their derivatives.** H. BULL. Can. 187,834, Dec. 10, 1918. The substance to be sulfonated and  $H_2SO_4$  are caused to react on each other in the presence of a solvent in which the said substance and the sulfonated product are sol. but the  $H_2SO_4$  is not appreciably sol. and the product extd. in the solvent is withdrawn.

***p*-Nitrotoluene-*o*-sulfonic acid.** VARITEOLLISUUS OSAKEYHTIÖ. Dan. 23,344, Aug. 5, 1918. *p*-Cymene is sulfonated and to the product is added  $HNO_3$ , at a temp. of  $40-60^\circ$ , or a mixt. of  $HNO_3$  and  $H_2SO_4$  or K or Na sulfate, at a temp. of  $60-70^\circ$ .

**Methyl alcohol from methyl chloride.** B. S. LACY. Holl. 2,581, Sept. 5, 1918.  $CH_3Cl$  is heated with  $H_2O$  in an acid-binding medium. The reaction is effected under pressure at a temp. above  $100^\circ$ . The required high partial pressure of the  $CH_3Cl$  is maintained by continued addition thereof. Cf. C. A. 12, 702.

**Aldehydes; carboxylic acids.** SELDEN Co. and H. D. GIBBS. Brit. 119,517, Oct. 1, 1917. The oxidation of the side chains of aromatic hydrocarbons or their lower oxidation products is effected by passing the vapor of the hydrocarbon mixed with air or gas containing O, over a catalyst consisting of an oxide of a metal of the 5th or 6th periodic group, *e. g.*, Sb, Bi, Cr, W, U, and particularly V or Mo. Toluene vapor and air passed over  $V_2O_5$  at say  $350-450^\circ$ , give *benzaldehyde* and *benzoic acid*. The catalysts may be used singly or mixed, in a state of coarse or fine division, and on a carrier or not.

**Aldehydes; carboxylic acids; phthalic anhydride; quinones.** SELDEN Co. and H. D. GIBBS. Brit. 119,518, Oct. 1, 1917. The oxidation of aromatic hydrocarbons containing a plurality of side chains or a plurality of rings or their lower oxidation products is effected by passing the vapor of the hydrocarbon mixed with air or other gas containing O, at  $250-650^\circ$  over a catalyst consisting of an oxide of a metal of the 5th or 6th periodic group, *e. g.*, Sb, Bi, Cr, W, U, and particularly V or Mo. Xylene (*o*-, *m*-, or *p*-) vapor and air passed over  $V_2O_5$  at say  $350-550^\circ$  give methylbenzaldehydes, phthalaldehydes, benzenedicarboxylic acids, and some toluic and benzoic acid and benzaldehyde; naphthalene vapor treated similarly gives phthalic anhydride and acid, 1,4-naphthoquinone, benzoic acid, etc.; anthracene vapor at  $350-600^\circ$  gives anthraquinone. The catalysts may be used singly or mixed, in a state of coarse or fine division, and on a carrier or not.

**Purifying anthracene.** SOC. D'ECLAIRAGE CHAUFFAGE ET FORCE MOTRICE. Brit. 119,855, July 23, 1918. Crude anthracene is purified by dissolving it in warm phenols (crude phenol, cresols, xylenols, etc.) and crystallizing out. The crystals are washed with cresol and solvent is removed by heat, benzene, alk. soln., etc. The process may be repeated, and followed by a final purification by means of pyridine.

## II. BIOLOGICAL CHEMISTRY.

## A. GENERAL.

FRANK P. UNDERHILL.

Sir W. H. Thompson. *Nature* 102, 170(1918).—Obituary. ALBERT R. MERZ.

Theory of the mechanism of disinfection, hemolysis, and similar processes. S. C. BROOKS. Harvard Univ. *J. Gen. Physiol.* 1, 61-80(1918).—The following conclusions are drawn from the available data: "1. The course of such processes as hemolysis is very largely dependent upon variations in resistance among the different individuals, and secondarily upon the course of the fundamental reaction. 2. The fundamental reaction may be either a simple process, or the expression of a complex series of changes whose rate is at all times governed by that of the slowest of the series. This might perhaps be regarded as another expression of the so-called 'law of the minimum.' 3. Unnatural assumptions would be requisite for the explanation of a resemblance between the course of such processes in general and that of a monomol. reaction. 4. The supposition that such a general resemblance exists is not supported by the available evidence. 5. The independent detn. of either the nature of the fundamental reaction, or the type of the variation curve for the particular case under observation, will further our knowledge of the nature of such processes and lead to a far deeper insight into the nature and reactions of living matter." JOSEPH S. HEPBURN.

## B. METHODS AND APPARATUS.

STANLEY R. BENEDICT.

Indicator method of measuring the consumption of oxygen. W. J. V. OSTERHOUT. Harvard Univ. *J. Gen. Physiol.* 1, 167-9(1918).—"The blood of the horseshoe-crab (*Limulus*) absorbs O and turns blue when shaken in air. In the presence of certain organisms which consume O it is quickly decolorized. By measuring the time required for the change of color the rate of consumption of O may be detd." A glass tube is used with rubber tubing attached to the open end. During the expt. the rubber tubing is clamped shut to exclude air. A control expt. is made using a tube without the organisms. JOSEPH S. HEPBURN.

Method of studying respiration. W. J. V. OSTERHOUT. Harvard Univ. *J. Gen. Physiol.* 1, 17-22(1918).—The organisms are placed in a wide-mouth bottle provided with a 3-hole cork. The exit tube from the bottle passes beneath the level of an indicator soln. in a stoppered test tube. The exit tube from the test-tube is connected with a rubber syringe, which in turn is attached to a tube passing to the bottom of the bottle containing the organisms. The third hole in the cork contains a tube with stopcock for introduction of reagents. By suitable arrangement of tubing and stopcocks, a U-tube containing solid NaOH may be inserted between the bottle and the test-tube and the gases evolved by the organisms can be passed (a) directly into the indicator soln., or (b) through the U-tube, then through the indicator soln. The air is kept in continuous motion by alternate compressions and expansions of the syringe, mechanically produced. The air is caused to circulate through the U-tube until the color of the indicator soln. becomes constant, then is made to circulate directly through the indicator soln., and the period of time is detd. which is required to produce a definite change in the color of the indicator. The air is again caused to circulate through the U-tube until the original color of the indicator is restored. The detn. is then repeated until the normal time of respiration is established. The reagent, whose influence on

respiration is to be studied, is next introduced; and the period of time required to produce the same definite change in the color of the indicator is detd. as before. It is desirable to compare the times required to produce equal amts. of  $\text{CO}_2$  rather than to compare the amts. of  $\text{CO}_2$  produced in equal times. The initial and final colors may always be controlled by standard tubes containing the indicator and buffer solns. The amt. of  $\text{CO}_2$  produced by the organisms in a given time may be ascertained if desired; the relation between the amt. of  $\text{CO}_2$  in the app. and the  $p_{\text{H}}$  of the indicator soln. is previously detd. by expt.; after respiration it is only necessary to det. the  $p_{\text{H}}$  of the indicator soln. by comparison with similar tubes containing the same concn. of indicator and solns. of known  $p_{\text{H}}$ . The method may also be used for the study of photosynthesis by introducing known amts. of  $\text{CO}_2$  into the app. at the beginning of the expt.

JOSEPH S. HEPBURN.

### C. BACTERIOLOGY.

Hemotoxic action of the diphtheria bacillus and its diagnostic value. S. COSTA, J. TROISIER AND J. DAUVERGNE. *Compt. rend. soc. biol.* 81, 89-91 (1918).—The diphtherolysin was as a rule only detected in well developed cultures; the same bacillus, according to the culture, caused rapid hemolysis in 3 hrs. or delayed hemolysis in 48 hrs. Even the most actively hemolyzing cultures were inactivated by filtration and sometimes by simple sedimentation. The diphtherolysin is thermolabile. The cultures lost hemolytic action when heated 30 mins. at  $60^\circ$  and hemolytic action was greatly reduced by heating at  $48-56^\circ$ . The hemolysin remained intact at  $40^\circ$ . Aging of the cultures produced results similar to those obtained by heating at  $60^\circ$ . The anti-hemolytic action of antidiphtheric serum *in vitro* compared with its favorable action on the anemia of patients indicates that the diphtherolysin, which is an endohemolysin *in vitro*, behaves as an exotoxin *in vivo*. All the diphtheria bacilli which were identified by the biochem. formula previously proposed by C., T. and D. showed hemolytic action *in vitro*, regardless of their origin and their virulence toward guinea pigs. The rapidity of hemolysis was variable, but likewise independent of toxicity or origin. The periods required for hemolysis were 3-6 hrs. in 22%, 10-24 hrs. in 37% and 30-48 hrs. in 33% of the expts. All pseudodiphtheria of the pharynx were found to be without action on glucose, levulose and maltose and likewise without hemolytic action; this confirms the accuracy of the biochem. formula proposed. This method may also be used for differentiating the diphtheria bacillus from the diphtherimorphic bacteria of the cutaneous tissue, nasal fossae and conjunctivae. A considerable no. of races of *B. cutis communis*, the biochem. formula of which had been detd., failed to show any hemolytic action after 5-6 days' contact. The hemotoxic action of the diphtheria bacillus is therefore, contrary to the view of Schwoner, a sp. property and is to be considered in connection with its action on sugars for purposes of identification.

H. S. PAINE.

Acid chlorinated solutions for continuous irrigation of wounds; chlorinated bicarbonate and alum solutions. W. MESTREZAT. *Compt. rend. soc. biol.* 81, 91-3 (1918).—The alkalinity of chlorinated solns. such as the Dakin and Daufresne solns. has the disadvantage of reducing by approx.  $\frac{1}{2}$  the germicidal action of the Cl. The detergent action of such solns. is also considerably less than is often claimed and is not as great as that of the 2 following solns. which are recommended by W.: For the prepn. of (a) the chlorinated bicarbonate soln. add to the required vol. of  $\text{H}_2\text{O}$  the necessary amt. of chloride of lime (depending on the Cl content), allow to stand, decant and add 12 g.  $\text{NaHCO}_3$  (previously dissolved in 100 cc.  $\text{H}_2\text{O}$ ) to each l. of decanted liquid. Add (with agitation) a 10:100  $\text{Na}_2\text{CO}_3$  soln. until the filtered soln., mixed with an equal vol. of 20:100 hyposulfite soln., gives a very slight alk. reaction to phenolphthalein, and then filter. A properly prepd. soln. contains 0.45:100 of active Cl,

and less than 0.5 g.  $\text{Na}_2\text{CO}_3$  and 2-3 g.  $\text{NaHCO}_3$  per l. If too much  $\text{Na}_2\text{CO}_3$  is added the soln. is brought back to neutrality by introducing a current of  $\text{CO}_2$ . This soln. is not stable and should be used within 3 days. In order to prep. (b), the chlorinated alum soln., add to the necessary vol. of  $\text{H}_2\text{O}$  the required amt. of chloride of lime to give the proper Cl content, allow to stand 12 hrs., decant, add 17-20 g. powdered alum per l., allow to stand 2 hrs. and filter. This soln. should contain 0.45:100 of active Cl and should show approx. 0.01 *N* acidity with phenolphthalein indicator. This acidity is detd. by means of 0.1 *N* NaOH after addition of 10 cc. 20:100 hyposulfite soln. to 10 cc. of the filtered soln. Too great acidity increases the coagulating action and may prevent proper irrigation, while too low acidity causes decrease in antiseptic action. Soln. (b) is stable; it causes a flow of serum to the wound and this exudate coagulates on the surface of the tissues.

H. S. PAINE.

**Bactericidal properties of the chlorine ion; comparative study of the antiseptic action of acid and alkaline hypochlorite as used in surgery.** R. J. WEISSENBAUGH AND W. MESTREZAT. *Compt. rend. soc. biol.* 81, 93-6(1918).—W. and M. studied the comparative bactericidal action of Dakin-Daufresne alk. hypochlorite soln. and solns. (a) and (b) (cf. preceding abst.) on *B. perfringens*, pyocyanic and paratyphoid bacilli, yellow staphylococcus and spores of *B. sporogenes*. The active Cl content of the solns. varied from 0.42:100 to 0.46:100 in different expts. but, for any given expt., was kept rigorously the same for all 3 solns. The bactericidal action of all 3 solns. on the spores of *B. sporogenes* was nil, even after 24 hrs. contact. The min. time required to kill the bacteria by contact with the alk. hypochlorite soln. was approx. twice that required with solns. (a) and (b), the periods required being practically the same for the 2 latter. The bactericidal action for the same soln. and the same bacillus varied within very narrow limits from 1 expt. to another for the same concn. of soln. The variations in bactericidal action for the same soln. and different bacilli were comparatively slight; the min. periods of contact with the 4 bacilli required for the Dakin-Daufresne and (a) and (b) solns. were 45-60, 20-30 and 20-30 mins., resp. The greater bactericidal action of the acid solns. is connected with the ready decompn. of  $\text{HClO}$  in an acid medium with production of nascent O.

H. S. PAINE.

**Study of the Pfeiffer bacillus.** A. LATAPIE. *Compt. rend. soc. biol.* 81, 833-5 (1918).—A serum with pronounced sp. properties was obtained from animals immunized with the Pfeiffer bacillus. The serum had a distinct curative action and prevented the death of guinea pigs after inoculation with lethal amts. The serum of the immunized animals (goats) was toxic in the case of blood withdrawn too soon after the last injection of bacteria. Intraperitoneal injection of this serum killed guinea pigs and subcutaneous injection caused edema. Serum from blood withdrawn 20 days after the last injection did not show any toxicity.

H. S. PAINE.

**Nonagglutinable bacteria.** M. NICOLLE, C. JOUAN AND E. DERAINS. *Compt. rend. soc. biol.* 81, 839-40(1918).—One-tenth cc. of *N* HCl was added to 20 cc. of an emulsion of 1 cg. of gonococci in physiol. NaCl soln.; the mixt. was heated 5 mins. in boiling  $\text{H}_2\text{O}$ , cooled and neutralized with 0.1 cc. of *N* NaOH. The gonococci, after treatment with HCl, were readily agglutinated by an antigonococcic serum which, before this treatment, failed to cause agglutination, although it readily fixed complement in their presence and exhibited undeniable therapeutic action. A no. of races of pneumococcus which were not agglutinated by various antipneumococcic sera were readily agglutinated by the appropriate sera after treatment with HCl. The conception of a separate and strictly nonagglutinable type of pneumococci should be abandoned. It was necessary in some cases to increase the above proportion of HCl to 0.2-0.5 cc. Treatment of nonagglutinable bacteria with NaOH usually failed to give as good results as treatment with HCl (equally as good results in a few cases,

but rarely superior). Restoration of agglutinability in this manner has considerable practical value for the sero-identification of races of pneumococci and various other nonagglutinable bacteria. This restoration of agglutinability is, as stated by Porges, due to hydrolysis of the mucous capsule.

CARL L. ALSBERG.

Present state of the anthocyanin question., II. Chemical constitution of anthocyanin. J. BEAUVERIE. *Rev. gén. sci.* 29, 604-12(1918); cf. C. A. 13, 139. E. J. C.

Difference in the action of radium on green plants in the presence and absence of light. CHARLES PACKARD. *J. Gen. Physiol.* 1, 37-8(1918).—The Ra prepn. contained 20.4 mg. of Ra element and was enclosed in a thin-walled Ag tube, which was placed in a watch-glass filled with water; *Spirogyra* filaments were laid across it; a typical phenomenon of disintegration occurred; the chlorophyll bands first contracted somewhat and lost their spiral shape, then resolved into an irregular heap of chlorophyll at one end of the cell. The cells nearest the tube containing Ra showed this phenomenon in 2.5 to 3 hrs. in the light, and in 35 to 70 (av. 45) min. in the dark. The tube containing Ra was introduced into a small glass tube in which colonies of *Volvox* were present; the av. time required for the colonies to become motionless was: 2 hrs. in the light, 55 min. in the dark. "It is very evident that the life of the cell is prolonged by some condition connected with photosynthesis."

JOSEPH S. HEPBURN.

Experiments on the injurious effects of frost on grains and legumes. H. FISCHER. *Jahresbericht Vereinigung angew. Botanik* 13, 92-141(1916); *Z. Pflanzenkrankh.* 27, 314(1917); *Biedermanns Zentr.* 47, 212-3(1918).—Plants affected by frost show a blackish green coloration of the leaves which corresponds with a marked plasmolysis of the cell-contents but which is also ascribable to the direct effect of cold on the chlorophyll pigment. Numerous expts. on the effects of cold on grains and legumes are reported and discussed.

ALBERT R. MERZ.

Growing lupines with a low alkaloid content. TH. RÖMER. Bromberg. *Landw. Jahrb.* 50, 433-4(1917); *Biedermanns Zentr.* 47, 209-12(1918).—Lupines contain 0.2 to 1% alkaloid, which it has for the most part been necessary to remove by Kellner's process. Lupines thus treated must be fed immediately or dried, as they can not be kept in a wet state. Expts. have been conducted to ascertain whether lupines could be raised which could be fed directly to cattle without previous removal of their bitterness. Crossing of different varieties was unsuccessful as the hybrids were seedless. Whether improvement can be brought about by selection has not yet been detd. though it has been definitely ascertained that the descendants of individual plants show considerable differences in alkaloid content. It remains to be seen whether these differences are inheritable. Only the Steiner-Baumert method could be used for the detn. of alkaloid though even this is tedious. Using Steiner's factor of 500 for obtaining the degree of bitterness, blue lupines have a bitterness of approx. 30; lupines treated by Kellner's process, approx. 10. The taste becomes distinctly bitter at 12. ALBERT R. MERZ.

Reflections upon the chemical analyses of marine algae. C. SAUVAGEAU. *Rev. gén. sci.* 29, 541-51(1918).—A review of the studies on the chem. compn., especially the K and I contents of marine algae. The criticism is given that analyses have often been made upon material comprizing different species, gathered at different times of the year, from various habitats and of different stages of development. It is emphasized that these factors have an important bearing on the chem. compn. of marine algae.

CHAS. H. RICHARDSON.

Note upon the hydrogen-ion concentration necessary to inhibit the growth of four wood-destroying fungi. MERLE R. MEACHAM. *Science* 48, 499-500(1918).—The following species were studied upon synthetic and malt extract media: *Lensile sepiaria*, *Pomes roseus*, *Comiophora cerebella* and *Merulius lachrymans*. The response to H-ion was about the same in the four species, and the curves (obtained by plotting as ordinates the wts. in g. of mycelium produced in 5 weeks with the  $P_H$  values as abscissas) were similar to those showing the relation between enzyme activity and H-ion concn. The first critical point, i. e., the point where the first marked deflection in the growth curve occurred, was reached when the  $P_H$  was equivalent to about  $1/100$  N acidity and the limiting acidity was reached when the  $P_H$  equaled about  $1/60$  normal.

ANDREW HUNTER.

Present status of our knowledge of fatigue products. ERNEST L. SCOTT. *Public Health Repts., Reprint* No. 465; *Am. J. Public Health* 8, 735(1918).—S. summarizes his paper as follows: (1) Substances carrying H-ions, as lactic and  $\beta$ -hydroxybutyric acids,  $KH_2PO_4$  and  $CO_2$ , stand as causal agents of fatigue. (2) Certain products of protein disintegration, as indole, skatole and phenol, may produce fatigue symptoms, and may be active agents in producing normal fatigue. (3) There is some evidence that the negative ion of lactic and  $\beta$ -hydroxybutyric acids and that certain positive ions, especially  $K^+$ , are capable of producing certain fatigue phenomena. (4) There is no evidence that the negative ions of  $H_2CO_3$ ,  $H_2PO_4$  or  $H_2SO_4$  are fatigue substances. (5) There is no evidence at present for the existence of sp. fatigue substances as proposed by Weichardt. (6) There is very little probability that creatine or creatinine have any relation to fatigue or to muscle work in general. (7) There are no doubt numerous compds., as purine bases, uric acid, etc., which may be increased by work, but which have no causal bearing on fatigue.

E. J. C.

Is there a thymic hormone? E. R. HOSKINS. *Endocrinology* 2, 241-57(1918).—After an exhaustive critical review of the literature, the following conclusion is reached: "Whatever be the real function of the thymus, certain it is that its production of an internal secretion has not been proved. The evidence in favor of such a theory is but circumstantial at best and very meager. It is equally difficult to prove that the thymus does not produce a secretion, but the burden of proof is upon those who support the former theory." It is suggested that the thymus functions during infancy and childhood as a lymphoid organ producing lymphoid cells and leucocytes; its atrophy occurs as the body acquires resistance to infection, and the lymphocyte percent decreases in the blood. A bibliography of 41 references is appended.

J. S. H.

Active coöperation between the physiologist and the clinician and comparative analysis of coördinated data in the study of the internal secretions. CHARLES E. DE M. SAJOUS. *Endocrinology* 2, 258-82(1918).—The 1918 Presidential Address of the Assoc. for the Study of the Internal Secretions. The thesis presented is that the knowledge of the endocrine glands will be greatly increased by coöperation of the clinician and the physiologist, utilizing the special knowledge of each. The internal secretion of the adrenals is discussed at length, with stress on its role in the alveolar gas exchange, tissue oxidation, and the O-carrying power of the blood—the respiration theory.

JOSEPH S. HEPBURN.

Iodine as the active principle of the thyroid gland. W. W. SWINGLE. Princeton Univ. *Endocrinology* 2, 283-8(1918).—Both normal and thyroidectomized larvae of

the common leopard frog (*Rana pipiens*) and of the toad (*Bufo lentiginosus*) were used as exptl. animals. Separate groups of the same age were given one of the four reagents: I, KI, KIO<sub>3</sub>, and CHI<sub>3</sub>; and the influence upon the metamorphosis was detd. I produced metamorphosis in both normal and thyroidectomized larvae more rapidly than any of the other reagents; CHI<sub>3</sub> was slightly less potent than I; KI was much slower than CHI<sub>3</sub>; and KIO<sub>3</sub> had practically no effect. The normal larvae, which had received I, had very much smaller thyroids than control larvae of the same age and size. "The results of the expts. appear to indicate very strongly that I is the active principle of the thyroid gland, and that this substance functions within the organism as a hormone itself without the intermediation of the gland. The function of the thyroid, then, appears to be chiefly that of extracting and storing the physiologically active I, rather than elaborating an active hormone itself." Normal blood serum was found able to dissolve 0.00075 g. I per cc. JOSEPH S. HEPBURN.

Effect of the X-ray upon the response of tadpoles to thyroid stimulation. CAREY P. McCORD AND CARLTON J. MARINUS. *Endocrinology* 2, 289-300(1918).—Selected tadpoles of the bull-frog (*Rana catesbeiana*) were subjected to the action of Röntgen rays in small amts. Certain individuals were then treated with thyroid gland preps. and their rate of metamorphosis compared with the rate in (1) normal tadpoles, (2) thyroid-fed tadpoles not irradiated, and (3) irradiated tadpoles not fed thyroid. The results indicated that irradiation apparently was without effect on normal tadpoles, but produced a slight, nevertheless distinct, increase in the susceptibility of young tadpoles to thyroid stimulation. JOSEPH S. HEPBURN.

Antagonism between thymus and parathyroid glands. EDUARD UHLENHUTH. Rockefeller Inst. *J. Gen. Physiol.* 1, 23-32(1918).—Thymus is substituted for thyroid in the title as a correction. The larvae of salamanders do not possess parathyroids. When larvae of the species *Amblystoma maculatum* and *A. opacum* were fed exclusively on calf thymus, tetany invariably developed; the symptoms closely resembled those of the tetany which follows parathyroidectomy in mammals. The tetany did not develop in the larvae until their thymus glands were able to secrete. "This suggests that tetany is the effect of the combined action of the secretion of certain substances by the thymus glands of the larvae and of substances introduced into the larva by feeding it with the thymus gland from other animals." During metamorphosis the parathyroid glands develop; and tetany does not occur after metamorphosis. The larvae possess a second mechanism to counteract the action of the thymus; *A. maculatum* and *A. opacum* larvae possess 6 well developed thymus glands and no parathyroids, yet are not normal victims of tetany; moreover larvae of *A. tigrinum* do not develop tetany even on a diet of thymus, though they also lack parathyroids. In the larvae of the first 2 species this second mechanism "is sufficient only to prevent tetany from the animal's own thymus, while in the larvae of *A. tigrinum* it is capable of preventing tetany even when the larvae are fed with thymus." In man, tetany occurs more frequently in children than in adults, perhaps because in the latter the thymus has been largely replaced by connective tissue. Tetany in pregnancy may possibly be due to the fact that the parathyroids of the mother may be able to prevent tetany from her own largely atrophied thymus, but are insufficient to prevent tetany from the excess of the thymus substance furnished to the blood of the mother by the fetus. JOSEPH S. HEPBURN.

Further proof of the existence of a specific tetany-producing substance in the thymus gland. EDUARD UHLENHUTH. Rockefeller Inst. *J. Gen. Physiol.* 1, 33-6 (1918).—The tetany produced in salamander larvae by a diet of thymus (see preceding abstract) is not due to a deficiency in the ration. Earthworms constitute a complete diet for the larvae; nevertheless when larvae of *Amblystoma maculatum* were fed alter-

nately, one day on thymus and one day on earthworms, tetany developed and was due to a specific tetany-producing substance contained in the thymus gland. "The effect of the thymus gland in producing tetany is due to a specific tetany toxin produced by and contained in the thymus, and the thymus gland must be added to the group of glands for which the function of internal secretion has been demonstrated."

JOSEPH S. HEPBURN.

**Cholesterol content of the suprarenals at different stages of fetal life.** A. CHAUFARD, GUY LAROCHE AND A. GRIGAUT. *Compt. rend. soc. biol.* 81, 87-9(1918).—The cholesterol content of the liver and kidneys varied only slightly during fetal life and showed approx. physiol. values from practically the beginning of intrauterine life. The cholesterol content of the suprarenals reached a value in 3 mos. which was equal to the max. value for the liver and kidneys; it increased rapidly with the age of the fetus and reached an av. value of 15 g. per 1000 at birth. While the cholesterol content of the liver and kidneys had a value characteristic of normal tissue compn. that of the suprarenals was in the nature of a reserve. During the initial stage of intrauterine life the cholesterol requirements of the fetus are supplied solely by cholesterol hypogenesis on the part of the mother. During the later stages endogenous cholesterol secretion is a parent in the suprarenal cortex of the fetus.

H. S. PAINE.

**Digestion in the region of the cecum.** P. CARNOT AND H. BONDROY. *Compt. rend. soc. biol.* 81, 487-90(1918).—Digestion and absorption in the region of the cecum was studied in a subject with cecal fistula and partial obstruction of the colon, thus permitting comparison of the anal and cecal evacuation. Sucrose (20 g. in 200 cc. H<sub>2</sub>O ingested during fast) appeared in considerable amt. in the cecal evacuation in 1 hr., remained in appreciable amt. after 2 hrs. and was not detected after 2½ hrs.; it did not appear in the anal excretion. Lactose (50 g. in aq. soln. during fast) passed into the cecum in 2 hrs. When the subject ingested at the same time an appreciable amt. of yoghurt the cecal evacuation (ordinarily neutral) was distinctly acid and contained lactic acid due to fermentation of lactose. The anal stools were not acid and contained neither lactose nor lactic acid, these substances being entirely absorbed in the cecum and ascending colon. The cecal evacuations became neutral when ingestion of lactose was discontinued, although yoghurt continued to be ingested. Starch (30 g. as paste during fast) passed in part to the cecum where it was detected after 3 hrs. and for 3 hrs. thereafter; it was accompanied by erythrodextrins which were absorbed at this point. Ovalbumin and albumoses, but not peptones, were detected in the cecal evacuation 3 hrs. after ingestion of 2 egg whites in 250 cc. H<sub>2</sub>O during fast. The albumoses disappeared after 4 hrs. but traces of ovalbumin remained. No ovalbumin, albumoses or peptones appeared in the corresponding anal stools. Crystals of tyrosine also appeared in the cecum. Tyrosine was not found in the ileum by Macfadyan, Nenki and Sieber and it appears that degradation of albumins is completed in the cecum. Indole and phenols were detected in the cecal content. Peptones (10 g. in 250 cc. H<sub>2</sub>O during fast) were not detected in the cecum and were entirely absorbed or transformed in the small intestine. Further expts. relative to fats and soap are required. Invertase was present, but trypsin, lipase, diastase and rennin were not detected in the cecum. The true bile pigments were also not present in the cecum, although urobilin was readily detected. Bile salts (Pettenkoffer reaction) were not detected; they were entirely absorbed or transformed in the small intestine. The absorption of various medicaments was studied. Certain easily absorbed sol. salts did not appear in the cecum (at least when administered in therapeutic doses). Salts such as KI and Na salicylate (1 g. in soln. during fast) which are quickly absorbed and readily eliminated in the urine did not reach the cecum. Purgatives usually reached the cecum. Rhubarb (1 g. during fast) was only detected (Borntraeger

reaction) in the cecal evacuation after 5 hrs. and disappeared within 1 hr. Similar results were obtained with senna. Phenolphthalein (0.3 g. ingested) gave after 2 hrs. a distinct reaction which reached a max. after 5 hrs. and continued for 7 hrs. The role of the cecum is, therefore, not negligible. While enzymic activity in the cecum is slight, absorption at this point is very considerable. The delay in appearance of the purgatives in the cecum appears to correspond to the rate of the purgative action itself. Absorption of  $H_2O$  in the cecum was also observed to be intense.

#### G. PATHOLOGY.

H. GIDEON WELLS AND ANDREW HUNTER.

A glycerol "extract" of tubercle bacilli as an antigen in complement fixation. S. A. PETROFF. Trudeau, N. Y. *Am. Rev. Tuberculosis* 2, 523-4(1918).—The following antigen is recommended as the most reliable of the single antigens tried. Tubercle bacilli are grown on 4% glycerol beef-broth 4 to 6 weeks, the cultures filtered off, washed with sterile  $H_2O$ , dried over  $H_2SO_4$  several days, and pulverized in ball mill for several weeks. One g. of pulverized bacilli is triturated in a mortar with 100 cc. 25% glycerol and boiled slowly for 1 hr. under a reflux condenser, after which the clumps are allowed to settle and the supernatant suspension used—0.1 cc. of a 5% diln. representing  $1/4$  of the anticomplementary point.

H. J. CORPER.

The clinical value of complement fixation in pulmonary tuberculosis based on a study of 540 cases. LAWRASON BROWN AND S. A. PETROFF. Trudeau, N. Y. *Am. Rev. Tuberculosis* 2, 525-40(1918).—A positive complement fixation test was obtained in 72% of 478 patients in whom a diagnosis of tuberculosis was made; 51% of the incipient, 73% of the moderately advanced and 81% of the far advanced were positive; when activity was present 81%, absent 61%, and questionable 79% were positive; 9.8% of patients who have had tubercle bacilli in the sputum at some time reacted negatively; 90% in whom tubercle bacilli were present at time of examn. were positive; a larger percentage (85%) of cases with hemoptysis than of those without (64%) were positive; patients with a negative reaction can be allowed to exercise more freely than those with a positive. The complement fixation test and cellular hypersensitiveness as manifested by the intradermic reaction to old tuberculin do not run a parallel course; many patients react to the tuberculin and have a negative complement fixation test (the opposite may occur). Patients with pleurisy with effusion do not react readily, and the presence of a positive Wassermann test has no bearing upon the complement fixation test in tuberculosis. Only  $1/4$  of the incipient,  $1/4$  of the moderately advanced and  $1/4$  of the far advanced cases show any change in their reaction during five to six months.

H. J. CORPER.

The complement fixation test in tuberculosis. LINDA B. LANGE. Baltimore, Md. *Am. Rev. Tuberculosis* 2, 541-5(1918).—Four antigens (bacillary suspension of Miller and the NaOH,  $CH_3OH$ , and potato broth culture filtrates of Petroff) were used in the examination of 856 sera. Tuberculous sera gave 51.5% of fixation of any degree while non-tuberculous sera gave 13.6%. The alc. antigen gave the highest percentage

of strong fixations in clinically tuberculous cases and the NaOH antigen the lowest. With the sera from non-tuberculous cases the greatest proportion of strong fixations was obtained with the NaOH antigen and the smallest with the potato filtrate antigen. All tend to give a greater percentage of strong fixations with the sera of more advanced active pulmonary cases than with those of the less advanced. The results obtained in non-tuberculous medical cases (of all types) are given. Of 147 patients giving a positive Wassermann reaction but free from clinical tuberculosis 22 gave a positive tuberculosis fixation.

H. J. CORPER.

The value of tuberculosis complement fixation in clinical tuberculosis. B. STRIVELMAN. Bedford Hills, N. Y. *Am. Rev. Tuberculosis* 2, 546-50(1918).—Examn. of 205 cases using Miller's antigen for complement fixation revealed about 52% positive reactions alike in active and inactive consumptives; 41% of active tuberculous cases with positive sputum and 72% of active cases with negative sputum showed a negative tuberculosis fixation reaction. A positive reaction is obtained more frequently as the disease progresses while in early cases the percentage of positive reactions is exceedingly low (15.8% active and 39.5% inactive). Of non-tuberculous cases 32% were positive.

H. J. CORPER.

Attempts to reduce the resistance of the guinea pig to tuberculosis by means of various agents. The effects of the Röntgen ray, benzene, Thorium X, tuberculin, ether and chloroform. H. J. CORPER. Chicago. *Am. Rev. Tuberculosis* 2, 587-603 (1918).—These expts. were performed to find a substitute (available to all) for the X-ray for increasing the susceptibility of the guinea pig to tuberculosis, a method recommended by Morton (*J. Exp. Med.* 24, 419-27(1916)) for hastening the animal diagnosis of tuberculosis. A single exposure to the Röntgen ray (as directed by Morton), sufficient to cause a temporary leucopenia in guinea pigs infected with a small amt. (0.000001 mg.) of virulent human tubercle bacilli, produced no appreciable effect upon the course of the macroscopic tuberculosis in these animals. Likewise a leucopenia (as low as about 2500, as compared to a normal of about 12,000 leucocytes per cu. mm. of peripheral blood) occasioned by the X-ray, existing at the time and persisting throughout the period of infection, produced just as little effect.  $C_6H_6$ , in a single large (7.5 cc.) or repeated small (1 cc.) subcutaneous injections with an equal part of paraffin (m. 56°), or inhaled once or twice daily for a month to the point of anesthesia, had no appreciable effect upon the course of the macroscopic tuberculosis in guinea pigs produced by the injection of virulent human tubercle bacilli. Benzene injected subcutaneously into guinea pigs with an equal part of paraffin is slowly absorbed,  $\frac{1}{2}$  remaining the first day,  $\frac{1}{2}$  after the second,  $\frac{1}{2}$  after the third and  $\frac{1}{10}$  after the tenth day. Th X in amt. sufficient to maintain a marked leucopenia (as low as approx. 1500 leucocytes per cu. mm. of peripheral blood) throughout the entire period of infection of guinea pigs by the subcutaneous injection of virulent human tubercle bacilli (0.000001 mg.) produced no effect upon the course of the macroscopic tuberculosis in these animals. Tuberculin (Koch's O. T.) in large doses also had no appreciable effect upon the course of human tuberculosis in the guinea pig.  $Rt_2O$  by inhalation to the point of light anesthesia daily for about a month did not increase the susceptibility of guinea pigs to tuberculosis.  $CHCl_3$  inhalation proved highly toxic and were only given a short time without effect upon the tuberculosis of the guinea pig.

H. J. CORPER.

Laboratory investigations on the physical properties of root filling materials and the efficiency of root fillings for blocking infection from sterile tooth structures. WESTON A. PRICE. *J. Nat. Dental Assoc.* 5, 1260-80(1918).—The physical properties of gutta-percha and its solns. are described at length. Bacteriological expts. on teeth demonstrated that gutta-percha fillings by no means prevented subsequent bacterial infection of the teeth. The paper contains reports by Dayton C. Miller on: Expansion of

sheet gutta-percha; effects of  $\text{CHCl}_3$  on gutta-percha; some physical properties of rosin dissolved in  $\text{CHCl}_3$ , gutta-percha dissolved in  $\text{CHCl}_3$ , and gutta-percha dissolved in  $\text{CHCl}_3$  and eucalyptol oil.

JOSEPH S. HEPBURN.

Opsonin investigation in wounded soldiers with wounds infected with streptococcus. LÉ FÈVRE DE ARRIC. *Compt. rend. soc. biol.* 81, 827-9 (1918).—The serum of wounded soldiers with recent wounds infected with streptococcus gave low opsonic values, almost always less than unity. The heated serum of the same soldiers always gave high opsonic indexes, greater than unity. Opsonic detns. on the serum of wounded soldiers with old streptococcic wounds (6-12 weeks following the lesion) gave values sometimes higher but oftener less than 1. High results were always obtained with inactivated sera. The highest opsonic indexes were found, as a rule, in the case of the oldest wounds. Expts. by heating (to  $56^\circ$  or higher temps.) showed that, with rare exceptions, the sera of soldiers with streptococcic wounds was always richer in thermostable opsonizing substances than was normal serum. In general the opsonic index for the same individual increased with the evolution of the wound. The highest values, and especially those obtained with heated sera, were found in the case of very old wounds. A no. of observations indicated that as the opsonic index of the serum increases the bacteria may become independently more susceptible to phagocytic attack. This fact is perhaps connected in some way with attenuation, although there is nothing to show that attenuation or reduction of germinative power is not the exact result of the prolonged action of the medium, serum or exudate. In this connection it should be noted that, according to Levaditi, streptococcus very often sensitizes the organism for a considerable period instead of immunizing it. The above results are believed to warrant the view that the opsonic effect is one of the manifestations of immunity. H. S. P.

## H. PHARMACOLOGY.

ALFRED N. RICHARDS.

Comparative studies on respiration. I. Introduction. W. J. V. OSTERHOUT. *J. Gen. Physiol.* 1, 171-9 (1918).—The technic of the indicator method for the study of respiration (see C. A. 10, 2470; 13, 231) and its applications are discussed. By this method, the following results were obtained: "When anesthetics are employed in sufficient concn. to produce any result, plants show a rise in the rate of respiration which is followed by a fall. In the animals studied, the rise (found in higher concns. only) was preceded by a temporary fall which is not entirely due to lowering of muscular activity or tonus. In lower concns. the effect on animals was merely a decrease of respiration." II. Effect of anesthetics and other substances on the respiration of *Aspergillus niger*. F. G. GUSTAFSON. *Ibid* 181-91.—When the concn. was high enough to produce any effect,  $\text{HCHO}$ , ether, and acetone produced an increase, followed by a decrease in the rate of respiration. When a 3.65% soln. of ether in water was used, it caused an increase in the rate of respiration with certain cultures, but caused only a decrease with other cultures of the mold. When 7.3% ether (satd. aq. soln.) was used, the reaction which caused an increase in the respiration was a reversible process, while the reaction which caused the decrease was not reversible. Caffeine in 0.5% soln. only decreased the respiration, while its satd. soln. first increased, then decreased the respiration. III. Effect of ether on the respiration and growth of *Bacillus subtilis*. MARTHA M. BROOKS. *Ibid* 193-201.—Aq. solns., containing from 0.037% to 7.3% ether, produced an increase, followed by a decrease, in the rate of respiration of *Bacillus subtilis*. A 7.3% soln. of ether in tap water increased the output of  $\text{CO}_2$  to 50 times its normal value; this increase did not occur when a 7.3% soln. of ether in 0.85%  $\text{NaCl}$  soln. was used; apparently antagonism exists between  $\text{NaCl}$  and ether.

Low concns. (0.037 to 1.1%) and high concns. (3.65 to 7.3%) of ether were toxic to *B. subtilis*, while intermediate concns. (1.1 to 3.65%) stimulated its growth. IV. Effect of ether on the respiration of wheat. HELEN S. THOMAS. *Ibid* 203-7.—When wheat seeds, which had been soaked for 12 hrs. and had entered on the first stages of germination, were treated with aq. solns. containing 7.3% and 3.65% resp. of ether by vol., their rate of respiration first increased, then decreased. V. Effect of ether on the production of carbon dioxide by animals. MARIAN IRWIN. *Ibid* 209-20.—With *frog tadpoles* 0.15, 0.37 and 0.55% ether solns. decreased the output of CO<sub>2</sub> while the movements of the body and of breathing remained normal; the effect was reversible. Ether in concns. of 3.65% and 7.3% produced a decrease in respiration, followed by an increase to as high as 3 times the normal rate, after which a decrease again occurred; the effect was irreversible. With the common *whirligig beetle* (*Dineutes assimilis*), 7.3% ether produced the sequence: decrease, increase, decrease in respiration, the effect being irreversible; 7.3% ether gave similar results with *frog eggs* in the blastopore stage. With *fish embryos* (*Fundulus heteroclitus*), a reversible decrease in production of CO<sub>2</sub> occurred in 0.73% ether; this decrease was not sufficient to produce narcosis. In 3.65% ether, a temporary decrease was followed by an increase, then came another decrease; in 7.3% ether an immediate increase of as high as 307% occurred, after which a decrease was noted; these increases were accompanied by irreversible changes ending in death. "These expts. show that narcosis is not due to asphyxia. The action of anesthetics is due to some other cause than the effect on respiration." In animals the increase in CO<sub>2</sub> output was accompanied by irreversible changes leading to death; this was not necessarily the case in plants. The reversible (narcotic) action of ether was accompanied by a decrease in CO<sub>2</sub> production in animals, but not in plants as a rule.

JOSEPH S. HEPBURN.

Slight toxicity of colloidal arsenic. E. SOREY. *Compt. rend. soc. biol.* 81, 57-8 (1918).—Intravenous injection of colloidal As in amts. less than 0.05 g. per kg. never caused death in case of rabbits; the latter developed normally in spite of daily injections of 0.04 g. As per kg. for 15 days. Death did not always occur after doses of 0.05 g. per kg.; injection of at least 0.08 g. per kg. was required in order to cause certain death within 24 hrs. The primary mechanism of death was the same as with all undissolved substances (whether colloidal or not) introduced into the blood stream, *i. e.*, obstruction of the pulmonary capillaries. Animals killed in this manner showed the usual symptoms of asphyxia and congestion of the lungs. The lungs of animals killed by colloidal injections assumed the color of the colloid (grayish in the case of As). Colloidal As did not, however, act entirely in a mechanical manner; As was found in soln. in the urine and must, therefore, have reacted in a chem. manner in some portion of the organism. This solvent action was very slow and the As was well tolerated even in the max. sublethal amts. It should be possible intravenously to inject 3 g. colloidal As into a 60 kg. man without danger, this amt. being equiv. to 15 g. arsenobenzene, 6.30 g. Na cacodylate, 10.80 g. arrhenal, 9.60 g. atoxyl, 7.70 g. As<sub>2</sub>O<sub>3</sub>, 12.30 g. Na arseniate.

## I. ZOÖLOGY.

R. A. GORTNER.

Studies on bioluminescence. VII. Reversibility of the photogenic reaction in *Cypridina*. E. NEWTON HARVEY. *J. Gen. Physiology* 1, 133-45 (1918).—At least three substances are concerned in light production in the crustacean, *Cypridina*, namely luciferin, luciferase and photophelein. Luciferin, previously included in the definition of photophelein, is a compd. oxidizing with light production, dialyzable and relatively resistant to heat. It is found only in luminous animals. Luciferase, previously called photogenin and similar to luciferase as described by Dubois (*Compt. rend. soc.*

*biol.* 37, 559 (1885)), is destroyed by boiling, is non-dialyzable and accelerates the oxidation of luciferin. Luciferase has many of the characteristics of an enzyme, but is used up in the oxidation process. Its action is specific, no substance having been found which can take its place. Photophelein occurs in various extracts of luminous and non-luminous animals, including *Cypridina*. When a *Cypridina* ext. containing luciferin and luciferase is allowed to stand, the luciferin is not completely oxidized, but some of it is bound by other substances in the ext. Photophelein is able to free this bound luciferin probably by displacing it in a manner similar to saponin which will displace luciferin and luciferase from colloidal  $\text{Fe}(\text{OH})_3$  because it is more strongly adsorbed than the latter substances. The oxidation of luciferin is a reversible process involving the reaction  $\text{luciferin} \rightleftharpoons \text{oxyluciferin}$ . Oxyluciferin does not decompose when the partial pressure of O is greatly reduced. It is believed that the oxidation of luciferin to oxyluciferin is similar to that of the leuco base of methylene blue to the blue dye. The following biological substances will reduce oxyluciferin to luciferin: Bacterial or yeast cultures, ground frog muscle, milk, blood of the horseshoe crab (*Limulus*) which has been allowed to stand till bacteria develop and ext. of *Cypridina*, the latter due to the presence of reductases. Chloroform, toluene and thymol have a destructive action on these reductases. A *Cypridina* ext. will not reduce methylene blue or nitrates even in the presence of  $\text{CH}_3\text{CHO}$ , probably because the oxyluciferin present is more readily reduced and therefore is affected first. Oxyluciferin is also reduced by the following inorganic substances:  $\text{H}_2\text{S}$  (incompletely) and hydrogen from palladium black and  $\text{NaH}_2\text{PO}_2$ . Sulfur dioxide or oxides of nitrogen are ineffective. Reduction is favored by weak acids such as  $\text{H}_2\text{CO}_3$  and dilute  $\text{CH}_3\text{COOH}$ ; alkali hinders reduction. Crude luciferin and oxyluciferin are pptd. from solns. by satn. with  $(\text{NH}_4)_2\text{SO}_4$  or  $\text{MgSO}_4$ , but not by  $\text{NaCl}$ . Picric acid gives only an opalescence. They are nearly completely pptd. by phosphotungstic acid, but not by acetic acid or  $\text{CO}_2$ . Both luciferin and oxyluciferin will pass through porcelain filters and parchment or collodion membranes. They are sol. in absolute  $\text{EtOH}$ , but insol. in ether and benzene, are not digested by pepsin-HCl, Merck's pancreatin in neutral solution, or erepsin. Oxyluciferin is partially pptd. by basic Pb acetate and tannic acid. It will not reduce Fehling's, Barfoed's, Nylander's or Knapp's reagent. It apparently does not contain an aldehyde group. Cf. *C. A.* 11, 1212.

CHAS. H. RICHARDSON.

**The photic sensitivity of *Ciona* intestinals.** SELIG HECHT. *J. Gen. Physiology* 1, 147-66(1918).—*Ciona* responds to an increase in the intensity of illumination by means of a local reaction or by a retraction reflex of the body as a whole. The photosensitive area is the intersiphonal region containing the neutral mass. The reaction time to light is composed of a sensitization period of exposure to light and a latent period during which *Ciona* does not need to be illuminated in order to react to the stimulus received during the sensitization period. The duration of the reaction time varies inversely as the intensity; the latent period is constant. The relation between the sensitization period and the intensity follows the Bunsen-Roscoe law. When the animal has become adapted to darkness, the reaction time to light is at first large, then decreases till a constant minimum is reached. A photochem. system is proposed to account for the observed phenomena. This system, which involves a reversible reaction, includes a photosensitive substance and its precursor. The dynamics of the reaction follow closely the peculiarities of the photosensitivity of *Ciona*. In order to produce a reaction, a constant ratio must be reached between the amt. of sensitive substance broken down by the stimulus and the amt. previously broken down. The results of regularly repeated stimulation gave no evidence of a learning process or of the presence of a "higher behavior," but followed the requirements of the photochem. system suggested (cf. *C. A.* 12, 2097).

CHAS. H. RICHARDSON.

**Reversal of reaction by means of strychnine in planarians and starfish.** A. R. MOORE. Rutgers College. *J. Gen. Physiol.* 1, 97-100(1918).—In the marine flat-worm *Bdelloura* and in the starfish, *Asterias forbesii*, previous exposure to a 1:10,000 soln. of strychnine sulfate reverses the reciprocal inhibition on stimulation. The nervous systems of these invertebrates function like those of the earthworm and vertebrates. "It would seem that strychnine acts upon some chem. component of the neuron which is always present in synoptic structures but which also occurs in the simpler neurons of lower forms. The fact that strychnine is without this characteristic effect on such forms as medusa and sea anemone, indicates that the nervous systems of the starfish and planarian have chem. affinities with the vertebrates which the celerates do not possess."

JOSEPH S. HEPBURN.

**Natural and artificial parthenogenesis in animals.** D. WARD CUTLER. Victoria Univ. *Mem. Manchester Lit. Phil. Soc.* 62, Part 1, Memoir No. 2, 42 pp.(1918).—This review is essentially biological. However, the use of reagents in the production of artificial parthenogenesis is described and the theories based on this phenomenon are summarized. A 5 page bibliography is appended.

JOSEPH S. HEPBURN.

## 12. FOODS.

W. D. BIGELOW AND F. F. FITZGERALD.

**Accuracy in commercial grading of opened eggs.** M. K. JENKINS AND NORMAN HENDRICKSON. U. S. Dept. Agr., *Bull.* 391, 26 pp.(1918).—Of interest to the food chemist. Cf. *C. A.* 12, 1572, 2389.

JOSEPH S. HEPBURN.

**Growing lupines with a low alkaloid content (RÖMER) 11D., Rape straw as a paper and fodder material (HEUSER, BLASWEILER) 23.**

**Milk- and cream-ripening and pasteurizing apparatus.** W. R. NICOLL, JR. U. S. 1,285,330, Nov. 19.

**Baking-powder.** H. D. THATCHER. U. S. 1,286,145, Nov. 26. A baking-powder is formed of cream of tartar 67,  $\text{NaHCO}_3$  30, milk sugar 4 and finely powdered casein 4-10 parts.

## 14. WATER, SEWAGE AND SANITATION.

EDWARD BARTOW AND W. F. MONFORT.

**A comparison of the permanganate methods for the determination of required oxygen.** JOHN H. SACHS. *J. Ind. Eng. Chem.* 8, 404-6(1916).—This paper has been previously overlooked through an error.

E. J. C.

**Oxygen demand of sewages.** F. W. BRUCKMILLER. *J. Ind. Eng. Chem.* 8, 403-4(1916).—This paper has been previously overlooked through an error.

E. J. C.

**Softening water.** F. BLUMENTHAL. U. S. 1,285,603, Nov. 26. A  $\text{H}_2\text{O}$ -softening reagent is prepd. by pptg. an Fe compd. from a soln. of  $\text{FeCl}_3$  or other Fe salt by the action of water-glass, and, subsequently, treating the ppt. thus formed with a boiling soln. of  $\text{Na}_2\text{CO}_3$ ,  $\text{NaOH}$ ,  $\text{K}_2\text{CO}_3$  or  $\text{KOH}$  to increase its base-exchanging properties.

**Apparatus for purifying water by treatment with gases such as chlorine.** C. F. WALLACE and M. F. TIERNAN. U. S. 1,285,491-2, Nov. 19.

**Purifying sewage.** W. JONES. U. S. 1,286,017, Nov. 26. Air is used, successively, for treating sewage containing sludge in different receptacles, and accumulated "activated" sludge is used in the treatment of raw sewage. Cf. C. A. 12, 1326.

## 15. SOILS, FERTILIZERS AND AGRICULTURAL POISONS.

J. J. SKINNER.

**Soils of southern New Jersey and their uses.** J. A. BONSTEEL. U. S. Dept. Agr., *Bull.* 677, pp. 77(1918).—A detailed soil and crop survey of a number of areas in southern New Jersey. Maps are given showing the selective uses of soils for specific crops.

J. J. SKINNER.

**Critical contributions to the description of the "red earth" in the Mediterranean region.** PAUL EHRENBURG. *Intern. Mitt. Bodenk.* 6, 277(1916); *Biedermanns Zentr.* 47, 239-40(1918).—A criticism of some of E. Blanck's views (*Landw. Vers. Sta.* 87, 251(1915); *Biedermanns Zentr.* 45, 149(1916)). B. does not state whence the diffusing iron solns. come nor does he sufficiently value the influence of temp. "The contribution of material by the wind may have exerted a not unessential influence on the origin of the red earth."

ALBERT R. MERZ.

**A coating on sand grains and other fine particles which hinders wetting.** ORTO NOLTE. *Intern. Mitt. Bodenk.* 6, 347(1916); *Biedermanns Zentr.* 47, 240(1918).—The view of H. Dèvaux (*Compt. rend.* 162, 197(1916)) that the difficulty of wetting such soil particles is due to envelopment by org. matter of the nature of resin or wax is opposed. This phenomenon has been shown by P. Ehrenberg and K. Schultze (*C. A.* 9, 1142) to be due to the adsorption of air.

ALBERT R. MERZ.

**The preservation of nitrogen in liquid manure.** VOGEL. Leipzig. *Mitt. Deutsch. Landw. Ges.* 1917, p. 690; *Biedermanns Zentr.* 47, 201-3(1918).—N can be retained by mechanical contrivances or by means of chem. agents. In agr. practice  $\text{NaHSO}_4$  deserves first place as a preservative. Liquid manure preserved with it gave excellent results on meadows and with rye, potatoes and beets. Equal quantities of gypsum and bisulfate may be used to avoid the caustic action of the acid sulfate. The addition of 1 to 2% of a fluid containing formaldehyde and phenol, obtained as a by-product in the Bakelite industry, prevented loss of N in urine. Liquid manures thus treated did not injure germination in any way. A mixt. of  $\text{Na}_2\text{SO}_4$  and gypsum, obtained by the treatment of  $\text{NaHSO}_4$  with CaO, limited the loss of N from urine to 57%, urine not so treated losing 77.6% of its N.

ALBERT R. MERZ.

**Determination of the value of agricultural lime.** S. D. CONNER. *J. Ind. Eng. Chem.* 10, 996-9(1918).—The value of agricultural limes was detd. by means of (1) the acid-sol. Ca and Mg, (2)  $\text{CO}_2$  detn. with boiling HCl, and (3) by digesting in standard acid and titrating the excess acid. In pot expts. with acid soils lime minerals were found effective for crop production in the following order, the highest being placed first: Calcite, dolomite, magnesite, wollastonite, rock phosphate, serpentine, enstatite and gypsum. Soil acidity was decreased by the minerals in the following order: Magnesite, dolomite, calcite, wollastonite, serpentine, rock phosphate, gypsum and enstatite. It is stated that the results indicate that the value of agricultural lime is in accordance with its power to neutralize acid rather than its content of CaO, MgO or  $\text{CO}_2$  and that the titration method is most reliable for detg. value of lime.

J. J. SKINNER.

**Analysis of experimental work with raw rock phosphate as a fertilizer.** W. H. WAGGAMAN, C. R. WAGNER AND R. F. GARDNER. U. S. Dept. Agr., *Bull.* 699, pp. 118(1918); cf. C. A. 12, 1492.—A review of the experimental results secured with

rock phosphate as a fertilizer, especially the data secured by the state experiment stations. It is concluded that the conventional laboratory methods for detg. the availability of  $P_2O_5$  in various phosphates do not necessarily serve as an index to its availability under soil conditions. The effectiveness of raw rock phosphate depends upon the fineness of material, thorough distribution in the soil, liberal amts. and thorough cultivation. On most soils raw rock phosphate produces an increase in yield of many crops the first year. Decaying org. matter in the soil increases the effectiveness of ground rock phosphate. The response of crops to acid phosphate is quicker than to ext. basic slag or raw rock phosphate. Acid phosphate has proved superior to raw rock phosphate in most cases.

J. J. SKINNER.

**Alteration of lime-nitrogen on storage.** J. P. VAN ZYL. *Z. angew. Chem.* 31, I, 203-4(1918).—The author mentions the case of a heap of lime-nitrogen which, notwithstanding the fact that it lay in storage for  $2\frac{1}{2}$  years, remained in a remarkably fresh state. It still contained a high percentage of total N (14.64%) and more than 90% of this could be extd. with hot water. From the total N which was found in the ext., more than 75% was still present in the initial state of cyanamide and only 1.6% had been transformed into dicyanodiamide. The rest was at all events present in a form not prejudicial to plants (urea, etc.).

TH. VERHEGGEN.

**Grain-sorghum experiments in the Panhandle of Texas.** C. R. BALL AND B. E. ROTHGEB. U. S. Dept. Agr., *Bull.* 698, pp. 91(1918).—Agronomic data for the various varieties are given.

J. J. SKINNER.

**Phosphate rock in 1917 (STONE) 18.** Potassium compounds from flue dust (U. S. pat. 1,285,152) 18.

**LLOYD, S. L.: Mining and Manufacture of Fertilizing Materials and their Relation to Soils.** New York: D. Van Nostrand Co. 153 pp. \$2.00.

**SORNAY, P. DE: Traité pratique d'analyses agricoles.** Port Louis, Mauritius: Mauritius Stationery & Printing Co., Ltd.

**VON WOLZOGEN KÜHR, C. A. H.: De Microbiologie van de Bodemréductie.** Nederlandsch-Indie: Archief voor de Suikerindustrie. 60 pp.

**Fertilizer from potassium-bearing silicates and sodium phosphate.** W. GLAESER. U. S. 1,285,122, Nov. 19. K-bearing silicates such as feldspar are heated to about  $800^\circ$  and then suddenly cooled to facilitate comminution, the resulting material is ground to 100 mesh, mixed with 25% of Na phosphate and this mixt. is heated to above  $1000^\circ$  to produce a mixt. containing K phosphate.

**Treating potassium-bearing silicates.** W. GLAESER. U. S. 1,285,121, Nov. 19. K-bearing silicate is first heated in lump form to about  $800^\circ$  and suddenly cooled and then ground and the resulting finely divided material is mixed with coke and with about 30% of lime, and this mixt., after being briqueted, is heated with steam and air at a temp. above  $700^\circ$  to produce a mixt. containing  $K_2CO_3$  and suitable for use as a fertilizer.

## 16. FERMENTED AND DISTILLED LIQUORS.

ROBERT WAHL.

**Sweet white wines.** L. M. AND E. V. *Bull. soc. agriculteurs France* 1918, 241-2. —A must of 11.5° B. (containing about 200 g. sugar per l.) or more fulfills the conditions necessary for the production of semi-dry sweet white wines. The wines produced

from musts containing less sugar are not well balanced and are more subject to a second fermentation. To prepare sweet wines from musts poor in sugar, fermentation of a quantity of such must must be stopped when it reaches 5° of alc., by adding 40 g. of  $\text{KHSO}_4$  per 100 l., racking the half fermented wine several days later, and preserving it in casks in a cool place. The casks must be well fumigated with burning S before use and they must be kept full. The half fermented must is then added to a completely fermented wine in quantity ascertained by trial. The procedure of securing well balanced sweet wine from musts of 11.5° B. is described. ALBERT R. MEYER.

**Beer.** E. MONFANG. U. S. 1,286,055, Nov. 26. During a substantial part of the main fermentation, the wort is treated with 2 to 3% by vol. of yeast at a temp. of 0-6° to decompose a substantial portion of the sugar in the wort without materially affecting the albuminoids.

**Brewing.** H. BOULARD. Brit. 119,833, May 7, 1918. To dispense with malt, the wort is saccharified by means of a mucor such as the mucor Boulard No. 5 described in 25,406, 1913 (C. A. 9, 1223), the hops being added before saccharification. The grain is first boiled under pressure, organic acids being added if necessary, to break up the grains and transform the starch into sol. starch and dextrin. The pressures employed and the time of boiling depend on the kind of beer which it is desired to produce. Tartaric acid is stated to give the best results, HOAc coming next. Hops are then added, preferably in two or more stages, and boiling is continued to "break" and sterilize the wort. The wort is then transferred to another vat and cooled to 38-40°, and the saccharifying mucor is introduced. The wort is rapidly cooled to ppt. nitrogenous matters, having been previously boiled if necessary. The mucor may be introduced as a "bacteriological culture" or may be cultivated in a vat from a quarter to a tenth the size of the saccharifying vat. Fermentation may take place in the saccharifying vat or in a sep. vat as desired.

## 17. PHARMACEUTICAL CHEMISTRY.

W. O. EMERY.

An institute for coöperative research as an aid to the American drug industry. *J. Ind. Eng. Chem.* 11, 59-69 (1919).—Discussion of the proposed institute (cf. symposium in *Ibid* 10, 969-76) by CHAS. J. LYNN, President of the Am. Drug Manufacturers Assoc.; by A. R. L. DOHME, J. K. LILLY, WM. JAY SCHIEFFELIN, FRED B. KILMER, and CHAS. G. MERRELL, manufacturers of drugs; by H. A. B. DUNNING and A. D. THORBURN pharmaceutical chemists; by JACQUES LOEB, PAUL A. LEWIS and E. K. MARSHALL, JR., connected with research institutes and organizations; and by REID HUNT, HENRY G. BARBOUR, H. V. ARNY, HUGH MCGUIGAN, ROBERT A. HATCHER and TORALD SOLLMAN, university men. E. J. C.

**Isotonic coefficients.** WM. A. KNIGHT. *Chemist Druggist* 90, 693 (1918).—"The isotonic coefficients, *i. e.*, the numbers expressing the relative osmotic pressures exerted, by mol. proportions of the different classes of compds. in dil. soln. are as follows: Sugars, 2; K and Na salts of monobasic acids, 3; K and Na salts of dibasic acids, 4; K and Na salts of tribasic acids, 5; alk. earth salts of monobasic acids, 4." These numbers can be used in the calcn. of amts. of various substances to use in the prepn. of isotonic solns. The calcn. can also be made from the partial coeffs. of the constituents, allowing 2 for every acid radical, 1 for every atom of alkali metals, and 0 for every atom of divalent metal; *e. g.*, to calc. the amt. of  $\text{MgSO}_4$  necessary to make a soln. isotonic with a soln. of NaCl the ratio would be  $\text{MgSO}_4:\text{NaCl}::246.5:58.5::2:3$ , *i. e.*, for every 2 × 58.5 g. NaCl, 3 × 246.5 g.  $\text{MgSO}_4$  would be required. C. O. EWING.

**Derivatives and oxidation products of the alcohols of the paraffin series found in essential oils.** C. T. BENNETT. *Perf. Essent. Oil Record* 9, 115-7(1918).—A compilation of their occurrence and properties. C. O. EWING.

**Estimation of pulegone and other ketones in oil of pennyroyal.** C. T. BENNETT. *Perf. Essent. Oil Record* 9, 208(1918).—The neutral sulfite process is the only practical method at present known for the estn. of ketones in oil of pennyroyal; the results include both pulegone and menthone. Expts. have shown that the absorption in the case of oil of pennyroyal is much slower than in the cases of dill and caraway oils and that instead of 1 hr. of shaking, at least 3 hrs. is required to obtain good results. An oil showed 44% ketones after 1 hr., 58% after 2 hrs., and 82% after 3 hrs.; another showed 50% after 1 hr. and 88% after 3 hrs. Parry's statement that oil of pennyroyal contains at least 80% of ketones is thus confirmed. C. O. EWING.

**Chemistry of the constituents of volatile oils.** C. T. BENNETT AND C. HOLLINS. *Perf. Essent. Oil Record* 9, 128-62(1918).—"A summary of our present knowledge of the terpenes and their derivs." I. Aliphatic series: (a) Terpenes, (b) Terpene alcs., (c) Terpene aldehydes and ketones, (d) Sesquiterpenes, (e) Sesquiterpene alcs, (f) Sesquiterpene ketones. II. Bicyclic terpenes. III. Monocyclic terpenes (menthadienes). IV. Terpenes of the meta series. V. Terpene alcs. and ethers. VI. Bicyclic terpene ketones. VII. Monocyclic terpene ketones. The paper contains 19 tables of phys. properties of terpenes and derivs. and 123 graphic formulas. C. O. EWING.

**Can *Gentiana asclepiadea* L. be used as a substitute for *Gentiana lutea*? O. HOYER AND R. WASICKY. *Pharm. Post* 51, 145-6(1918); *Chem. Zentr.* 1918, I, 940-1.—*Gentiana asclepiadea* contained only half as much gentiopicrocin as is reported for *G. lutea*. Organoleptic tests also showed that the latter is twice as bitter as the former; consequently when used as a substitute for *G. lutea* twice as much drug is required. Gentiopicrocin has no therapeutic activity against malaria. C. O. EWING.**

**Occurrence of allantoin in rhizome of *Symphytum officinale* and other Borraginaceae.** ALFRED VOGL. *Pharm. Post* 51, 181-4(1918); *Chem. Zentr.* 1918, II, 36.—Allantoin crystals were found in the tissue of cross sections of the rhizome of *Symphytum officinale*. Directions are given for their identification. The crystn. occurs best when a section is mounted in EtOH to which 20% of glacial AcOH has been added, and the cover glass is sealed with paraffin. The allantoin content varies with the season, being highest through the winter and lowest in the summer. None was found in *S. tuberosum*, *S. cordatum*, *S. caucasicum* and other Borraginaceae. C. O. E.

**Stability of digitalis preparations of commerce.** RAPP. *Pharm. Zentr.* 58, 479-81 (1917); *Chem. Zentr.* 1918, I, 231-2.—*Rana temporaria* is superior to *R. esculenta* for testing digitalis preps. All samples to be tested should be evapd. to dryness on a water bath and taken up in 25% alc.; all dilns. should also be made with 25% alc. The test should be carried out by always injecting 0.015 cc. of soln. per 1 g. of body wt. of frog, the concn. of the soln. being suitably varied. A number of German comm. preps. showed a high degree of stability. Cf. C. A. 9, 1527. C. O. EWING.

**Lt.-Col. E. F. Harrison.** *Nature* 102, 210-1(1918).—Obituary. A. R. M.

E. J. C.

**The economical production of 53° B<sub>é</sub>. sulfuric acid from sulfur dioxide.** ALBERT HUTIN. *Rev. prod. chim.* 21, 275 (1918).—To produce 53° acid, SO<sub>2</sub> is bubbled through either 60-62° H<sub>2</sub>SO<sub>4</sub> or the ordinary mixt. of 50° acid and HNO<sub>3</sub>, or water. The app. used consists of 7 parts. First, the purifier, which consists of a volvic lava chamber lined externally with sheet Pb, and divided internally into 2 superimposed compartments by a volvic lava plate, pierced with openings, each one having a stoneware tubulure, 18 cm. in diameter, covered by cap. SO<sub>2</sub> enters through these tubulures, bubbling through a layer of 50° acid, 5 mm. thick. This serves to remove all dust from the gas. The gas, leaving the purifier, encounters the nitrous gases, produced in the second part of the app., the nitrous gas generator. This is a chamber in which are placed cylindrical iron pots, enclosed in sheet-iron casings, heated individually. The pots can be easily removed, cleaned and recharged with acid and niter. The mixed gases now enter the third part of the app., known as the condenser-concentrator. This is a cylindrical tower of the Glover type, but without any interior packing, 7 m. high and 1.5 m. in interior diameter. The lower half is made of volvic stone lined externally with sheet lead, while the upper half is of lead, so that the hot gases entering the tower are not destructive to it. The tower is divided into sections by twelve plates, containing openings covered with caps. A mixt. of 50° H<sub>2</sub>SO<sub>4</sub> and nitrous acid flows down the tower, meeting the SO<sub>2</sub>, which is transformed into H<sub>2</sub>SO<sub>4</sub>. 62° acid is obtained. This acid collected in coolers, where it is cooled from 140-160° to 15°. The gases coming from the condenser-concentrator pass through a separator, in which weak H<sub>2</sub>SO<sub>4</sub> is circulated and a further recovery of 53° H<sub>2</sub>SO<sub>4</sub> is made. The gases then pass through another tower where 50° H<sub>2</sub>SO<sub>4</sub> is obtained and finally through a Gay-Lussac tower.

ISMAR GINSBERG.

**Graph for acid mixing.** E. C. CRAVEN. *Chem. News* 117, 217-8 (1918).—In establishments where H<sub>2</sub>SO<sub>4</sub> is used largely and where mixts. of oleum and C. O. V. are frequently made, a simple device is suggested for detg. graphically the proportions of the two acids to use to obtain an acid of given concn. The device consists of a wooden panel sliding between two scales, one for oleum in % SO<sub>3</sub> and the other for C. O. V. in % H<sub>2</sub>SO<sub>4</sub>, whereby it is possible to read off the desired quantities directly.

ISMAR GINSBERG.

**A new bleaching powder for use in hot climates.** T. J. RETTIE, J. L. SMITH and J. RITCHIE. *J. Soc. Chem. Ind.* 37, 392R (1918).—At 37° bleaching powder loses 96% of its available Cl in 8 weeks, and at 45° the same loss occurs in 2 weeks. The loss is due to the moisture contained in the powder. By mixing freshly burnt quicklime with com. bleaching powder, to the extent of 10-15% excess over the amt. calcd., the keeping qualities are much improved, and there is a decreased tendency toward the formation of Ca(ClO<sub>3</sub>)<sub>2</sub>. 70 parts of bleaching powder with 34% available Cl and 9.7% H<sub>2</sub>O were mixed with 30 parts of quicklime and the dry mixt. tested 23% available Cl.

A sample kept in a sealed tube for 15 weeks at 45° tested 22% available Cl. There was 0.52% chlorate at the start and 1.2% at the finish of the expt. R. B. ROZ.

**Annual Report of the Society of Chemical Industry on the Progress of Applied Chemistry.** London: Harrison & Sons. Vol. II. 537 pp. 6s. 6d. Cf. C. A. 12, 407.

DUBREISAY, RENÉ: *La chimie élémentaire des ingénieurs, des industriels et des constructeurs.* Paris: Dunod et Pinat. 307 pp. 10 fr.

**Mineral Industry for 1917.** Vol. XXVI. Edited by G. A. Roush and A. Butts. New York: McGraw-Hill Book Co. 928 pp. \$10.00.

**Phosphoric acid.** W. H. ALLEN. U. S. 1,285,575, Nov. 26. In the manuf. of  $H_3PO_4$  a mixt. of fuel, phosphates and  $SiO_2$  is conveyed into a combustion chamber containing  $H_2O$  vapor, by means of a blast of air. The mixt. used may, *e. g.*, be composed of phosphate rock, sand and coke.

**Sulfuric and hydrochloric acids.** H. V. WELCH. U. S. 1,285,856, Nov. 26.  $SO_2$ , Cl and  $H_2O$  vapor are caused to react at such a temp. (preferably about 230°) as to produce  $H_2SO_4$  in vapor form in mixt. with HCl gas and the resulting mixt. is cooled to such a temp. as to effect condensation of substantially all the  $H_2SO_4$  at a definite concn., depending on the temp. of condensation, in the form of finely divided suspended particles and the latter are then pptd. electrically to sep. them from the HCl. When condensation is effected in stages,  $H_2SO_4$  of a strength of about 95% is obtained in the initial condensation.

**Apparatus for concentrating sulfuric acid.** J. PATTEN. U. S. 1,286,080, Nov. 26. Acid to be concd. is fed successively through a series of Pb-lined chambers which are heated interiorly by steam coils and in which a vacuum is maintained to distil off the  $H_2O$  at a low temp. The pat. relates especially to the construction for supporting the upper part of the Pb lining to prevent its premature deterioration. U. S. 1,286,188 relates to a generally similar app. for the same purpose.

**Alkalies and alumina from feldspar and similar minerals.** F. A. RODY. U. S. 1,285,796, Nov. 26. Feldspar, leucite or a similar mineral or rock is first treated with a basic alkali compd., such as  $K_2CO_3$  or KOH, to combine with the silicate a greater proportion of alkali than that naturally present and the product is heated to a sintering temp., together with CaO or  $CaCl_2$  in proportion to form orthosilicate of Ca and at the same time to form a  $H_2O$ -sol. combination of the alkali and alumina.

**Alkali chromates.** SOC. INDUSTRIELLE DE PRODUITS CHIMIQUES. Brit. 119,647, Jan. 25, 1918. Crude alkali chromates, or alkali chromate fusion products, with or without the addition of a reagent such as chalk, and in presence or absence of  $H_2O$ , are freed from alkali hydroxides by extg. the hydroxides with an org. solvent such as Et or Me alc. or acetone, which is afterwards distd. off. Any alkali ferrite present may be destroyed by the action of steam before or after the treatment with the solvent. Alkali hydroxides, carbonates, aluminates, or silicates are removed from the chromates by the action of  $CO_2$ , in presence or absence of  $H_2O$ , the products of decompn. of the impurities being insol. while the chromates are unchanged. It is stated that the 2 treatments may be combined.

**Bismuth salts.** N. BUSVOLD. Brit. 119,659, Sept. 30, 1918. Bi salts are sepd. from impurities commonly associated with Bi and Bi is obtained in soln. and may be recovered in the metallic form by pptn. with Zn, by reduction of the oxychloride or by electrodeposition. A Bi ore may be dissolved in HCl and the metals completely pptd. by  $H_2S$ , the ppt. being then treated with a further quantity of the crude soln. which

produces a pure soln. of  $\text{BiCl}_3$ , leaving the As, etc., as sulfide. When a  $\text{Bi}_2\text{S}_3$  ore is treated with an acid ( $\text{HCl}$ ,  $\text{HF}$ , or other acid) the evolved  $\text{H}_2\text{S}$  may be used to effect the pptn. of the crude sulfide. The sulfide ore may be completely dissolved in acid, the soln. being then treated with more of the ore or with another sulfide. As sulfide will then be first pptd. Or a quantity of  $\text{Bi}_2\text{S}_3$  ore may be treated with less than enough acid to dissolve it, when a Bi salt is obtained, leaving As sulfide undissolved.

**Nitrates from sulfides and nitric acid.** W. O. SNELLING. U. S. 1,285,824, Nov. 26.  $\text{Ba}(\text{NO}_3)_2$  is prepd. by spraying  $\text{HNO}_3$  into a soln. containing BaS, spreading the mixt. into thin sheets and maintaining sub-atmospheric pressure above the liquid to remove  $\text{H}_2\text{S}$  as fast as formed. Other nitrates such as  $\text{Sr}(\text{NO}_3)_2$  may be similarly prepd. from the corresponding sulfides. Removal of  $\text{H}_2\text{S}$  avoids reduction of  $\text{HNO}_3$  and consequent formation of  $\text{NH}_4\text{NO}_3$ .

**Magnesium carbonate.** B. B. GRUNWALD. U. S. 1,285,683, Nov. 26. Light  $\text{MgCO}_3$  is prepd. by sepg. dead burned magnesite from light calcined magnesite by sedimentation in  $\text{H}_2\text{O}$  and then carbonating the hydrated magnesia.

**Potassium compounds from flue dust.** E. W. HASLUP. U. S. 1,285,152, Nov. 19. Crude K compds. suitable for use in fertilizers are extd. from flue dust containing K sulfides and silicates by treating the dust with a soln. of  $\text{MgCl}_2$  to decompose the K sulfides present and to ext. the sol. K compds. and then digesting the residue with hydrated  $\text{CaSO}_4$  to convert the K silicates into sulfates. The process is especially adapted for treating elec. pptd. dust from cement kilns.

**Xylolith.** E. WALLIN. Swed. 43,761, Mar. 6, 1918.  $\text{Mg}(\text{NO}_3)_2$  is employed, instead of  $\text{MgCl}_2$  or  $\text{MgSO}_4$ , in the manuf. of xylolith.

**Hydrogen.** C. T. THORSSELL and H. L. R. LUNDEN. Brit. 119,591, Jan. 9, 1918. In the manuf. of H by alternately oxidizing and reducing Fe by steam and reducing gas, resp., the Fe material used is impregnated with compds. of alkali metals in order to retain the activity of the Fe. E. g., Fe sponge may be soaked in a strong soln. of  $\text{NaOH}$  or  $\text{Na}_2\text{CO}_3$  and then dried, or the Fe sponge may be pulverized, mixed with  $\text{Na}_2\text{CO}_3$  and  $\text{H}_2\text{O}$ , pressed into small briquets, and dried.

**Purifying and drying hydrogen.** C. A. PFANSTIEHL. U. S. 1,286,088, Nov. 26. The pat. relates especially to an app. which is designed for purifying excess H which has become slightly contaminated with O and  $\text{H}_2\text{O}$  vapor generated in reduction of  $\text{WO}_3$  by H.  $\text{CaCl}_2$  is used to remove  $\text{H}_2\text{O}$  and hot Cu may be employed for removing the O from the H, which may then be re-used, in a cyclic system, for reducing a further portion of  $\text{WO}_3$ .

**Extracting iodine and other chemical products from seaweeds by dry distillation.** J. A. W. BREDEBERG. Can. 187,721, Dec. 3, 1918. Iodine, etc., are extd. from seaweed by dry distn. in a closed retort. The gases are passed through a condenser and the uncondensed gases are passed through a metal salt which will absorb the volatile I and Br. The residue in the retort is soaked with water and the dissolved salts are sepd.

**Sulfur in globular form.** R. P. PERRY. U. S. 1,285,358, Nov. 19. S in the form of small, globular bodies is prepd. by fusing (e. g., the S of subterranean S deposits by the action of superheated  $\text{H}_2\text{O}$ ) and then, before the fused S has become solidified, injecting it in the form of a spray into a cooling medium such as air.

**Decolorizing carbon.** R. W. MUMFORD. U. S. 1,286,187, Nov. 26. A material suitable for use in decolorizing sugar solns. or other liquids is formed by slowly and gradually heating a mixt. of moist vegetable material such as peat with granular dolomite and  $\text{MnO}_2$ , first to dry and harden and then to char the material; a max. temp.

of above  $600^{\circ}$  is employed at the end of the heating. The product is a fine-grained C of rapid decolorizing action. Sawdust, bark or wood pulp also may be used.

**Extracting oils, pyridine, etc.** V. Z. REED. Brit. 119,648, May 17, 1918. Oils and other hydrocarbon products, N bases, *e. g.*, pyridine and the like, are extd. from shales, coal, etc., by treating the shale, etc., prior to destructive distn. with the vapors, which may be partially condensed, obtained by the distn. process, and in the presence of an acid added or obtained by distn. The condensation of the vapors is completed in passing through the shale, and the hot condensed liquid dissolves part of the oil, etc., from the shale and this is sepd. from the solid material prior to the feeding of the material to the distn. retort. A suitable app. is specified.

**Cleaning metals.** J. H. GRAVELL. Brit. 119,618, Mar. 22, 1918. A compn. for cleaning Fe and steel for painting consists of  $H_3PO_4$ , alc., and  $Ca_3(PO_4)_2$ . When a freely flowing compn. is required,  $H_2O$  is added. The compn. is especially designed for cleaning metals which have been treated with strong acids. The  $Ca_3(PO_4)_2$  may be replaced by other phosphates such as those of Mg or Ba. Cf. C. A. 12, 1761.

**Impregnating porous material with waxy substances.** R. W. E. MOORE. U. S. 1,286,057, Nov. 26. In forming dielectric material from cloth, paper, wood or other porous material, the latter is moistened with  $H_2O$  and then immersed in the waxy impregnating material, *e. g.*, asphalt, heated to above  $100^{\circ}$ .

**Electrical insulating material.** L. McCULLOCH. U. S. 1,286,043, Nov. 26. Elec. insulation suitable for use in elec. heating app. is formed by coating flakes of mica with a coat of bentonite and  $H_2O$  and pressing and drying the material.

**Electrical insulating composition.** J. ANDERSEN. U. S. 1,285,889, Nov. 26. An insulating compn. suitable for use on cables is composed of powdered talc 50, resin 4 and linseed oil 10%. Shellac also may be used as a binder.

**Adhesive from corn-cobs.** F. B. LAFORGE. U. S. 1,285,247, Nov. 19. Corn-cobs are heated under pressure with  $H_2O$  to cause sepn. and soln. of colloidal matter and the colloidal soln. is sepd. from the residue of insol. materials by pressure and then concd. to a thick sirup, which is adapted for use as an adhesive. The pat. is dedicated to the public for free use.

**Aluminium carbide from aluminium silicates.** I. HØY. Norw. 28,212, Sept. 24, 1917. Silicates are treated at a high temp. in the elec. furnace with  $CaC_2$  in the proportion required for the production of the carbide.

**Compounds of oxygen and nitrogen.** O. GALLARDER and E. PRYTZ. Norw. 28,210, Sept. 24, 1917. A mixt. of O and N is compressed under a pressure of 50 atm., and heated by an incandescent body.

## 19. GLASS AND CERAMICS.

G. E. BARTON, A. V. BLEININGER.

The occurrence of high-grade American clays and the possibility of their further development. H. RISS. *J. Am. Ceram. Soc.* 1, 446-67(1918).—The chief imports have been in glass-pot, crucible and enamel clays from Central Europe, and china and ball clays from England. The present investigation of clay deposits covers the U. S. east of the Mississippi River and parts of Arkansas and Missouri. The study is more geologic than technologic, but practical applications are kept in mind. The various clay deposits of all kinds are described under 5 headings: Atlantic Coastal Plain belt Embayment Area, Piedmont plateau, Coal Measures region, and Missouri flint clay areas. The outlook for further development of American clay deposits is good. Most,

if not all, of the imported clays may be duplicated at home. Where one clay is not satisfactory a blending of two or more may be successful. C. H. KERR.

**Newcomb pottery.** MARY G. SHEERER. *J. Am. Ceram. Soc.* 1, 518-28(1918).—A history and description of the pottery at Newcomb college. The mat glaze most largely used is 0.6 PbO, 0.4 CaO, 0.35 Al<sub>2</sub>O<sub>3</sub>, 1.00 SiO<sub>2</sub> and a good Sn glaze is 0.7 PbO, 0.2 CaO, 0.1 ZnO, 0.15 Al<sub>2</sub>O<sub>3</sub>, 1.75 SiO<sub>2</sub>, 0.3 SnO<sub>2</sub>. Local Louisiana clays are used for body and sagger mixts. Formulas and methods of working are given.

C. H. KERR.

**Preparation and application of enamels for cast iron.** HOMER F. STALEY. *J. Am. Ceram. Soc.* 1, 534-55(1918); cf. *C. A.* 12, 2117.—A detailed description.

C. H. KERR.

**Antimony oxide as an opacifier in cast-iron enamels.** J. B. SHAW. *J. Am. Ceram. Soc.* 1, 502(1918).—The price of SnO<sub>2</sub> is almost prohibitive; since Sb<sub>2</sub>O<sub>3</sub> is equal to SnO<sub>2</sub>, pound for pound, as an opacifier, enamel cost can be reduced about 50%. The only difficulty in using Sb<sub>2</sub>O<sub>3</sub> is in getting good colors. Three series embracing 66 trials are described. *Conclusions:* To produce satisfactory colors in Sb<sub>2</sub>O<sub>3</sub> enamels: (1) use only the purest white Sb<sub>2</sub>O<sub>3</sub>, (2) use a little CaF<sub>2</sub>—not over 5%, (3) maintain oxidizing conditions during smelting—use plenty of NaNO<sub>3</sub>, (4) control color by adding Fe<sub>2</sub>O<sub>3</sub>, MnO<sub>2</sub> and PbO, (5) use Na<sub>2</sub>AlF<sub>6</sub> in small amt.—up to 3% (larger amts. are unsatisfactory), (6) weigh carefully, mix thoroughly and smelt carefully.

C. H. KERR.

**Silica refractories.** DONALD W. ROSS. *J. Am. Ceram. Soc.* 1, 477-501(1918).—Most SiO<sub>2</sub> bricks are made from quartzites of early geologic age and the most suitable are those which range from the slightly porous to the highly metamorphosed impervious rocks with tightly interlocking grains. In thin section under the microscope these quartzites show interstitial impurities (like Fe<sub>2</sub>(OH)<sub>4</sub>) appearing as sharply defined lines between the tightly interlocking SiO<sub>2</sub> grains. Quartzites which crush chiefly along the interstitial lines are apt to yield bricks of higher porosity than those that crush by breaking through the original grains. The porosity of the finished SiO<sub>2</sub> brick depends primarily upon that of the unburned mixt. Heating brick containing large % of unchanged quartz to over 1350° causes undue expansion and gives a punky product, while holding at 1250 to 1350° until conversion is largely accomplished and then raising gradually to higher temps. gives a brick of low porosity and low sp. gr. Sp. gr. is the most important test, but for a comprehensive study detn. should be made of porosity, cold cross-breaking strength, softening temp., load test and microscopic appearance. *Discussion:* R. M. HOWE said one manufacturer controlled burning as follows: burning is stopped when draw trials show 2.40 sp. gr. As the kiln is held the bricks undergo further transformation and when drawn show sp. gr. below 2.38. Chem. compn. is of secondary importance and present data do not justify setting limits for any one impurity. Usually total impurities run from 4.0 to 6.5% If SiO<sub>2</sub> = 94% or more the compn. is satisfactory without reference to any other ingredient.

C. H. KERR.

**Corrosive action of flue dust on firebricks.** WALTER EMERY. *Gas World* 69, 231(1918); *Iron and Coal Trades Review* 97, 460(1918).—The corrosive effects of dust on firebricks are discussed together with the method and app. used in the expts. Abnormal and deleterious conditions were simulated without its being possible, however, to express the results in a quant. manner by wt., measurement, or by graphic diagrams. Analyses of both firebricks and dusts are given. Results of tests show that in general the penetration by the dust is greater in fireclay than in silica brick. In most cases the bond is attacked first and coarser grains last. In silica bricks the depth of penetration is generally less the finer the grain. In the fine-grained bricks the coarser grains and

the bond are both attacked, while in the coarse-grained bricks the bond alone is attacked to any serious extent. It therefore follows that the bond of a silica brick offers the feeblest resistance against a corrosive slag. Under oxidizing conditions iron oxide does not corrode silica bricks to any noteworthy extent, but under reducing conditions ferrous silicate forms and acts as a corrosive flux. In the trials with "bull dog" the silica bricks were far less attacked than the fireclay bricks and generally the iron oxides corrode the fireclay bricks more than the silica bricks. The dusts apparently exert an influence on the conversion of the quartz into the low sp. gr. forms even where the coarse grains have apparently not been penetrated. There is also some evidence that contact with iron oxide in oxidizing flame hastens the conversion of quartz.

J. L. WILEY.

**A pycnometer operated as a volumeter.** H. G. SCHURECHT. *J. Am. Ceram. Soc.* 1, 556-9(1918).—The Seger volumeter is too slow, too difficult to operate and too fragile. A simple form made and operated like a pycnometer is described.

C. H. KERR.

**Design of porcelain insulators from the ceramic standpoint** (GILCHRIST, KLINE-FELTER) 4.

ESCARD, J.: *La nouvelle industrie du verre*. Grenoble, 23 Grande Rue: J. Rey. 120 pp. 5 fr. 40.

## 21. FUELS, GAS, TAR AND COKE.

J. D. PENNOCK.

**Combustion characteristics of coals.** J. G. WORKER. *Elec. Rev. West. Elec.* 73, 849-52(1918).—The type of stoker equipment chosen depends upon load conditions, available coal, draft and conditions of application. For buckwheat anthracite, the overfeed or inclined underfeed types of stoker are best. For mixed coal, up to 50% anthracite, an elaborate mixing scheme is essential and the boiler efficiency drops with increase of anthracite. Eastern semi-bituminous and bituminous coals lend themselves to the overfeed, inclined underfeed and some forms of single retort underfeed type; so the selection depends upon load conditions. Tables show percentage of boiler rating during test, the duration of the test, pounds of coal per sq. ft. grate per hour, CO<sub>2</sub> %, percentage of boiler-, furnace-, and grate-efficiencies based on dry coal, the B. t. u. and temp. of flue gases during combustion of various types of coal. Coke breeze is best burned on a flat grate with medium pressure under the grate. Western lignite is easily handled while that from Texas does not burn satisfactorily with any type of mechanical stoker.

W. H. BOYNTON.

**Reducing difficulties in burning Iowa coal.** T. A. MARSH. *Elec. World* 72, 1166-8(1918).—Iowa coal is bituminous and non-coking and contains high percentages of ash of low m. p. Typical analyses of screenings are given. The chain-grate stoker is best. Extreme width and breadth are needed to provide max. grate area. An extreme amt. of reflecting brickwork and arch insures combustion temps. A typical installation burns Iowa coal at the rate of 175 kg. per sq. m. of grate hourly. Analysis: Moisture 14.05%, volatile matter 31.92, fixed C 28.82, ash 25.21, B. t. u. (dry basis) 9,192. With the same setting coal has been burned at the rate of 146 kg. per sq. m. which shows on analysis: Moisture 11.65%, volatile matter 29.00, fixed C 26.75, ash 32.60, B. t. u. (dry basis) 8,085. A furnace of extreme design with reversed arch to reflect heat and gases forward burns coal showing on analysis: Moisture 19.03%, volatile matter 25.02, fixed C 22.23, ash 33.72, B. t. u. (dry basis) 6,576. Addition of

water some hrs. previous to combustion diminishes sifting through the grate, makes the fuel bed more compact, and the steam generated cracks open pieces of coal, aiding quick combustion. When ash equals 25%, its discharge should be continuous and liberally proportioned. Large grate areas, high draft and long arches are necessary. Existing settings may be improved by application of these principles.

W. H. BOYNTON.

**Exact data on the running of steam boiler plants.** I. D. BROWNLIE, J. COMPTON AND H. W. ROYSE. *Engineering* 106, 481-2 (1918). E. J. C.

**Use of coal in pulverized form.** H. R. COLLINS. *Bull. Am. Inst. Mining Eng.* 1918, 1678-84, 1771-4; cf. C. A. 12, 1344.—A discussion. J. L. W.

**Dry-gas producer.** MAX BRAÜTIGAM. *Stahl u. Eisen* 38, 786-9 (1918).—This dry-gas producer is a tapping producer fed with coke. For slagging the coke ashes basic Martin slags or other slags rich in iron are used, from which pig-iron with a high % of Mn and P is obtained. The dry-gas producer differs from other tapping producers for gasification of coke in that it has neither steam supply nor hearth heating. The dry-gas producer may, in construction, be considered as a small blast furnace (half-blast furnace), in which, however, no part of the CO generated is used for the reduction of iron ores; all the CO is used as fuel for metallurgical or other purposes. A reduction, by CO, of the O compds. which are present in the slag additions does not take place because iron (as Martin or other slag) enters into the producer in an already slagged state. A consumption of CO by reduction of this metallic oxide and a partial transformation into CO<sub>2</sub> consequently does not occur, as also is shown by the small % of CO<sub>2</sub> (0.3 to 0.7%) in the gas. The sepn. of metals from the silicates by means of solid C occurs so extraordinarily rapidly that the use of the mentioned slags instead of other additions may be looked at as a great advantage. The temps. are the same as in blast furnaces. The use of P additions prevents the freezing of the generated P-Fe alloy because of its low point of solidification. A concise description is given of the producer. Slag and metal are tapped off at regular intervals. The producer lasts 13 months; after this time the hearth must be replaced. Throat and bosh are not so strongly corroded and repairs are not so often necessary. *Products of the dry-gas producer:* (1) *The dry gas* is distinguished by a very high content of CO (32.4 to 33.7%), a very low content of CO<sub>2</sub> (0.3-0.7%), and a very low % of moisture (12 g. per m<sup>3</sup>). The calorific value amounts to 1100-1186. The compn. of the gas must be considered to be favorable to the obtainment of a high temp. of combustion, for the combustible part of the gas consists almost entirely of CO (32.4-33.7%), (H<sub>2</sub> = 0.00-0.64% and CH<sub>4</sub> = 0.99-1.79%); the percentage of moisture is very small. The dry gas is practically tar-free—1 kg. coke with 88% C gives 5 m<sup>3</sup> gas—the S content amts. to 0.280%. (2) *The iron:* By the gasification in the dry-gas producer, almost all the iron contained in the added slags and coke ashes is extracted (per ton coke 16.6-43 kg. iron). This iron has a high Mn and P content (Mn = 8.44-10.48; P = 6.85-11.46). (3) *The tapping slag:* The tapping slag was good com-

paratively thin liquid, the color was yellowish green, rarely gray; the structure usually stony, rarely vitreous. It contained only 1-2.5% Fe and 2.7% Mn.

TH. VERHEGGEN.

**Influence of quality of gas and other factors on the efficiency of gas-mantle lamps.** R. S. MCBRIDE, W. A. DUNKLEY, E. C. CRITTENDEN AND A. H. TAYLOR. *Bur. Standards, Tech. Paper* 110, 49 pp.(1918); *Gas Age* 42, 468-70, 519-21(1918).—This paper discusses the various conditions such as gas quality, gas pressure, gas adjustment and air adjustment, which affect the operation of mantle lamps, and describes the methods and app. employed to control these variables and study their sep. effects. The results obtained are given and their application to practical operation is touched upon. Comparisons are made between lean water gas, city rich mixed gas, lean coal gas, and a benzolized city gas in lamps of standard types. These conclusions are drawn: (1) A given fluctuation in gas quality produces less change in the efficiency of operation of lamp with lean gas than with rich gas. (2) If a lamp is adjusted for max. c. p., an increase in the heating value of the gas supplied to it produces a decrease in efficiency; and a decrease in the heating value produces an increase in efficiency. J. L. W.

**Coke handling at Manchester Corporation gas works.** GEORGE FREDERICK ZIMMER. *Engineering* 106, 367-70(1918).—Z. describes the "Ideal" hot-coke handling machine manufd. by Drakes, Ltd., of Halifax. In construction it resembles an inclined elevator or skip-hoist with one bucket. It is so constructed that hot coke or dust never comes in contact with moving parts. The operation is efficient and economical. J. L. W.

**Inclined retort plant at Rome a success.** S. BENT RUSSELL. *Gas Age* 62, 463-6 (1918).—A description of a recently made installation of 5 inclined benches of 6 retorts each of the Parker-Russell type, fully equipped with up-to-date appliances. The plant has a creditable record for economy and efficient operation. J. L. WILEY.

**Apparatus (Poetter type) for the treatment of gas-liquor containing ammonia to obtain ammonium sulfate.** HEINRICH BORNGRÄBER. *Chem. App.* 5, 17-9(1918).—The app. is described and its operation explained. The calcn. of the economy of the work is established. Sketches are included. TH. VERHEGGEN.

**Distillation of tar from Mond gas plant.** A. GATLEY LYON. *Chem. Eng. Mining Rev.* 10, 19-20(1918).—At the Mond gas plant installation at the Sulphide Corporation Works, New South Wales, the tar as received from the plant is stored into a large boiler shell and kept hot by means of steam coils. Mond gas tar, on account of its peculiar physical properties, holds a large amt. of water, a considerable part of which seps. out in this tank and is drawn off from the surface by means of a Dutch syphon. The tar is run from the bottom of the storage tank into a blower egg, from which it is elevated to the dehydrator. This is a round tank about 5.5 × 8 ft., fitted with steam coils, an overflow pipe leading back to the storage tank, and a run-off pipe directly connected with the tar still. Great care must be taken in dehydrating the tar, owing to its strong frothing tendencies. When the tar reaches 120° it is considered safe to charge into the still. The still is of regular design, 6 × 7.75 ft., with a concave bottom of 21 in. depression, and holds 1000 gal. Directly connected with it is a condenser, consisting of a vat containing a 2-in. iron-pipe worm, from which the oil, after condensing, runs into the storage tanks. The still is charged with about 900 gals. of dehydrated tar at about 130°. The tar is heated slowly to 190°, the heat being then increased for 6 or 7 hrs., the exact time depending on the sp. gr. of the oil at the worm end. When the sp. gr. reaches the desired point, the fire is drawn, and superheated steam is blown through the still for a further 2 hrs., it having been turned on soon after the distn. was under way. The steam not only assists mechanically in driving off the oil fumes, but

causes the oil to distil at a lower temp., and cools the pitch. By this time the fire is drawn the water in the condenser is almost up to the b. p. and the distillate is a thick, sticky, semi-solid oil of 1.12 sp. gr. After all the oil has been driven off, the residual pitch is run off at the bottom into coolers and allowed to set. It is later consumed in the gas producer with the coal, giving further quantities of tar, gas and  $\text{NH}_3$ .

J. L. WILEY.

Some applications of physical chemistry in the coal-tar industry. WILBERT J. HUFF. *J. Ind. Eng. Chem.* 10, 1016-19(1918).—The address deals with volume relations in solidifying creosotes and with vapor densities of coal-tar fractions.

J. H. YOUNG.

Cascade-boiler-plant for fractional distillation of coal tar in continuous operation. WERNER BERGS. *Chem. App.* 5, 81-3(1918).—The plant of the Zimmermann and Jansen, G. m. b. H. type in Düren (Rhld) is described and the operation explained. The working of this plant is very simple and economical. Sketches are included.

TH. VERHEGGEN.

Influence of temperature on the decomposition of sodium carbolates and cresylates by carbon dioxide. G. J. DENBIGH. *J. Soc. Chem. Ind.* 37, 306-77(1918).—The fractions of coal tar which contain the bulk of the tar acids are crude naphtha, light oil and carbolic oil, and the crude acids are extd. from these by washing with NaOH soln. The sepn. of the crude acids from the Na salts is effected most economically by decompn. with  $\text{CO}_2$ , thus regenerating  $\text{Na}_2\text{CO}_3$ , which is again causticized and used for the further treatment of fresh oils. In the working of crude carbolic plant, D. noted the apparently abnormal decompn. by the  $\text{CO}_2$ . This was made in a lime kiln and after purification contained 17-20% of  $\text{CO}_2$ . It was found that a small variation in the % had little or no effect on the rate of decompn., so attention was directed to the effect of temp. By bubbling gas through an ordinary cresylate soln. it was evident that decompn. was much more rapid at high temp. than at lower. More careful expts. were then arranged. Phenol with a solidifying point of 40.5°, *o*-cresol solidifying pt. 30°, *p*-cresol solidifying pt. 35.6°, and *m*-cresol were obtained, the purity of the latter being ascertained by Raschig's nitration test as 99.4%. In each case the calcd. amt. was dissolved in 800 cc. of 10% NaOH and the soln. dild. until titration with 0.1  $\text{N}$   $\text{H}_2\text{SO}_4$  showed the soln. to be exactly 2N, with phenolphthalein as indicator.  $\text{CO}_2$  from a Kipp app. was passed through a soln. of  $\text{NaHCO}_3$  and collected in a gas holder. Two and one-half l. were then slowly passed through 100 cc. of the sodium phenoxide soln. This represented an excess of gas. The phenoxide soln. was then shaken with 50 cc. of benzene, in 2 portions; after standing for an hour the benzene sepd. into a well-defined layer. The undecomposed phenoxide was removed and 20 cc. and 10 cc. of 10% NaOH were successively shaken with the benzene soln. to re-form sodium phenoxide. After setting, this was run off, heated to 80°, cooled, decomposed with 30 cc. of 25%  $\text{H}_2\text{SO}_4$ , and the liberated phenol was measured in a graduated cylinder. These expts. were repeated with the same quantities at different temps. and the results plotted. The vols. of  $\text{CO}_2$  were corrected for temp. and pressure, and the temp. of the phenoxide or cresylate soln. regulated by a thermostat. The chief difficulty found in the work was in sepg. the benzene soln., at least 1 hr. being required. The results established are: (1) All the cresols are more easily liberated than phenol. (2) Cresols differ only slightly, *m*-cresol being the most easily liberated, *o*-cresol the least. (3) In the case of both phenol and cresols the decompn. is more complete when warm, and the rate increases more rapidly with the cresols than with phenol. It is possible, to a certain extent, to sep. cresol from phenol by fractional decompn., but like fractional washing, which gives a carbolate containing some cresylate or a cresylate containing some phenoxide, it is by no means as complete as could be desired.

J. L. WILEY.

**Development of the coke industry in Colorado, Utah and New Mexico.** F. C. MILLER. *Bull. Am. Inst. Mining Eng.* 1918, 1693-5.—A discussion (cf. *C. A.* 12, 1920). Mr. C. H. Gibbs gives the history of the coke industry in Utah. The only genuine coking coal found in Utah is the Sunnyside coal. An av. analysis shows for coal and coke, resp.: moisture 1.2, volatile matter 39.13, fixed C 53.69, ash 5.98%; moisture 0.81, volatile 0.83, fixed C 87.36, ash 11, S 0.7-1, P 0.03-0.05%. J. L. W.

**Some economic considerations in coke-oven practice.** W. COLQUHOUN. *Gas World* 69, No. 1794 (Coking and By-products Sec.), 19-20, No. 1798, 21-3(1918). E. J. C.

**By-product coke oven and its products.** W. H. BLAUVELT. *Bull. Am. Inst. Mining Eng.* 1918, 597-614, 1677-8, 1770-1.—While the number of beehive ovens in the U. S. has been steadily decreasing, the number of by-product ovens has increased from 4624 in 1911 to about 7660 in 1917, with 2800 building, making a total of about 10,460 in operation in 1918. The total production of coke in 1917 was estd. at 56,600,000 tons, of which 60% was from beehive ovens and 40% from by-product ovens. (Abstractor's Note: On Nov. 2, 1918, by-product ovens assumed what would appear to be a permanent lead over beehive ovens by a production of 51% of the total.) The superiority of American by-product ovens over those of Europe, from the viewpoint of metallurgical practice, is due to the larger units and larger output per unit, the more extensive use of labor-saving machinery, and the use of silica refractory material which permits of higher heats and shorter coking time. The modern oven will carbonize more than 20 tons per day. In order to meet the requirements for a metallurgical fuel, it is agreed that the coke must be hard, must be resistant to attrition and oxidation, must have an open-cell structure, that is, cells of good size and approx. 50% of cell space, and must be highly combustible. The by-product oven, with its variable mixts. of coal, variable heats, coking time, width of oven, fineness of coal charged, and other controlling factors, not only permits such a control of coke but also allows the use of many coals which would not be suitable with the beehive oven. As the best coals are being progressively exhausted, this latter point becomes more important. In discussing the recovery of by-products, such as tar, benzene,  $\text{NH}_3$ , gas, etc., and their utilization, B. states that the surplus gas, above that used for heating the ovens themselves and the tar obtained in the production of a ton of coke, will furnish the necessary fuel to produce a ton of ingots from an open-hearth steel furnace or 10-15% more iron from a blast furnace than when heated with producer gas. Without considering the value of the other by-products recovered, this illustrates the importance of the by-product oven as a fuel supply to the steel industry. It is hard to suggest any other industry of comparatively recent introduction which does more to conserve the natural resources of our country. J. L. WILEY.

**New ovens at Lambton.** G. P. LISHMAN. *Gas World* 69, No. 1794 (Coking and By-products Sec.), 17(1918).—The 35 Simplex regenerative ovens recently installed are described. E. J. C.

**Fuel mixture.** W. JOITE. U. S. 1,285,208, Nov. 19. A fuel mixt. in block form

is made of clay 22, finely divided bituminous coal 25, coke dust 50 and hydrocarbon oil 3 parts.

**Destructive distillation.** A. L. PEARSE. Brit. 119,700, Oct. 11, 1917. Coal, shale, lignite, etc., are destructively distd. while passing through zones of different temps., and the different gaseous products are drawn off at different levels from the retorts through outlets which are arranged to overhang certain parts of the retorts in such a manner that obstruction of the outlets cannot take place. The heating of the retorts is effected by gas and regeneratively heated air, and the burners and flues are so arranged that the products of combustion pass downward through staggered passages arranged so as to be easily adjustable for varying the heating and for maintaining a uniform heat throughout each horizontal zone. The coke is cooled by the air which passes to the burners. Cool air may be admitted when desired to the flues, and steam may be introduced into the retorts to increase the production of  $\text{NH}_3$ . A suitable app. is specified.

**Gas manufacture.** T. McCLELLAND. Brit. 119,885, Sept. 24, 1917. Gas for engines and the like is formed by the passage of an elec. current between fine granules of C contained in an insulating vessel of porcelain or the like, the granules being moistened with  $\text{H}_2\text{O}$  or other liquid, *e. g.*, an acid or alk. soln. A suitable app. is specified.

**Lampblack from oil-gas refuse.** R. D. PIKE. U. S. 1,285,363, Nov. 19. The C from the carbonaceous refuse product obtained in oil-gas manuf. is recovered for use in the manuf. of C electrodes by washing out tarry and other impurities and then roasting the residue to remove volatile hydrocarbons and comminuting the purified solid residue.

**Retort-furnace for producing illuminating-gas.** P. G. STRASSMANN. U. S. 1,285,833, Nov. 26.

**Emulsions of tar-like substances.** O. LÜHRS. Dan. 23,419, Aug. 22, 1918. Tar is mixed with waste lye from alkali-cellulose manuf.

**Reducing viscosity of petroleum oils.** A. PHILIP. U. S. 1,286,091, Nov. 26. Petroleum oils which are so highly viscous that they cannot be readily pumped for use as fuel are mixed with 8% or less of  $\text{C}_{10}\text{H}_8$  to reduce their viscosity.

**Refining petroleum oils.** R. E. HUMPHREYS. U. S. 1,286,179, Nov. 26. After treatment of petroleum oil with concd.  $\text{H}_2\text{SO}_4$ , the acid sludge is drawn off, leaving a body of oil containing a small amt. of sulfonic acids in soln., the oil is neutralized with  $\text{NaOH}$ , and dil. alc. is employed thereafter to ext. the salts formed.

**Purifying oils.** A. E. DUNSTAN. Brit. 119,751, Nov. 28, 1917. Oils obtained by cracking are purified by slow distn. in the presence of a small proportion of an anhydrous chloride such as  $\text{AlCl}_3$ . The  $\text{AlCl}_3$  may be used in the form of a soln. in an anhydrous solvent such as abs. alc., or may be mixed with a dry inert material.

**Apparatus for cracking hydrocarbons.** E. W. ISOM. U. S. 1,285,200, Nov. 19.

**Apparatus for cracking hydrocarbon oils to produce a motor-fuel.** W. A. HALL. U. S. 1,285,136, Nov. 19. The app. is especially designed for carrying out the process described in U. S. pat. 1,175,910; C. A. 10, 1429.

### 23. CELLULOSE AND PAPER.

A. D. LITTLE.

**Guide to the bleaching of pulp and paper.** JAMES BEVERIDGE. *Paper* 23, No. 8, 11-5(1918).—A description of various types of pulp-bleaching equipment, together with a formula for calcg. the amt. of steam required for bleaching pulp of different densities.

R. B. ROE.

**Chlorinated lime vs. electrolytic bleach.** ANON. *Papier fabr.* 7(1918); *Paper* 23, No. 9, 11-4(1918).—An elaborate series of expts. showed that electrolytic bleach gives a better white than chloride of lime with a saving of 5% bleach. Increasing the alkalinity of bleaching soln. increases the bleaching effect, although the velocity of reaction is decreased. Slightly acidifying neutral or alk. bleach improves the results while strongly acidifying decreases the efficiency. No explanation is advanced for the better results obtained with electrolytic bleach.

R. B. ROE.

**Factors in the measurement of pulp fibers.** JOHN H. GRAFF AND MARIE HODGDON. *Paper* 23, No. 13, 11-5(1918).—The strength and quality of sulfite and sulfate pulps are intimately connected with the length of the fibers. The following procedure is suggested for detg. fiber length: At least 10-20 sq. in. of sample are disintegrated with H<sub>2</sub>O in an Erlenmeyer flask. A small portion is removed to another flask. dild. with H<sub>2</sub>O so that the ratio of fiber to H<sub>2</sub>O is 1:1000, and a small quantity of this soln. is transferred to a test-tube. Three other test-tubes are filled in the same way. With a wide-mouthed dropper a drop is removed and placed on a slide, the water is evapd., and the dry fibers are stained with I-KI soln. The excess stain is carefully removed with filter paper under the dissecting microscope, a drop of CaCl<sub>2</sub> soln. is added and the excess removed. The slide is placed under the dissecting microscope and 25 representative fibers "teased" to the center of the slide so that they lie side by side. The length of these fibers is then measured under a microscope fitted with a micrometer eyepiece. In the same way 2 drops are taken from each test-tube making a total of 200 measurements. The av. fiber length in mm. is detd. and the percentage of fiber lengths of 0-1 mm., 1-2 mm., 2-3 mm., 3-4 mm., and 4+ mm., recorded. The investigation shows that there is no distinct advantage in making over 200 measurements of one sample, and that one operator can prep. 3 samples, make the necessary 600 measurements and plot the results on a chart in 1 day.

R. B. ROE.

**Indirect cooking by forced circulation.** ALBERT E. NIELSEN. *Paper* 23, No. 10, 11-5(1918).—A comparison of the advantages and disadvantages of several well known methods of cooking wood pulp is given.

R. B. ROE.

**Beating tests.** E. SUTERMEISTER. *Paper* 23, No. 14, 11-3(1918).—Using the half-mill beating test, S. repeated the work of Mansfield and Stephenson (cf. C. A. 11, 887) and found that beating sulfite fiber in the presence of various chemicals produced but a very slight increase in strength compared to the results of M. and S., due probably to some unknown factor in the quality of the pulp. Comparative tests on soda and sulfite pulps which were treated with various agents and allowed to age for a definite period, showed that water treatment alone gave a strength increase with soda pulp. With sulfite pulp, soaking in bleach soln. and 2% HCl at first increased the strength but longer soaking showed a decided decrease. Treatment, followed by storage,

with 2%  $\text{CaCl}_2$ , 5%  $\text{NaCl}$ , 1%  $\text{ZnCl}_2$  and  $\text{H}_2\text{O}$ , all produced decided increases in strength. Samples of bleached soda and sulfite pulps which had aged for various periods after bleaching showed no consistent strength variation when sampled at different time intervals. Tests are given showing the importance of making up hand sheets of constant wt. Using the ordinary hand mold, the wt. of the hand sheet will decrease as the stock becomes more hydrated, and correcting for different hand sheet wts. by dividing the bursting strength figure by the wt. of the sheets does not give the same result as when the wt. of the sheets is maintained constant. Attention is directed to the great variation in the size and vol. of different ball mills supposedly of the same dimensions. It is possible this variation may cause the fiber to "knot," and it is necessary to det. by expt. the proper charges if two ball mills are used. R. B. ROE.

**Analysis of sulfite acid.** PETER KLASON. *Pulp and Paper Mag. Can.* 16, No. 46, 47(1918).—A critical study of the common methods for analysis of sulfite cooking acid shows these methods incorrect. A correct method for titration of the acid is proposed and a formula is given for calg. the results obtained. R. B. ROE.

**Rape straw as a paper and fodder material.** E. HEUSER AND T. BLASWEILER. *Papier-Ztg.* 43, 593; *J. Soc. Chem. Ind.* 37, 574A.—The compn. of the rape plant is somewhat similar to that of cereal straw. Analysis showed, on the dry substance, 30.31% cellulose, 24.1% pentosans, 40.06% lignin, and 5.53% ash. A pulp prepd. by the soda process had the compn.: cellulose 55.60%, pentosans 30.50%, lignin 10.10%, ash 3.77%. The pulp so obtained would be suitable for the manuf. of boards. R. B. ROE.

**Log bark (ANON) 29.** A new bleaching powder for use in hot climates (RETTIE, et al) 18. Emulsions of tar-like substances (Dan. pat. 23,419) 21.

**Lockwood's Directory of the Paper and Stationery Trades.** 44th Ann. Ed. Canada: Lockwood Trades Journal Co. \$5.00.

**Cellulose acetates.** H. DREYFUS. U. S. 1,286,172, Nov. 26. Cellulose acetates which are practically insol. in a mixt. of alc. and  $\text{C}_6\text{H}_6$  and also in  $\text{CHCl}_3$  but sol. in acetone of high concn. and also in a mixt. of alc. with  $\text{CHCl}_3$  (such as may, e. g., be made by the process described in Brit. pat. 20,977, 1911 (C. A. 7, 891), are treated with dil.  $\text{HNO}_3$  to render them sol. in a mixt. of alc. with  $\text{C}_6\text{H}_6$ .  $\text{HNO}_3$  of a strength of about 12% is preferably used, at ordinary temp., and the material is tested from time to time to det. its solubilities.

**Cellulose nitro-acetic esters.** J. KOETSCHET. U. S. 1,286,025, Nov. 26. A nitro-acetic deriv. of cellulose is formed by treating cellulose with glacial  $\text{HOAc}$  containing 1-20%  $\text{Ac}_2\text{O}$  together with  $\text{HNO}_3$  and a condensing agent such as  $\text{H}_2\text{SO}_4$ , acetylating the resulting fluid product with additional  $\text{Ac}_2\text{O}$  and then partially saponifying and pptg. the acetylated product. The product thus formed gives solns. of great viscosity.

## 24. EXPLOSIVES AND EXPLOSIONS.

CHARLES E. MUNROE.

**Explosives which are chemically possible.** ALFRED STETTBACHER. *Arch. sci. phys. nat.* 44, 380-1(1917).—Although nitroglycerin is one of the most violent of the explosives in use to-day, it is far from being an ideal explosive, since it develops but about 43% of the energy of combustion which could be set free by the direct oxidation

of its C and H contents. One kg. of nitroglycerin develops 1580 Cal. Better results are obtained by the direct combustion of a hydrocarbon with O as in oxyliquite, 1 kg. of which yields about 2,200 cal. Combinations of hydrocarbons with O in the ozone arrangement (peroxides) are among the most violent explosives known to chemistry.

Examples are ethylene ozonide,  $\begin{array}{c} \text{CH}_2 \\ | \\ \text{CH}_2 \end{array} \text{O}_3$ , and benzene triozone,  $\text{C}_6\text{H}_6(\text{O}_3)_3$ . Their

heats of combustion are not quite equal to that of oxyliquite, but the velocity of decomposition and brisant character of these pure compounds render them more violent, possibly the most violent in existence. By means of  $\text{HClO}_4$  still more powerful explosives can be obtained; glyceryl trichlorate develops 3000 Cal., which is but little less than double that of nitroglycerin. In this compound there is reached the best but also the last explosive compound possible, for there does not exist another compound which contains at the same time a larger quantity of O and a superior endothermic capacity. However, 1 kg. of a stoichiometric mixture of liquid H and liquid  $\text{O}_3$ , if it could exist, would develop 4500 Cal. But this does not mark the limit of our resources, for the energy change attendant on the disintegration of Ra surpasses the latter number 200,000 times. Chemistry may, by attaching the radioactive forces to elementary atoms, and by developing the electric arc under solar conditions of temperature and pressure, produce explosives of a fabulous character.

CHARLES E. MUNROE.

**Military explosives of to-day.** J. YOUNG. *J. Roy. Soc. Arts* 66, 706-15, 719-30, 733-42 (1918).—A popular exposition of methods of manufacture and of characteristics with descriptions of simple illustrative experiments. There have been no epoch-making discoveries in explosives such as, say, the discovery of nitroglycerin, for many years. None is likely to be made until someone discovers how to dissociate elements into their primitive constituents in the fraction of a second, in the same way that radium is dissociated in a million years or so.

CHARLES E. MUNROE.

**Purification of marine fiber by nitration.** B. J. SMART. *Chem. Eng. Min. Review, Australia* 10, 380 (1918).—Posidonia or marine fiber is obtained from Spencer's Gulf, S. Australia. It contains 16.1% mineral matter, of which over  $\frac{1}{4}$  can be removed by mechanical means. By boiling this shaken material with 3%  $\text{H}_2\text{SO}_4$  solution for 3 hrs. and washing, the ash content was reduced to 0.68%. On treating this last material, after thorough drying, with 3 pts.  $\text{H}_2\text{SO}_4$  (1.84) and 1 pt.  $\text{HNO}_3$  (1.5) a yield of 72% of a product containing 12.3% of N and no ash was obtained. It was not possible to obtain a heat test higher than  $170^\circ\text{F}$ . for 10.5 minutes, probably because of the degree of comminution which, as Robertson and Smart have shown, affects the Abel test. But by the Will  $135^\circ$  test 2.5 g. of the product gave 6.4 mg. of N per 4 hours, while Waltham Abbey gun cotton gives 6.0-6.5 mg. in the same period; it is believed that this fiber shows promise as a source of gun cotton.

CHARLES E. MUNROE.

**Nitration of posidonia fiber.** B. J. SMART AND P. PRECOVER. *J. Soc. Chem. Ind.* 37, 300-11 (1918).—This is an amplification of the paper of the preceding abstract.

CHARLES E. MUNROE.

**Detection of acidity in smokeless powder.** A. ANGELI. *Atti accad. Lincei* 27, I, 164-6 (1918); *J. Soc. Chem. Ind.* 37, 608A.—All the known methods of detecting the stability of smokeless powder exhibit disadvantages. A. proposes to replace them by the use of the indicator dimethylaminoazobenzene. This forms red salts, which become fixed to the surface of the explosive as a dyestuff does to a fiber. A few cc. of distilled water containing 3 or 4 drops of a 0.2% alcoholic solution of the indicator are poured on to about 0.5 g. of the powder, the whole being well stirred. Powder of good quality turns lemon-yellow, whereas, if more or less acidity is present, it becomes more or less intensely red; in either case, the supernatant liquid remains completely colorless. Not all

explosives which are acid show low stability when subjected to the heat test, but expt. demonstrates that they inflame far more readily than normal explosives when kept in large amt. at a relatively high temp., and they also burn irregularly and incompletely, and in the firing test exhibit abnormalities in the pressure and range. A dil. soln. of the above indicator may be used for revealing the effect of light on smokeless powder; the parts of the latter which have been exposed are turned red by the soln., whereas the other parts become yellow.

CHARLES E. MUNROE.

**Color reaction of mercury fulminate with phenylhydrazine.** A. LANGHANS. *Z. angew. Chem.* 31, I, 161-3(1918); *J. Soc. Chem. Ind.* 37, 637A.—When dry mercury fulminate, 0.2 to 0.3 g., is treated with 0.5 to 1 cc. of phenylhydrazine and allowed to stand, the powder becomes olive-green changing to gray, while the liquid becomes brown and then reddish brown. When dild., after a few hours, with  $C_2H_5OH$  and treated with dil.  $H_2SO_4$ , the liquid gives a fine reddish violet coloration. The reaction, which is very sensitive, takes place more rapidly on heating. It can be used for the detection of  $Hg(NOC)_2$  in the presence of  $KClO_3$ ,  $Sb_2S_3$ , glass, and adhesive substance as contained in detonator and percussion cap compns. The reaction is also produced by  $HCl$  or  $HNO_3$  though not so sharply. Alkalies change the color to yellow and give a ppt., while acids restore the original color. A soln. of  $Hg(NOC)_2$  in  $Na_2S_2O_3$  or in  $C_6H_4N$  also gives the reaction. If, prior to the reaction, the phenylhydrazine is treated with  $CH_3I$  an intense violet to bluish violet coloration of the character of methyl violet is obtained. The dyestuff can be extd. with  $CHCl_3$ ; its reactions indicate that it is parosaniline.

CHARLES E. MUNROE.

**New detonators made without fulminate of mercury.** ANON. *Prof. Notes U. S. N. Inst. Proc.* 44, 2625(1918).—The Germans produced a cap by inserting in the brass or copper capsule a strip of tin, the exposed face of which was varnished with lacquer in which red P and a small amount of diphenylamine had been incorporated, and then pressing in 30 mg. of a mixture of equal parts of  $KClO_3$  and  $Sb_2S_3$ . When struck the friction of the red P against the charge produces ignition. The device is alleged to possess the proper degree of sensitiveness, great ignition capacity and perfect keeping qualities.

CHARLES E. MUNROE.

**Safety of TNT as an explosive.** J. M. WEISS. *J. Ind. Eng. Chem.* 10, 1028 (1918).—TNT as manufd. may contain highly nitrated phenolic derivs. which form unstable salts with metals and accidental explosions of TNT may have been due to this cause. W. gives a citation from Nolting and Forels' investigation of the 6 isomeric xyliidenes (*Ber.* 18, 2668) in confirmation of his views.

Indigo industry in Swatow district. ANON. *J. Roy. Soc. Arts* 67, 21(1918). E. J. C.

The absorption of sulfuric acid by wool with some notes on the theory of dyeing. W. HARRISON. *J. Soc. Dyers Colourists* 34, 57-8(1918).—The author and others observed (*Trans. Faraday Soc.*, Apr., 1910) that the positive elec. charge acquired by wool after boiling with dil.  $H_2SO_4$  soln. changed to negative when boiling water was passed through the wool, showing that the acid had been removed. The acid function of wool (corresponding to a negative charge) appears therefore to be predominant. Lloyd (*C. A.* 7, 4074) pointed out that after wool was boiled in acid the acid absorbed was partly removed by boiling water although a considerable portion was retained. Fort and Lloyd (*C. A.* 8, 3370) came to the conclusion that some acid was permanently retained after repeated extns. In order to ascertain whether or not the conclusion arrived at by Gee and the author was correct a series of expts. has been made. Five g. of wool were boiled in 300 cc. of water containing  $H_2SO_4$  (4.9% on the wt. of wool) for 1 hr. After cooling, the wool was well rinsed and packed lightly in a glass tube. The acid unabsorbed was titrated and the wool extd. with boiling water. 24 extns. were made, each being titrated separately. The results are recorded as a curve. In the expts. of Fort and Lloyd 2% of acid remained after 12 extns., whereas in the present expt. only 1% remained after 4 extns., 0.2% after 14; after 24 extns. practically all the acid was removed and the wool had no more affinity for acid colors than untreated wool. In accordance with the known facts relating to phenomena of this kind there should be conditions of concn. and temp. where the amt. of  $H_2SO_4$  passing into soln. should bear a mol. relationship with the amt. of dyestuff or other salt absorbed, and H. cites an instance of a ppt. being formed when starch is treated with  $Ba(OH)_2$ . The author concludes that the dyeing of wool with acid dyestuffs is a colloid-chem. problem and not an ordinary chem. reaction. L. A. OLNEY.

The theory of the acid dye bath for wool. M. FORT. *J. Soc. Dyers Colourists* 34, 124-6.—Harrison (cf. preceding abstract) describes a method by which  $H_2SO_4$  may be completely removed from wool with which it has been boiled. This is contrary to

the findings of previous investigators. F. regrets that there was no definite assurance as to the purity of the water used for extn. The amt. of acid remaining would only be equal to 1.5 parts in 100,000, based upon the quantity of water used by H. in his extn., hence the necessity for assurance of complete absence of temporary hardness and alkalinity. It is usual in the titration of water exts. of wool to find the presence of albuminoid matter which may cause an opalescence as neutrality is approached and slightly affects the figures in the direction of over-titration. F. believes that a large amt. of evidence relating to the equil. in dyeing and stripping and the chem. properties of fiber and dye must be dealt with before the chemical theory of dyeing wool in an acid bath can be abandoned in favor of a theory based upon remote causes of attraction in other fields. The present elec. theory of dyeing appears to include within its scope both contact-elec. phenomena and electrochem. ionic transferences without sufficient differentiation. The comparison made by H. between the combination of  $\text{H}_2\text{SO}_4$  with wool and colloidal pptn. of starch by  $\text{Ba}(\text{OH})_2$  does not enable one to understand how wool is able to affect the decompn. of  $(\text{NH}_4)_2\text{SO}_4$  and that wool can be dyed with acid dyes in a dye bath containing  $(\text{NH}_4)_2\text{SO}_4$  without the dye bath necessarily becoming acid throughout the whole operations. F. points out other conclusions of H. which he believes difficult to reconcile with previous results and believes that the adoption of the elec. theory in regard to the acid dye bath at present would obscure more than it can reveal.

L. A. OLNEY.

**The theory of the acid dye bath for wool.** W. HARRISON. *J. Soc. Dyers Colourists* 34, 127-8(1918).—Communication in reply to M. Fort's criticism (cf. preceding abstract) of H.'s paper (cf. second abstract above) states that all obvious precautions were taken to avoid error. Had the water been alk. the results by titration would obviously have been lower and would have indicated less acid removed. Various authorities are mentioned in support of H.'s views and in conclusion he states that the elec. theory is in no way opposed to the chem. theory.

L. A. OLNEY.

**Discussion on the theory of dyeing.** W. HARRISON, *et al.* *J. Soc. Dyers Colourists* 34, 96-9(1918).—The chem. theory of dyeing assumes that wool and silk form a chem. compd. together with the dyestuff. In the case of basic dyes the basic portion enters directly into combination with the fiber while the acid portion is left in the bath. In the case of acid dyes Knecht found that dyestuffs of the same homologous series were absorbed by wool in proportion to their mol. wts., but this did not hold for dyestuffs of different series. More recently Fort (*C. A.* 9, 2711) showed that under certain definite conditions the amt. of  $\text{H}_2\text{SO}_4$  left free in the bath over and above that left when no dye was used corresponded in wt. to the amt. of dye absorbed. He also found (*C. A.* 9, 2710) this relationship did not hold during other conditions of concentration. H. has recently pointed out (*Ibid* 34, 5) that these exceptions are met with in several cases of adsorption. The mechanical theory was based on the fact that substances of an indifferent nature such as glass beads, porcelain and quartz, could be dyed in a similar manner to fibers only to a less extent. Georgievics held that most cases of dyeing were in agreement with Henry's law in regard to the distribution of a substance between two solvents. The surface tension or adsorption theory is a modification of the mechanical calcns. of Gibbs, who showed that substances which diminish the surface tension of water at the surface of contact with air or with another liquid become concd. at that surface. In the elec. theory 4 factors are taken into account: (1) the mol. movement of dyestuffs in soln. which gives rise to osmotic pressure phenomena, rise in b. p., lowering of the f. p., Brownian motion, etc.; (2) the elec. charge on the dye and on the fiber; (3) the surface of the fiber including that within its pores; and (4) the size of the dye particles. The mol. movement of dye particles or ions enables them to get into contact with the fiber, the movement being accelerated or retarded as the elec. charges

upon the dye and fibers are of the opposite or same sign, resp. The dye particles or ions may be held on the fiber by elec. attraction when dye and fiber carry opposite charges, or by other means when the charges are of the same sign, as is the case with direct colors on cotton. In this case the dye is coagulated on or in the fiber, because its elec. charge is neutralized by the oppositely charged ions of water mols. immediately in contact with the fiber.

L. A. OLNEY.

**Theories of dyeing.** J. I. CRAVEN. *J. Soc. Dyers Colourists* 34, 128(1918).—Over 50 years ago Crum proposed the following theory which has not been improved upon to any extent: Dyes whether substantive or adjective do not combine chemically with the fiber but are imbibed into cavities and pores by what is termed capillary attraction which has the power of decomposing certain substances and retaining them within cells or cavities.

L. A. OLNEY.

**Properties of airplane fabrics.** E. DEAN WALEN. Washington. *J. Am. Soc. Mech. Eng.* 40, 933-7(1918).—A subtitle reads "Methods used by the Bureau of Standards in developing a cotton fabric as a substitute for linen for airplane wing coverings." Previous difficulties encountered in expts. on cotton fabrics were four: low strength per unit wt.; low tearing resistance; little shrinkage upon the application of dope; little tendency to retain that slight shrinkage after doping. The method of covering airplane wings is described, also the methods for detg. the properties of undoped fabrics. The points detd. were moisture, wt., length of yarn, crimp, yarn count, thread count, twist of the yarns, tensibility properties, tearing resistance, resistance to uniformly distributed pressure, and bursting-tear. Several special pieces of app. for making some of the above tests are described with illustrations. Similar tests were made on doped fabrics. Dope films were made by painting the dope on glass plates and the films were subsequently peeled off and tested for tensile strength and resistance to pressure. The results of the tests are shown in five diagrams of curves with full descriptions. When properly made, a cotton fabric is capable of resisting more pressure than linen and will have practically the same tautness. The maintenance of the strength and tautness of cotton fabrics is dependent upon the completeness with the dope protects the fabric and the completeness with which the dope is protected from deteriorating influences such as light and weather. Further expts. are being conducted.

L. W. RIGGS.

**English methods for finishing sateens.** A. FIELD. *Dyer, Calico Printer; Color Trade J.* 3, 395-9(1918).—Minute details are given of the practice as followed in English factories. Twelve formulas are quoted giving the compn. of finishing mixts. to produce various results in the appearance of the fabric.

L. W. RIGGS.

**Sections of artificial silk.** H. DE CHARDONNET. *Compt. rend.* 167, 489-91(1918).—The transverse section of a thread of raw silk shows a crescent form on account of the gum covering the two filaments which make the thread. Each of these filaments in cross section presents the form of a triangle with the angles rounded. Artificial silk is made by projecting a liquid into water or into air, where it instantly coagulates and is followed in the latter case by the evapn. of the solvent. The projection into air furnishes fibers of greater solidity and transparency. Silk made by pptn. in water is usually circular in cross section which upon evapn. of the solvent becomes deeply scalloped, while that made in air gives a cross section more or less elongated with rounded ends. The nature of the fibers is modified by the concn. of the pyroxyline in the alc. ether solvent.

L. W. RIGGS.

**Corn starch in the textile industry.** W. R. CATHCART. *Text. Colorist* 40, 339-42(1918).—This paper is largely a criticism of statements made by C. C. Moore in a pamphlet entitled "The use of starch in the textile industry, with special reference to the value of potato starch for sizing and finishing." The principal advantages claimed

for Corn starch are low cost and uniformity of action under the conditions of its use in textile industries. It changes its viscosity but slightly on boiling while potato starch loses more than two-thirds of its viscosity by boiling 30 min. (cf. MacNider, *C. A.* 7, 550, 1421). Since corn starch is manufactured continuously throughout the year in large factories under scientific supervision, a product having any property desired by the textile manufacturers may be uniformly produced. L. W. RIGGS.

The possibility of cultivating fiber plants in Australia. T. HOGG. Commonwealth of Australia, Advisory Council of Science and Industry, *Bull.* 7, 126-34 (1918). E. J. C.

A new bleaching powder for use in hot climates (RETTIE, *et al.*) 18.

Dyes. SOC. CHIMIQUE DES USINES DU RHONE, ANCIENNEMENT GILLIARD, P. MONNET ET CARTIER. *Brit.* 119,860, Aug. 21, 1918. Bromoindigos and homologs thereof are obtained by brominating indigo or its homologs or their lower halogen derivs. in chlorosulfonic acid in the presence of a dehydrating agent having greater affinity for  $H_2O$  than has  $SO_3$ ;  $P_2O_5$  is specified. Examples are given for the production of tetrabromoindigo and tri-, tetra-, penta-, and hexabromo-*o*-tolyindigo.

Vat dye from 1-aminoanthraquinone-2-aldehyde and hydrazine. G. KALISCHER. U. S. 1,285,727, Nov. 26. A monoazo dye is obtained by condensing an azomethine compd. derived from 1-aminoanthraquinone-2-aldehyde (or the latter compd. itself) with hydrazine. The dye is a dark red powder, very difficultly sol. in org. solvents of high b. p., sol. in concd.  $H_2SO_4$  with an olive color which on the addition of paraformaldehyde is changed into an intense greenish blue color and yields a blackish violet vat with hyposulfite and NaOH, which dyes cotton claret-red shades of good fastness.

1-Aminoanthraquinone-2-aldehyde. G. KALISCHER. U. S. 1,285,726, Nov. 26. 1-Aminoanthraquinone-2-aldehyde, crystals with a metallic luster, m. about  $233^\circ$ , dissolving in concd.  $H_2SO_4$  with a brown color which on addition of paraformaldehyde is changed to blue, and yielding with hyposulfite and NaOH a bright green vat, is made by treating with acids the condensation products formed by heating 1-amino-2-methylantraquinone with aromatic nitro compds. such as  $PhNO_2$ , with the addition of  $PhNH_2$  or other primary aromatic amine and in the presence of alkalies.

Wool-like pattern effects on cotton. O. KLAUSER. U. S. 1,285,738, Nov. 26. Wool-like pattern effects on cotton are produced by printing with a resist and treating the fabric, thus prepd., with  $H_2SO_4$  of a strength of less than  $50.5^\circ$  Bé. at a temp. of about  $-4^\circ$  or lower and then washing out the acid and resist. Cf. *C. A.* 12, 1422.

Dyeing. V. PLANTÈ. *Brit.* 119,881, Aug. 17, 1917. Piece goods or garments of wool, silk, or velvet, are dyed by means of basic dyes dissolved in  $CCl_4$  (with or without alc.) with the aid of a mordant containing  $NH_4$  gallate and oleate, prepd. from a mixt. in specified proportions of triolein gallic acid, alc., and aq.  $NH_3$ . The process is assisted by passing an elec. current through the dye bath; for this purpose the goods are placed in an Fe wire basket immersed in dye liquid in an Fe vat provided with leads. After being dyed the materials are extd. with benzine and rinsed.

## 26. PAINTS, VARNISHES AND RESINS.

A. H. SABIN.

Polymerization of linseed-oil and wood-oil. W. FAHRION. *Chem. Umschau* *Pette, Oele, Wachse u. Harze* 24, 102-4, 117, 144-5 (1917); 25, 14-5, 27-8, 39-40, 51-2, 63-4, 74-7, 87-8 (1918).—A critical review. TH. VERHEGGEN.

Thymolphthalein as an indicator in the acidimetry and alkalimetry of dark solutions (HOLDE) 7.

**Pigments.** E. F. MORRIS and T. N. C. NEVILL. Brit. 119,713, Oct. 17, 1917. A white pigment consisting of a mixt. of Sb oxide and  $\text{BaSO}_4$  is produced by treating  $\text{Sb}_2(\text{SO}_4)_3$ , or the product obtained by treating  $\text{Sb}_2\text{O}_3$  with  $\text{H}_2\text{SO}_4$  with  $\text{BaCO}_3$ .

**Antimony oxide.** E. F. MORRIS and T. N. C. NEVILL. Brit. 119,711, Oct. 17, 1917. Sb oxide for use as a pigment is rendered free from acid substances by heating it in  $\text{H}_2\text{O}$  with a substance which neutralizes acids, such as  $\text{Na}_2\text{CO}_3$ , borax, pptd. chalk, or a mixt. of these. As an example, a thin mixt. of Sb oxide and  $\text{H}_2\text{O}$  is treated with milk of lime and  $\text{H}_3\text{BO}_3$  in such proportions as to leave the resulting soln. alk. to litmus but not sufficiently alk. to give a ppt. of chalk on breathing into it. The quantity of lime required is about 0.5% of the quantity of Sb oxide.

**Antimony oxide.** E. F. MORRIS and T. N. C. NEVILL. Brit. 119,712, Oct. 17, 1917. Sb oxide for use as a pigment is purified from compds. of an acid nature by treating it, preferably while suspended in air in a comparatively dry state, with a substance which neutralizes acid.  $\text{NH}_3$ , an org. amine, or an atomized alk. substance such as Ca borate may be employed.

**Paint for wood.** T. SUZUKI. Jap. 31,422, Aug. 22, 1917. A wood paint is prepd. by mixing alizarin black, red, and violet,  $\text{K}_2\text{Cr}_2\text{O}_7$ , glacial  $\text{HOAc}$ , and gum arabic. E. g., alizarin black 2.34, alizarin violet 1.75, alizarin red 0.59,  $\text{K}_2\text{Cr}_2\text{O}_7$  15.99, glacial  $\text{HOAc}$  20.00, and gum arabic 14.00.

## 27. FATS, FATTY OILS AND SOAPS.

E. SCHERUBEL.

Report of the committee on the analysis of commercial fats and oils. W. D. RICHARDSON, *et al.* *J. Ind. Eng. Chem.* 11, 69-71 (1919).—The committee's rept. is accompanied by "Corrections to tentative standard methods for the sampling and analysis of commercial fats and oils to Sept. 4, 1918," and by a statement, with notes, of the "Methods of analysis adopted September 4, 1918." E. J. C.

The occurrence of azelaic acid as a product of the spontaneous oxidation of fats. BEN H. NICOLET and LEONARD M. LIDDLE. *J. Ind. Eng. Chem.* 8, 416-7 (1916).—This paper has been previously overlooked through an error. E. J. C.

The treatment of oats to obtain oil. HUGO DUBOVITZ. *Chem. Ztg.* 42, 13-4 (1918).—3250 kg. of shelled oats, with an oil content of 7.17%, were extd. There were obtained 129 kg. of 96.32% oil and 343 kg. emulsion (with an oil content of 14.3%). After the treatment the oats still contained 1.54% of oil. The oil after purification with  $\text{H}_2\text{SO}_4$ , had the following compn.: water 3.68%, ash 0.08%, unsaponifiable matter 1.61%, acid value 62.11, sapon. value 180.13, iodine value 91.73,  $n_{\text{D}}^{20}$  1.4706, glycerol content 7.50%,  $d_{4}^{20}$  0.9110. TH. VERHEGGEN.

Soap industry in Argentina. JOSÉ M. FERREIRO. *Anales soc. quim. Argentina* 6, 52-6 (1918).—F. gives typical analyses of the following 4 classes of soaps mfd. in Argentina: (1) yellow, (2) perfumed, (3) medicinal, (4) antiseptic. The content of fatty acids in these 4 classes showed the following resp. variations: (1) 17.97-36.35%, (2) 53.36-78.91%, (3) 60.30-74.30%, (4) 1.30-21.22%. The resp. contents of resins varied as follows: (1) 17.49-25.87%, (2) 10.12-11.09%, (4) 3.42-16.70%. The common yellow soaps were largely adulterated with inorganic material, the av. content being 19.7% (principally  $\text{CaCO}_3$  and  $\text{Na}_2\text{CO}_3$ ). The contents of  $\text{H}_3\text{BO}_3$ ,  $\text{Na}_2\text{B}_4\text{O}_7$ , glycerol and  $\text{HgCl}_2$  present in various samples of medicinal soaps were detd. The tech-

nic of the soap industry in Argentina has not been highly developed; complete sapon. of fats is only practised in the case of the finest soaps. F. suggests the following measures for improving the status of the industry: (1) installation of factories for "splitting" fats with production of products such as glycerol, stearin, etc.; (2) stimulation of the culture of oil-producing plants which are of value to the industry; (3) establishment of an electrolytic NaOH industry; (4) passage of laws and adoption of regulations for controlling the quality of common soaps; (5) establishment of adequate chem. control in the factories to guarantee the quality of the raw material employed and the efficiency of the technic of manuf.

H. S. PAINE.

**Hydrogenating fatty substances.** C. ELLIS. U. S. 1,285,959, Nov. 26. The material to be hydrogenated, *e. g.*, crude oleic acid, is mixed with colloidal Ni or other catalyst and atomized in a current of H, hydrogenated product is sepd. and unhydrogenated material is returned to the hydrogenating app. for a repetition of the treatment. U. S. 1,285,960, specifies the use in hydrogenation, of colloidal catalytic material such as Ni, Co, Cu or Fe, together with H, which is free from O and Cl. Exclusion of the latter substances avoids deterioration of the catalyst.

**Soap mixture.** J. W. BODMAN. U. S. 1,285,004, Nov. 19. A mixt. of thick, pasty consistency is formed of soap mixed with H<sub>2</sub>O and with about 30% its weight of alc. and about 3 times as much of a hydrocarbon solvent such as naphtha, some of the latter being liberated upon the addition of H<sub>2</sub>O to the mixt. at the time of use. The mixt. is especially adapted for removing grease and oil. CCl<sub>4</sub> may be used instead of naphtha.

**Washing compound.** A. IMHAUSEN. Dan. 23,346, Aug. 5, 1918. A washing compd. is composed of soap, benzine or benzene, and an oxidizing agent such as NaBO<sub>2</sub>, with NH<sub>4</sub>Cl to prevent explosion. Cf. C. A. 12, 1602.

## 28. SUGAR, STARCH AND GUMS.

A. HUGH BRYAN.

**Beet sugar industry in the United States.** C. O. TOWNSEND. U. S. Dept. Agr., *Bull.* 721, pp. 56(1918).—A list of beet-sugar mills of the U. S. is given showing their location and capacity, together with a discussion of the factors influencing the growth, cultivation, harvesting, etc., of sugar beets.

J. J. SKINNER.

**The Australian sugar industry.** HARRY T. EASTERBY. Commonwealth of Australia, Advisory Council of Science and Industry, *Bull.* 7, 135-52(1918). E. J. C.

BLAKE, A. F.: *Nomon*. Sugar Technologists' Edition. Urbana, Ill.: The Nomon Sales Agency. \$1.50. For review see *J. Ind. Chem. Eng.* 11, 86(1918).

CHAUDHURI, TARINI C.: *Modern Chemistry and Chemical Industry of Starch and Cellulose*. Calcutta: Butterworth & Co. 156 pp. 3-12.

**Apparatus for extracting sugar juices from plant materials.** L. NAUDET. U. S. 1,286,066, Nov. 26.

## 29. LEATHER AND GLUE.

ALLEN ROGERS.

**Theories of the different modes of tannage.** LOUIS MEUNIER. *Chimie & industrie* 1, 71-80, 272-6(1918).—See C. A. 12, 2706.

E. J. C.

**Log bark.** ANON. *J. Am. Leather Chem. Assoc.* 13, 595-6(1918).—The Forest Products Lab., U. S. Dept. of Agr., has completed expts. on a com. scale which indicate that hemlock bark, free from wood, obtained in paper mill operations, can be successfully used as a source of tannin. E. J. C.

**Ceanothus velutinus (snow brush) as a source of wax and tannin.** CHAS. C. SCALIONE AND HERBERT S. BLAKEMORE. *J. Ind. Eng. Chem.* 8, 411-3(1916).—This paper has been previously overlooked through an error. E. J. C.

**Extracting glue from chrome-tanned leather.** F. J. TURNER. U. S. 1,285,474, Nov. 19. Chrome-tanned leather or leather scrap (after soaking) is placed in a soln. containing 0.75 oz. NaOH for each lb. of leather used and boiled to ext. the glue, and the soln. is sepd. and evapd. to the desired viscosity.

**Tanning hides.** K. HARING. U. S. 1,285,144, Nov. 19. Hides are dehydrated by treatment with alc. or other suitable liquid having an affinity for H<sub>2</sub>O, subjected to reduced pressure and then treated with asphaltum and subjected to super-atmospheric pressure.

### 30. RUBBER AND ALLIED SUBSTANCES.

JOHN B. TUTTLE.

**Venezuelan production of balata.** ANON. *J. Roy. Soc. Arts* 67, 46-7(1918). E. J. C.

DITMAR, R.: **Mischungsbuch für die Kautschuk-, Guttapercha-, Balata-, Kabel-, Isolier- und Factis-industrie.** Wien und Leipzig: W. Braumüller. 170 pp. f. 2.10.

**Apparatus for testing the expansion of rubber and other plastic materials.** W. JAMESON. U. S. 1,282,085, Oct. 22.

**Colored vulcanized rubber compositions.** J. M. WEISS. U. S. 1,282,505, Oct. 22. Vulcanized compns. of light color are formed by incorporating with the rubber mixt., prior to vulcanization, a light-colored semi-solid or solid bitumen such as may be obtained by the destructive distn. of coal-tar pitch, and then subjecting the mixt. to vulcanization.

**Composition for soles of foot-wear.** G. R. WYMAN and A. E. CURRIER. U. S. 1,284,023, Nov. 5. A compn. for shoe-soles or heels is formed of a mixt. of comminuted waste felt roofing, satd. and treated with asphaltum and boiled linseed oil, reclaimed rubber, PbO, S and ZnO, all vulcanized together.

**Mixing rubber with pulverulent materials.** W. C. KNOWLTON and H. A. HOFFMAN. U. S. 1,286,024, Nov. 26. Pulverulent substances such as lampblack, to be compounded with rubber, are formed into granular lumps with a binder such as starch paste and these lumps are then incorporated in dry condition with rubber on a heated mixing mill. The formation of the pulverulent material into lumps, as a preliminary step, serves to prevent spreading of dust in the atm. during the mixing.

**Reworking rubber from old tires.** F. L. HARLEY. U. S. 1,285,992, Nov. 26. The method relates chiefly to comminution and other mechanical treatment of the material.

**Impregnating or coating textile fabrics with balata.** L. A. FRANCOIS. U. S. 1,285,105, Nov. 19. A soft, pasty mass of balata is passed between heated rolls and then applied to fabric to be coated, on both sides of the fabric simultaneously, and the

coated fabric is then successively passed between calendering rolls and around a cooled and moistened roll.

**Rubber substitute.** E. R. TALLEY. U. S. 1,285,463, Nov. 19. A mixt. for use as a rubber substitute is formed of vegetable oils, coal tar or asphalt, camphor, powdered shale and S, vulcanized together. Asbestos and white lead also may be used.

**Substitutes for rubber, etc.** F. J. BENNETT and F. W. MELLOWES. Brit. 119,878, Oct. 10, 1917. Substitutes for rubber, vulcanite, etc., are made by mixing together a fatty oil, S, or compd. of S, and stearin, or other hard fat, with or without other ingredients and then heating them. In some cases, the heating is performed in a vessel capable of resisting heat and pressure. The fatty oils employed may be linseed oil or castor oil; they may be replaced in part (from 5 to 40%) by a mineral oil such as petroleum oil. In one example, the following ingredient and proportions are employed: linseed oil 1, S 1, stearin 1,  $\text{Fe}_2\text{O}_3$  0.5. A small proportion of tar, or resin or other pitch-like substances may be added. Also lime may be added. The material may be strengthened by adding sawdust, cellulose in the form of cotton, jute, and paper. The material is sol. in most of the well known rubber solvents and then forms a varnish.

**Rubber.** GENERAL RUBBER CO. Brit. 116,324, June 1, 1917. A process of drying coagulated or uncoagulated latex comprizes insolubilizing the nitrogenous matter and then submitting the mass to vacuum evapn. The insolubilization may be accomplished by the action of heat or by the action of agents such as antiseptics, polycyclic org. compds., hydroxynaphthalenes (particularly  $\beta$ -naphthol), and enzymes. Suitable app. is specified.

**Rubber.** GENERAL RUBBER CO. Brit. 116,326, June 1, 1917. Rubber latex is treated with a polycarbocyclic member of the benzene series or with a hydroxy deriv. thereof in order to conserve therein the nitrogenous and other constituents of the latex and to prevent the formation of slime. *E. g.*, the latex may be treated with 0.2% of  $\beta$ -naphthol before or after the addition of S, and the product may in addition be given a surface treatment with an alc. soln. of  $\beta$ -naphthol.

**Rubber, etc.** GENERAL RUBBER CO. Brit. 116,323, June 1, 1917. Coagulated rubber, gutta, chicle, and like latex is treated, *e. g.*, with mono- or polyhydroxymono- or polycyclic benzenoids or their ethers, esters, salts, polymers, or other compds. of them, such as gallic acid, tannins, cresols, naphthols, diaminophenol, *p*-aminophenol,  $\beta$ -naphthol, etc., in order to form in the coagulum an insol. layer which prevents the passage therethrough of colloidal nitrogenous matter, etc., and so prevents the formation of slime on the coagulum. *E. g.*, freshly coagulated rubber is immersed in a 5% soln. of  $\beta$ -naphthol in alc. for 30-40 seconds and then allowed to dry, the membrane which is formed being permeable to  $\text{H}_2\text{O}$ . The reagent may also be dusted, sprayed, or painted on, or applied as a paste. S or other vulcanizing agent may be incorporated prior or subsequent to the treatment.

**Rubber, etc.** GENERAL RUBBER CO. Brit. 116,322, June 1, 1917. Unvulcanized rubber or similar vulcanizable material is subjected to the action of a vacuum for removal of the fluids normally contained within such materials, the vacuum being subsequently broken by the introduction of an inert gas or liquid. Examples of suitable inert substances are  $\text{CO}_2$ ,  $\text{NH}_3$ , H, and N. Cf. 10,695, 1913 (*C. A.* 8, 3507), and 17,193, 1914 (*C. A.* 10, 296).

**Plastic compositions.** NAAMLOOZE VENNOOTSCHAP NEDERLANDSCHE-MAATSCHAPPIJ TOT EXPLOITATIE VAN OPTIMIET FABRIEKEN. Brit. 118,270, June 13, 1918. In the manuf. of substitutes for ebonite derived from rubber and for the phenol-formaldehyde condensation products, waste or new rubber is dissolved in a drying oil (or an oil, such as rapeseed oil, which can be vulcanized) with which have been mixed by

heat, paraffin, wax, stearin, or similar substance and also resin or resinous material. The pulp thus made is intimately incorporated with finely divided filling material in quantity to yield a thin film of the oil on each particle of filler. S or other vulcanizing material is mixed with the filler. Suitable fillers are chalk, barytes, infusorial earth, and clay. The plastic mass is pressed or molded and vulcanized by steam.

**Vulcanizing rubber.** C. E. ANDREWS. U. S. 1,280,940, Oct. 8. Aminocymene or one of its salts is used in vulcanizing rubber with S, to shorten the time required for vulcanization. The proportion of aminocymene added may be 0.5-5%.

**Vulcanizing rubber, etc.** MORGAN & WRIGHT. Brit. 118,305, Aug. 9, 1917. The extent of expansion during vulcanization is taken as indicative of the degree of vulcanization attained. The invention consists in heating the rubber, etc., previously mixed with a vulcanizing agent, and discontinuing the supply of heat when the rubber has expanded to an extent indicative of the degree of vulcanization desired. A series of expansions during the time of application of heat may be detd. with a sample of rubber compd. confined in a cylinder provided with a piston and gage for indicating expansion and with a steam jacket. A table prepd. from these observations can be used as a guide in mfg. vulcanized articles.

# CHEMICAL ABSTRACTS

Vol. 13.

FEBRUARY 20, 1919.

No. 4

## I. APPARATUS.

L. C. JONES.

**Gas bubbler for gas analysis.** O. D. BURKE. *Chem. News* 117, 368-9(1918).—A narrow, glass tube is drawn out at one end into a very fine capillary, which is ground level at the point or end. Another glass tube is fused on to the straight tube (as a side tube), and extends downwards to just beneath the capillary, where it is flattened out and the top surface ground. The capillary is made to fit tightly on the flat ground surface of the second tube. The upper end of the straight tube passes through a 2-hole stopper which is inserted in a bottle or flask containing the absorbent, and connected to an aspirator. Gas passing through the capillary tube is broken up into very fine bubbles, no rushing can take place, and the time interval for the passage of a certain vol. of gas is identical in all cases. F. W. SMITHER.

**The determination of the specific gravity of liquids.** K. NORTON. *Gas World* 69, 284(1918).—The author recommends the use of a plummet, giving instructions for making same in the lab., and describing its calibration and use. F. W. SMITHER.

**Automatic variation of gas pressure and its application to a vacuum pump, circulation of gases, magnetic stirrer.** O. MAASS. *J. Am. Chem. Soc.* 41, 53-9(1919).—A control is described for making a Töpler mercury pump automatic. Description is given of an app. which enables a definite quantity of gas to be withdrawn from or circulated through the same app. A magnetic stirrer is described. ERLE M. BILLINGS.

**An instrument for recording sea-water salinity.** A. L. THURAS. *J. Wash. Acad. Sci.* 8, 676-87(1918).—The instrument previously described (cf. *C. A.* 12, 1353, 1714, 1846) has been tested and exptl. data have been obtained. The app. and method are described in detail with illustrations. The various sources of error have been investigated; they were mostly found to be negligible. The accuracy of the method is limited by the accuracy with which the standard sea-water in the sealed cell is known. The sp. cond. at 25° of sea-water throughout the range of concn. found in the open ocean was found to be 0.04518 to 0.05767 reciprocal ohms; salinity, 29.15 to 38.46;  $d_{20}$ , 1.01896 to 1.02598. The mean temp. coeff. of sea-water per degree between 18° and 25° expressed in terms of cond. at 18° is 0.02237 for a salinity of 29, and 0.02212 for a salinity of 37. The paper concludes with suggested applications of the salinity recorder in conjunction with other recent recorders for making physical oceanographic measurements. F. W. SMITHER.

**The plexsim electric still.** ANON. *Electrician* 81, 724(1918), 2 illus.—A brief description of a small elec. still intended primarily as a convenient means of providing distd. water in labs. C. G. F.

**Checking calibration of thermocouples and pyrometers.** ANON. *Elec. Rev.* 74, 56-9(1919).—A detailed illus. account of sources of error, methods of calibrating, maintenance of standards and app. required. C. G. F.

**Acetylene generator.** C. LAY. U. S. 1,286,665, Dec. 3.

## 2. GENERAL AND PHYSICAL CHEMISTRY.

WILLIAM D. HARKINS AND E. B. MILLARD.

**The methods of chemistry.** H. J. PRINS. *Chem. Weekblad* 15, 1381-8(1918).—A philosophical discussion. It is maintained that "facts" are as perishable as "theories," in that they are dependent on the accuracy and reliability of our observations. Future refinements in methods and instruments may change or revise the facts of today.

JULIAN F. SMITH.

**Technics and science.** G. DE CLERCQ. *Chem. Weekblad* 15, 1530-45(1918).

E. H.

**Filtration in the laboratory.** ROBERT T. SMITH. *Color Trade J.* 4, 21-4(1919).—Discussion of natural filtration without pressure, filtration by suction, and filtration under a hydraulic head, and of methods for washing ppts.

L. A. OLNEY.

**Scientific research in India.** ANON. *Engineering* 106, 606-8(1918).—A review and discussion based on: (1) Proceedings of a conference for the consideration of the organization of chem. research in India, held at Lahore, Jan. 8, 1918; (2) Indian Munitions Board handbook; (3) Annual Report of Indian Board of Scientific Advice, 1916-17.

F. W. SMITHER.

**The specific heat of platinum at high temperatures.** WALTER P. WHITE. Geophysical Lab., Washington. *Phys. Rev.* 12, 436-51(1918).—The specific heat of very pure, drawn, and carefully annealed Pt is given probably to within 2 per mille from 0° to 1300° by the formula  $0.03169 + 0.000064 \theta$ , in excellent agreement with what appears to be the best work of others, namely Magnus, 500-900°, and Gaede, to near 100°. The method was to drop a charge of about 160 g. from elec. furnaces into a water-filled calorimeter. From the results obtained it follows that the atomic heat at const. volume is 6.44 at 500°, 6.68 at 900°, 6.85 at 1300°.

W. P. WHITE.

**Specific heat of tungsten at incandescent temperatures.** PAUL FREDERICK GAHR. Cornell Univ. *Phys. Rev.* 12, 396-423(1918); cf. *C. A.* 12, 1432.—The sp. heat of a W filament is detd. from 1400 to 2600°. An elec. method is used, in which the elec. input, when the current is changed, equals the radiation plus the heat required to raise the temp. Unless special precautions are taken, the pyrometric detn. of instantaneous temps. is impracticable. The results when the temp. is rising are slightly different from those when it is falling. The exptl. difficulties are very great.

F. C. HOYT.

**Evaporation of small spheres.** IRVING LANGMUIR. *Phys. Rev.* 12, 368-70(1918).—Morse (*C. A.* 4, 1831) has detd. the rate of evapn. from small spheres of I in still air, and finds it proportional to the radius of the sphere and not to its surface. L. applies to this the theory already successfully applied to the convection of heat from small wires (*C. A.* 7, 1322). This assumes that the heat loss by "convection" consists essentially of conduction through a thin film of relatively stationary gas. The theory leads to the equation  $-dm/dt = 4\pi a D M p / RT$ , where  $m$  is the mass of the sphere,  $a$  the radius,  $D$  the diffusion coeff. for I,  $M$  the mol. wt.,  $T$  the temp. and  $R$  the gas const. The value of  $D$  calcd. from this equation and Morse's data is 0.053. No other data are available for this const., but the value seems reasonable compared to substances of similar mol. wt.

F. C. HOYT.

**Internal tension and complex molecules.** G. N. ANTONOFF. London. *Phil. Mag.* 36, 377-97(1918).—A theory of mol. attraction is based on the modern conceptions of atoms and mols. From this point of view the phenomena of mol. attraction depend on the same forces as chem. affinity. A relation between surface tension and mol. pressure has been mathematically deduced. Theoretically it is deduced that interfacial tension must be equal to the difference of the surface tensions against air of

both the superposed liquid layers, which agrees with expt. Two superposed layers in equilibrium are to be regarded as solns. in the same solvent; they must contain an equal number of mols. per unit vol. (Avogadro's law), as a result of the formation of complex mols. in the soln. The so-called monovariant systems may be obtained without fulfillment of the requirements of the phase rule if the mols. of the component added combine with those in soln. without increasing their number. S. C. LIND.

The spontaneous transformation to a colloidal state of solutions of odorous substances exposed to ultraviolet light. H. ZWAARDEMAKER AND F. HOGEWIND. *Proc. Acad. Sci. Amsterdam* 21, 131-7(1918).—Various solns. of odorous substances in water, glycerol, and paraffin were rapidly mixed and allowed to stand for several weeks. The following solns., arranged according to their degree of transformation, yielded a Tyndall effect: eugenol, cresol, guaiacol, citrol, cumidine, thymol and hyprion in water; eugenol, saffrol, creosote, nitrobenzene, cresol, and apiol in glycerol; and aniline, eugenol and cumidine in paraffin. Other solns. also gave a distinct effect. In general, the odorous substances which become intensely colloidal have a greater mol. wt. than those which are not transformed. The former generally bring about a lowering of the surface tension of water. On standing, the no. of submicrons appear to increase to the detriment of the amicrons. The surface tension and the odor of the solns. before and after transformation are approx. the same. The authors, therefore, term the transformed substances suspensoids. When exposed to an elec. current the particles appear to be negatively charged. When an aq. soln. of eugenol (1:1200) is heated beyond 40° the opalescence decreases and returns on cooling, becoming more intense after a few days. There is less opalescence on hot days than on cool days. The transformation process is more rapid in the sunlight than in the dark and still more rapid in ultraviolet light. Radium kept *in vitro* is effective in producing a colloidal state. The authors state that it is not likely that chemical energy comes into play but that there must be still another source of energy, as a eugenol soln. kept in a leaden casket becomes suspensoidal after a few days. F. POWDERMAKER.

The adsorption of arsenious acid by ferric hydroxide. M. C. BOSWELL AND J. V. DICKSON. *J. Am. Chem. Soc.* 40, 1793-1801(1918).—The curves of the adsorption of arsenious acid and of NaOH by Fe(OH)<sub>3</sub> in the presence of and absence of NaOH and of arsenious acid, respectively, have been constructed. The adsorption of arsenious acid is diminished by the presence of NaOH and the adsorption of NaOH is increased by the presence of arsenious acid. These measurements show a deviation from the simple adsorption equation  $E = \beta A^p$  where  $E$  is the concn. of the adsorbed material on the ppt.,  $A$  is the concn. of the adsorbed material in soln. and  $\beta$  and  $p$  are constants. If this simple equation held then the plot of the equation  $\log E = p \log A + B$  of all curves of a given adsorbent prepd. under varying conditions or of various ages would be a straight line with  $\beta$ , the intercept on the Y axis the only variable, and this would be Mecklenburg's "affine Adsorptionskurven." The logarithmic curves actually plotted show a concavity to the X axis. It would seem that the phenomenon of adsorption by gels from aqueous solns. has not the simplicity implied in the equation  $E = \beta A^p$ . What the theoretical significance of this deviation may be is not apparent. The exponent  $p$  remains const. for different preps. of Fe(OH)<sub>3</sub> where arsenious acid alone is used, but changes when alkali is present. H. I. MATTILL.

Colloidal silver. A. PICKLES. *Chem. News* 117, 358(1918).—On recovering Ag from residues the AgCl was converted to Ag<sub>2</sub>O in the usual way and thoroughly washed. To show its reducing power HCOH (60%) was used for the ultimate reduction, the operation being carried out in a vessel with a mech. stirrer. At 14° reduction was slow; at 35° reduction was accelerated, but the liquid acquired a pale lilac tint, increasing in intensity as reduction proceeded. This soln. passed unchanged through

ordinary filter papers, and has been preserved since June, 1917, the color becoming a rich ruby-red. No similar result could be obtained with acetaldehyde. Further expts. dispensing with continuous stirring and elevation of temp. gave no result in several cases, and in others only after several days, the color produced being only slight. The color was slowly discharged by salt solns.;  $\text{HNO}_3$  was most effective, especially on warming;  $\text{H}_2\text{O}_2$  (4 vol.) was slowly decomposed on slightly warming.

F. W. SMITHER.

**Inversion of cane sugar by colloidal silica.** ALBERT AND ALEXANDRE MARY. *Compt. rend.* 167, 644-6(1918).—Colloidal  $\text{SiO}_2$  was prepd. from  $\text{Na}_2\text{SiO}_3$  and  $\text{HCl}$ , and when dialyzed to 8% was very active in inverting cane sugar at temps. of 15 to 20°. Its catalytic power decreased after 5 to 6 hrs. The same hydrosol reduced to 5% by the addition of water retained its activity for 130 hrs. With a 1.5% hydrosol the activity was constant for four months. The duration of the period of activity is measured by the dispersive phase of the sols which are less stable as they are more concd. Non-dialyzed  $\text{SiO}_2$  hydrosols remain in a condition of physical instability comparable to that of cellular colloids, and rapidly coagulate. They slowly invert cane sugar and in general their action appears to be erratic. The addition of a slight excess of  $\text{Na}_2\text{SiO}_3$  to the non-dialyzed  $\text{SiO}_2$  gives a more stable product which also has a greater catalytic power.

L. W. RIGGS.

**Isomorphous mixtures.** PAUL GAUBERT. *Compt. rend.* 167, 491-4(1918).—Color phenomena are studied in mixts. of  $\text{KClO}_4$  and of  $\text{NH}_4\text{ClO}_4$  with  $\text{KMnO}_4$ , and in mixts. of chromates, sulfates and selenates of K, Cs, and Rb with  $\text{K}_2\text{MnO}_4$ . Optical indexes in relation to opacity of crystals were studied in mixts. of salts of Tl, Ag, and Pb with corresponding salts of K, Na, and Ba. Stability relations were observed in mixts. containing salts of Ag or  $\text{K}_2\text{MnO}_4$ . Crystals of chromates and selenates of K, Cs and Rb formed in a soln. containing  $\text{K}_2\text{MnO}_4$  are colored green, the intensity of color and therefore the amt. of manganate in the crystal being proportional to the concn. of the manganate in soln. at least up to 5%. The colored crystals are stable, homogeneous, transparent and almost without pleochroism since the pure crystals of chromates and of selenates are but slightly birefringent. These crystals behave like those of phthalic acid, meconic acid, nitrate and oxalate of urea when colored by methylene blue (cf. C. A. 1, 1676; 4, 732; 7, 579), but without modification of the habit; they are conveniently designated as A. When the soln. is sufficiently concd. to deposit crystals of  $\text{K}_2\text{MnO}_4$ , the crystals of A continue to increase in size, but the new layers consist of a mechanical mixt. of very small crystals of the A and of  $\text{K}_2\text{MnO}_4$ , the two kinds having the same orientation, but on account of the opacity of the new deposits, the growth cannot be followed. The structure of the exterior zones is therefore quite different from those of the center and is designated as B. In the case of the sulfates of K, Cs and Rb crystg. in a soln. of  $\text{K}_2\text{MnO}_4$  the first crystals deposited are nearly pure, although the soln. may be concd. with manganate; therefore no crystals of A are deposited. After a few min., when the solution in consequence of its alteration takes on a slightly violet tint, the crystals of the sulfates become colored, but their coloration differs entirely from that of the crystals of chromates and selenates; they are blue-violet with strong pleochroism, not at all agreeing with their birefringence. The flattened pseudo-hexagonal crystals show sectors unequally colored, corresponding to simple crystals and related to B. If the soln. is sufficiently concd. in manganate to allow the formation of crystals of that salt and of the sulfate, two forms of crystals are produced with the same orientation, small in size and sometimes invisible with the microscope. They are related to B, are unstable, following the mode of alteration of the manganate, while crystals of the type A keep indefinitely. Perchlorates of K and  $\text{NH}_4$  crystallizing with  $\text{KMnO}_4$  yield crystals of type A, as long as the soln. is not satd. with permanganate,

but if this satn. occurs there are formed mixed crystals of type *B*, composed of very small crystals of perchlorate satd. with permanganate and of permanganate satd. with perchlorate. These facts explain the form of a curve representing the compn. of the crystals as a function of the compn. of the soln.

L. W. RIGGS.

**Liquid crystals.** ANON. *Engineering* 106, 349-50(1918).—A review.

F. C. HOYT.

**Repression of dissociation.** R. N. DE HAAS. Wageningen. *Chem. Weekblad* 15, 1352-5(1918).—The statement is sometimes found in text-books that in the equation  $K = bc/a$  (where  $K$  is a const.,  $a$  the concn. of undissociated mols., and  $b$  and  $c$  are concns. of the dissociation products), if the factor  $c$  is increased  $b$  must decrease, thus repressing the dissociation. But this is not strictly correct; in the case of addition of one of the dissociated ions, variations in  $a$  must be taken into account. This observation is also true of the degree of ionization. Some text-books state that with  $a$  mols. of a binary electrolyte per unit vol., of which  $x$  mols. are dissociated, addition of an electrolyte yielding  $p$  mols. of a common ion changes the equation for the equil. from  $a - x = Kx^2$  to  $a - x = Kx(x + p)$ . But this neglects the fact that the ionization of the added electrolyte is also repressed, making  $p$  smaller. From mathematical considerations it is shown that the correct equation is  $(K - Kx - x^2)(K - Kx) = K'(x^2 + x^2 + Kx^2 - Kx)$ . H. takes occasion here to revize his definition of complex ions (*C. A.* 11, 3153). The revized definition is: An inorganic complex ion is one which contains a metal and is formed of 1 or more ions from 1 or more mols.

JULIAN F. SMITH.

**Xanthic acids and the kinetics of their decomposition.** H. VON HALBAN AND W. HEGHT. *Z. Elektrochem.* 24, 65-82(1918); *J. Chem. Soc.* 114, II, 222-3.—The rates of decompn. of xanthic acid  $(CS(OEt)SH)(a)$  and of  $CS(OMe)SH(b)$  in water at  $0^\circ$  have been studied. The soly. at  $0^\circ$  of these substances was first found to be: (a), 0.02 mol. per l.; (b), 0.05 mol. per l. The rate of decompn. was detd. by dissolving a known amt. of the Na salt of the acid in question in water, and when the soln. had reached  $0^\circ$ , liberating the acid with a slight excess of HCl, then after a measured interval of time neutralizing with a cooled soln. of  $NaHCO_3$ , and titrating with a 0.02 *N* I soln. It is shown that contrary to the behavior of solns. in org. solvents, the velocity const. in the present case, when calcd. on the basis of a unimolecular reaction, decrease rapidly with decreasing concn. The decompn. is positively catalyzed by H ions. This leads to the assumption that both the undissociated mols. and the ions take part in the reaction. On the basis of this assumption, the dissociation const. of the acids were calcd., and found to be independent of the diln., a fact which confirms the assumption. At  $0^\circ$  the dissociation const. for (b) is 0.034 and that for (a) 0.030. The addition of sulfates (Na, Mg, and  $NH_4$ ) to the decomposing xanthic acids in water soln. strongly retards the action; e. g., 0.25 *N*  $MgSO_4$  reduces the velocity of decompn. to  $1/3$  of the original value, and 3 *N*  $(NH_4)_2SO_4$  reduces it to  $1/4$ . A few velocity measurements have been made in ethyl, methyl, propyl, amyl, and benzyl alc. solns. to complete the data published in an earlier paper (*C. A.* 7, 3876). Measurements were made at  $0^\circ$  on the partition of (a) between water and  $CS_2$ ,  $CHCl_3$ ,  $C_6H_5NO_3$ , light petroleum, benzyl alc., and amyl alc., respectively. The dependence of the partition coeff. on the diln. is in accord with the dissociation const. calcd. from the velocity values. The absorption spectrum of solns. of xanthic acid in light petroleum, 0.5 *N* ethyl alcohol in light petroleum, and in diethyl ether was measured. Although the rate of decompn. is very different in the different solvents, no difference could be observed in the absorption curves.  $CS(OCH_2Ph)SH$  was prepd. from the K salt. It m.  $29^\circ$ ; when quite pure it can be kept for several hrs. In non-hydroxy solvents it has a normal mol. wt. The soly. and rate of decompn. have been detd. in 12 solvents. The satd. soln. at  $0^\circ$  has

the following concn. in these solvents: hexane 0.224 *N*, light petroleum 0.316 *N*, methyl alc. 0.36 *N*, acetic acid 0.41 *N*, nitromethane 1.49 *N*, acetonitrile 3.26 *N*, CS<sub>2</sub> 3.70 *N*, acetone 3.4 *N*, ether 2.93 *N*, benzene 3.33 *N*, ethyl bromide 3.88 *N*, and nitrobenzene 3.15 *N*. The van't Hoff velocity const. was calcd. from the data, and these values as well as those for (a) show that the catalytic influence of the solvent is not removed by the van't Hoff calcn.

D. MACRAE.

**Thermal dissociation of sulfur dioxide.** J. B. FERGUSON. *J. Am. Chem. Soc.* 41, 69-72(1918).—From the equil. const. for the reduction of SO<sub>2</sub> by CO and that for the dissociation of CO<sub>2</sub>, F. calcs. the thermal dissociation of SO<sub>2</sub> from 1000 to 1500°, and from 1 to 0.001 atm. It is found to be somewhat less than that of either H<sub>2</sub>O or CO<sub>2</sub>.

F. C. HOYT.

**Studies in conductivity. IV. The conductivity of alkaline earth formates in anhydrous formic acid.** H. I. SCHLESINGER AND R. D. MULLINIX. *J. Am. Chem. Soc.* 41, 72-5(1919); cf. *C. A.* 6, 566; 8, 3259; 10, 718.—Tables and graphs are given relative to the cond. of Ca and Sr formates in anhydrous formic acid.

ERLE M. BILLINGS.

**The calculation of the position of minimum conductivity in neutralization.** W. D. TREADWELL. *Helvetica Chim. Acta* 1, 97-110(1918).—A mathematical paper dealing with the neutralization and cond. of strong acids and strong bases, of mixts. of univalent strong and weak acids with a univalent base. The minima of cond., which result from the neutralization of dil. aq. solns. of strong and weak acids and their mixts. with alkalis, are calcd. The usual mathematical assumptions were necessary concerning the degree of dissociation of the electrolyte in question. The work with weak acids is found to agree with the observations of Duboux. The calcs. relating to medium strong acids are found to agree with the experimental work of Thiel and Roemer. Tables are given.

ERLE M. BILLINGS.

**Relation between certain galvanomagnetic phenomena.** C. W. HEAPS. *Rice Inst. Phys. Rev.* 12, 340-50(1918).—H. shows on the basis of the electron theory of metallic conduction that the Hall coeff. divided by the specific resistance of the metal is equal to the Corbino const. A simple exptl. method is described for detg. all three effects in the same specimen. In Zn and Cu the Corbino const. is probably independent of the magnetic field. In Bi the three effects are found to behave in the usual manner, but in cryst. graphite the resistance increases rapidly with the magnetic field, the Corbino const. decreases, and the Hall const. increases. From the usual theoretical interpretation, H. concludes that the number of free electrons per unit volume, and the free period of the electron are affected by a magnetic field.

F. C. HOYT.

**Reversal of the Corbino effect in iron.** ALPHEUS W. SMITH. *Ohio State Univ. Phys. Rev.* 12, 337-9(1918).—Chapman (*Phil. Mag.* 32, 303(1916)) has shown the reversal of the Corbino effect in iron at low magnetic fields. S. attempts to find a reversal of the Hall effect in Fe under these small magnetic fields. The reversal is not found, and the Hall and Corbino effects are proportional only throughout a certain range of magnetic field. Hence there is a fundamental difference between the Hall and Corbino effects.

F. C. HOYT.

**The angle of contact made with glass by a mercury surface which is covered with another liquid (abstract).** A. L. CLARK. *Can. Chem. J.* 2, 195.—When pure Hg is in contact with clean glass and covered by air, the angle of contact is large. If the Hg be covered by pure water, the angle is about 4°. When the water is replaced by a dil. H<sub>2</sub>SO<sub>4</sub> soln. the angle becomes 0. The paper is an account of measurements of the angle of contact with acid of various concns. and the conclusions derived from the expts.

E. H.

**Gases and vapors from glass.** R. G. SHERWOOD. Westinghouse Res. Lab. *Phys. Rev.* 12, 448-58(1918).—S. studies the emission of gases and vapors from Corning G-702-P glass in the high vacuum obtained by a Hg diffusion pump. The change of pressure, as measured with a Kundsen vacuum gage, with time serves to give the rate of evolution of the emanations, and integration of the curve gives the total gas emitted. The results indicate that there are two kinds of evolution products, the one resulting from adsorbed products, the other from chem. decompn. of the glass. There is a slow leakage of occluded gases at room temp. Heating at as low as 200° seems to be as effective in removing absorbed gases as at higher temps. The thickness of the adsorbed layer is of the order of magnitude of one mol.

F. C. HOYT.

**Limit and composition of the earth's atmosphere. Aurora borealis, meteors, and shooting stars.** A. VERRONNET. *Compt. rend.* 167, 636-8(1918).—For a fluid mass of density  $\rho$ , temp.  $T$ , under a force of gravity  $\gamma$ , the increase of pressure  $dp = -\gamma dm = -\gamma \rho dr = -\rho dr(\gamma \mu + RT)$ , the last term showing that the relative increase of pressure is proportional to the mol. wt. of the gas  $\mu$ . The results of the application of this formula to the gases of the atmosphere are given in tables and a diagram of curves showing the density and percentages of N, O, A, and H at varying heights from the earth's surface to 300 km. A mean temp. of -60° was assumed, also the presence of an infinitesimal amt. of H at the surface. The percentage of H increases steadily up to 150 km. where it is 11.1; at 200 km., 99.4; at 300 km. it is the only gas present and its extreme height is placed at 500 km., where its pressure equals  $15.10^{-14}$ . O falls to 10% at 50 km., 1.0 at 150, and 0.01 at 190. The percentage of N increases regularly up to 100 km. Between 100 and 150 km., it forms 96% of the air at a pressure less than  $10^{-8}$  atm., which is that of Crooke's tube. This is the region of Aurora borealis, characterized by the green N ray, and placed at 150 km. Beyond 150 km. the N rapidly falls, at 190 it is 2.4%, and at 200 km. 0.6%.

### 3. SUBATOMIC PHENOMENA AND RADIOCHEMISTRY.

GERALD L. WENDT.

**Atomic structure from the physico-chemical standpoint.** ALFRED W. STEWART. Univ. Glasgow. *Phil. Mag.* 36, 326-36(1918).—After enumerating the actual radioactive and chem. phenomena that must be taken into account in devising a theoretical atom, S. proposes a structure built up of three sets of orbits, the innermost a small circular orbit of negative electrons, the second a somewhat larger circular orbit of positive electrons, and the outermost a cometary or elliptical orbit of electrons (negative), in which path a high degree of ellipticity will take the electrons at a certain part of their

course relatively very far from the two inner or nuclear orbits. S. then presents evidence favoring the proposed structure. Beta ray changes and their accompanying change of valence originate in the innermost circle, are very fundamental in character and irreversible. Alpha ray changes are brought about by the collision of two systems each containing two positive and one negative electrons, thus avoiding the assumption of the existence of helium atoms in the nucleus. Alpha changes are also fundamental and irreversible. Reversible changes of chem. valence are produced in the outer or cometary orbit. Elements showing different chem. valencies probably possess a high degree of ellipticity of orbit and are most subject to outside influences when the electrons are farthest from the nucleus. The fact of valencies differing often by two is explained by a short life of the intermediate valence state, which is illustrated in the intermediate radioactive products where two successive beta ray changes take place, the intermediate product being always very short lived in comparison with the other two. The term "isobare" is proposed for elements of the same at. wt. but different chem. character.

S. C. LIND.

**Atomic number and frequency differences in spectral series.** HERBERT BELL. Univ. Mich. *Phil. Mag.* 36, 337-47(1918).—B. has numerically tested the law that the square root of the doublet and triplet differences (of wave length) for elements of the same column of the periodic system is proportional to the at. weights. B., however, substitutes at. number for at. wt. By plotting the square root of the difference ( $\sqrt{\sigma}$ ) against at. number ( $N$ ), very satisfactory linearity was obtained in a number of the periodic columns. A similar relationship was found by Kayser and Runge's frequency intervals in the nitrogen column. A frequency difference of  $41.8 \text{ cm}^{-1}$  in the phosphorus series also seemed to fit. Linearity is also indicated for the He column. Runge and Precht's logarithmic law is not an improvement. In two columns of the periodic table a two-fold linearity was found, the lines branching at the element at which the branching of the periodic columns begins.

S. C. LIND.

**The electron theory of metallic conductors applied to electromagnetic distribution problems.** L. SILBERSTEIN. London. *Phil. Mag.* 36, 413-20(1918).—The electron theory of metallic conductors has been treated exclusively from the standpoint of current conduction and allied phenomena. The present is a mathematical application of the theory to electrostatic distribution in metals.

S. C. LIND.

**Bohr's hypothesis of stationary states of motion and the radiation from an accelerated electron.** G. A. SCHORR. Univ. Coll. of Wales, Aberystwyth. *Phil. Mag.* 36, 243-51(1918).—A mathematical discussion of Bohr's hypothesis *A* regarding the so-called stationary states of motion, from which it is concluded: (1) that the hypothesis is incompatible with the electromagnetic equations of Maxwell and Hertz taken together with the Poynting energy flux for the free ether, at least for the case of uniform circular motion of the electron, and almost certainly for any other form of motion of translation. (2) Hypothesis *A* can be made compatible by a restatement postulating no change in the electromagnetic energy of the electron in spite of the emission of radiant energy. For neither the accelerating energy nor the electromagnetic energy of an expanding electron is available as a source of the radiant energy.

S. C. L.

**A new secondary radiation of positive rays.** M. WOLFFKE. Zurich. *Phil. Mag.* 36, 270(1918).—A note of correction to the effect that the claim of (*C. A.* 12, 563), a new secondary penetrating radiation which was believed to be the characteristic radiation of tin and lead, was due to exptl. error, and that it has now been found to be due to excitation by positive ions.

S. C. LIND.

**The scattering of light by air molecules.** R. W. WOOD. Johns Hopkins Univ. *Phil. Mag.* 36, 272-3(1918).—W. suspects that the recent results of Strutt (*C. A.* 12, 2488)

on the scattering of light by air molecules may have been influenced by the effect of ultraviolet light in producing a cloud. This is a source of error which W. encountered with a similar apparatus which forced him to abandon the expts. He now suggests repetition, using air vaporized from liquid air to avoid use of a drying agent which he believed to be connected with the cloud formation.

S. C. LIND.

A comparative study of the flame and furnace spectra of iron. G. A. HEMSALECH. Univ. of Manchester. *Phil. Mag.* 36, 209-31 (1918).—A comparison of the Fe lines in an electric carbon tube resistance furnace with those obtained by the introduction of Fe salts into gas flames with the object of ascertaining whether the lines are of purely thermal or of chemical origin. It is concluded that up to nearly 2400° the spectra are produced by the action of heat on a chem. compd. of Fe not on the metal itself. Fe lines have been observed as low as 1500°. The lines emitted by Fe compds. in flames are identical with those obtained in the furnace at corresponding temps. up to 2400°; hence it is concluded that the mode of excitation is the same in both cases, namely, chem. dissociation of an Fe compd. by the action of heat. The character of the spectrum is independent of the nature of the compd.; chlorides, oxides, etc., give the same spectra in both sources of heat at the same temp. The name *thermochemical excitation* is used to designate this cause of emission. These spectra differ entirely from those given by the same compds. in the explosive region of the air-coal gas flame, where the emission is due to chemical excitation at comparatively low temp.

S. C. LIND.

The origin of the line spectrum emitted by iron vapor in an electric tube resistance furnace at temperatures above 2500°. G. A. HEMSALECH. Univ. Manchester. *Phil. Mag.* 36, 281-97 (1918); cf. preceding abstr.—The results of the present expts. have led to the conclusion that the so-called high-temp. spectrum of Fe, which is emitted above the temp. of the boiling metal, is not caused by purely thermal action, but requires the joint action of electric forces. The furnace spectrum of Fe at 2700° is entirely different from its flame spectrum at the same temp. The behavior of certain groups of lines indicates that the high-temp. spectrum of Fe approaches in character that of its arc spectrum. It is exptly. shown that an ionization current will pass through the Fe vapor in a tube furnace. As in the elec. spark, the line emission of Fe vapor in the furnace does not stop abruptly on the removal of the field. The spectrum emitted after the current is broken is not controlled by the temp. of the furnace; a certain group of lines at 4957 is visible at 2300° which under ordinary circumstances cannot be observed at 2400°. Cu, Ag, and Zn vapors do not give line emission at 2700° in the elec. tube furnace, probably because their vapors possess a low degree of elec. cond. as compared with Fe, Co and Ni. This view is supported by observation of the spark spectrum of the same metals. Attempts to excite a line spectrum in Fe vapor by thermal action alone led to negative results. The following classification of excitation of light radiations has been made by H: (1) Thermal action alone. No line or band spectrum has been observed in this class for Fe vapor. (2) Thermo-chem. excitation. Action of heat on chem. compds. without dissociating them. Observed in the mantles of all flames so far examined and in the elec. tube furnace to nearly 2500°. (3) Chemical excitation, involving the complete decomposition at relatively low temp. of an Fe compd. and the formation of a new one owing to the strong chem. affinity between Fe and N. This is met with in the explosion region of the air-coal gas flame and gives rise to a highly developed spectrum. (4) Thermo-elec. excitation accompanies elec. discharge through Fe vapor already highly ionized by heat action. The ordinary elec. arc between Fe poles is a special case where the degree of ionization is maintained by the application of high voltage. (5) Elec. excitation occurs in the capacity and self-induction sparks between Fe electrodes at ordinary temp.

S. C. LIND.

**Some properties of the active deposit of radium.** S. RATNER. Univ. Manchester. *Phil. Mag.* 36, 397-405(1918).—R. has investigated the spread of active material across a small air space from an activated plate to a receiving disk. The phenomenon has hitherto been known only as source of error in recoil and other radioactive measurements. Very puzzling phenomena were encountered by R., the elucidation of which was not accomplished. The spread of Ra A, for example, was found to be proportional to the quantity of Ra Em producing the Ra A, in exposures of the same length, but not proportional to the quantity of Ra A as a function of the time of exposure. Very short exposures led to the spread of almost as much Ra A to the opposite disk as much longer exposures. The washing and heating of the plate previous to the collection of Ra A was found to play an important but unexplained role. A very definite half period for the spread of Ra A was found, having the value 1.4 min. This suggested unknown intermediate products, which other evidence, however, disproved. Owing to the influence of the electric wind, a field much enhanced the spread of active material, but the direction of the field was immaterial, and a strong air current between plate and disk prevented any spread taking place. In many expts. a high field was employed in the direction to withhold the recoil atoms from the receiving disk. The chem. or phys. nature of the plate surface had no influence. Although not leading to an explanation of the phenomena, valuable information was gained, showing that the quantity of material spread is so great as to vitiate all previous results on the deposit of beta ray recoil atoms. It was also established that the proportion of recoil atoms of Ra B carrying a negative charge is certainly less than 1 to 100,000. S. C. LIND.

**Photolysis and electrolysis.** EMIL BAUR. Federal Tech. H. S., Zürich. *Helvetica Chimica Acta* 1, 186-201(1918).—Insolated uranyl salt solns. act as if they contained both a higher and a lower state of oxidation, i. e., in reacting with oxalic acid they are able both to oxidize to  $\text{CO}_2$  and to reduce to CO;  $5 \text{U}^6 + \text{light} = 3\text{U}^5 + 2\text{U}^4$ , which reacts as follows:  $\text{U}^5 + \text{C}_2\text{O}_4'' = \text{CO}_2 + \text{U}^6$ ; and  $\text{U}^4 + \text{C}_2\text{O}_4'' = \text{CO} + \text{U}^6$ . Insolated uranyl salts, however, are also fluorescent, indicating a dislocation or loosening of electrons. This leads B. to the assumption that the action of the light is not a complementary oxidation and reduction of different U atoms, but is a rearrangement of the electrons within single mols. in such a manner that the mols. become elec. polarized, one terminal of the mol. being positive and the other negative. Both anodic oxidation and cathodic reduction can thus be produced by the same mol. due to the p. d. within itself. The e. m. fs. so generated are calcd. on the basis of the quantum theory and are of the order of 2.4 v. for yellow light, 3.2 v. for blue, 5.5 for ultra-violet, and about 100,000 v. for the shortest  $\gamma$ -rays. On this conception the action of the fluorescent dyestuffs in sensitizing other reactions is due to simultaneous oxidation and reduction. The decompn. of Eder's soln. in light by eosin is represented as:

and the sensitizing action of quinine on the oxidation of HI by O in light is

The same interpretation is given to a number of newly demonstrated photochemical oxidations and reductions, including:  $\text{HgCl}_2$  + cane sugar by uranyl salts in light; oxidation of eosin by  $\text{HgCl}_2$  in light; the oxidation from ferrous ion to ferric by  $\text{HgCl}_2$  in the presence of rhodamine in light; the photochemical oxidation of uranyl

formate; the self-electrolysis of AgCl in light to produce its constituent atoms; the photochemical formation of HCl and of ozone.

G. L. WENDT.

#### 4. ELECTROCHEMISTRY.

COLIN G. FINK.

**Recent hydroelectric development in Tasmania.** L. W. ALWYN SCHMIDT. *Elec. World* 73, 75-6(1919).—There are 70,000 h. p. now available. This has given birth to a new electrochem. center (Zn, carbide, etc.). The elec. features of the plant are described at length.

C. G. F.

**Developing our electrochemical resources.** C. G. SCHUEDERBERG. *Elec. J.* 16, 3-5(1919).—A general survey in which the author, in his characteristic forceful style, points out the national economic importance of fostering and expanding our electrochem. industries.

C. G. F.

**Electrochemistry and electrometallurgy.** ANON. *Elec. Rev.* 74, 9-10(1919).—A brief review covering elec. furnaces, ferro-alloys, brass, Cottrell process, potash, etc.

C. G. F.

**The electrochemical industry of Italy.** F. PFITZNER. *Z. angew. Chem.* 30, I, 321; *Elektrotechn. Z.* 39, 265(1918).—A review. The industry has more than doubled its total output of electrochem. products within the last 8 yrs.  $\text{CaC}_2$ , caustic, bleaching powders, hypochlorites, Cl, N fixation (Pauling), cyanamide, ferro-Si, Si and Ba salts are among the chief products of Italy. Details are given.

C. G. F.

**Notes on electric-furnace problems.** J. L. MCK. YARDLEY. *Bull. Am. Inst. Mining Eng.* 1918, 1593-8.—Two general classes of elec.-furnace problems are cited: (1) those relating to the best utilization of the elec. power inside the furnace; and (2) those connected with the bringing of the elec. power to the point where it is to be utilized. An example is given showing a method for detg. the max. capacity and approx. performances of a new furnace to operate at 160 v. on a 60-cycle circuit. Plenty of test data should be available for checking purposes.

W. E. RUDER.

**The status of the electric steel industry.** EDWIN F. CONE. *Iron Age* 103, 60-2 (1919).—A review giving particulars as to every important elec. steel furnace in the world. There are over 800 elec. steel furnaces operating throughout the world to-day, 287 in U. S., of which number over  $1\frac{1}{2}$  are Heroult. Great Britain is next to U. S., the largest elec. steel producer.

C. G. F.

**The electric smelting furnace of Grönwall-Dixon.** CARL IRRESBERGER. *Stahl u. Eisen* 38, 90-2(1918).—This furnace was originally designed by Grönwall and used in Sweden for smelting ores. Then it was introduced into U. S. and modified there by Joseph L. Dixon. Construction and operation of the furnace are described and the favorable results obtained at the Works of the Railway Steel Spring Co. in Detroit are recorded. The Grönwall-Dixon furnace seems to be an improvement in elec. smelting and steel manufacture. Diagrams are shown.

TH. VERHEGGEN.

**The great electric steel works at Ugine.** ANON. *J. four électrique* 27, 193-4 (1918).—The plant comprizes an elec. steel found ry, a ferro-alloy foundry and an electrode factory. The capacity of the elec. furnaces is 60,000 tons per yr. Details are given.

C. G. F.

**The design and operation of a small Kjellin furnace.** GEO. H. STANLEY AND W. BUCHANAN. *Met. Chem. Eng.* 18, 349-53(1918).—A description of the Kjellin elec. induction furnace installed on the Witwatersrand, S. Africa, for the manuf. of elec. steel castings for stamp-mill shoes and dies. Instead of elaborate water-cooling, air

circulation alone is depended upon for cooling the coil. An asbestos-board ventilating cowl is placed over the center and connected with the flue. Monel metal was used in the construction wherever possible to cut down undesirable magnetic fields. A tar-chromite lining was found best. The furnace was started with a charge of molten cast Fe. The chief furnace trouble has been the formation of a crust of solid metal. The product so far has been non-uniform in C content and the castings have been imperfect, but with increased experience these defects are being overcome.

W. E. RUDER.

**Application of the electric furnace to the metallurgy of iron and its alloys.** H. ETCHILLS. *Electrician* 81, 734(1918).—An address. C. G. F.

**Development of an electric furnace for annealing, treatment and forging of steel.** WIRT S. SCOTT. *Chem. Met. Eng.* 19, 86-9(1918).—See C. A. 12, 2165. C. G. F.

**Copper extraction from pyritic ashes.** ANON. *Eng. Mining J.* 106, 987(1918).—A new method for the electrolytic extn. of Cu from pyritic ashes, described in *L'Industrie*, is based on the electrolytic conversion of CuS or CuSO<sub>4</sub> into CuCl<sub>2</sub> or CuCl by the action of Cl at the anode. If in an electrolytic bath containing HCl in soln. the anode is surrounded by a mass of pyritic scoria, the Cl liberated by the H attacks the oxides, sulfates, or sulfides of Cu more rapidly than it attacks the oxides of iron, and combines with them to form CuCl<sub>2</sub>. Cu loss by this method is only 0.1% C. G. F.

**The present status of electric brass melting.** H. M. ST. JOHN. *Chem. Met. Eng.* 19, 321-8(1918); cf. C. A. 12, 1439.—A survey of the applications of elec. furnaces to the melting of brass and other Cu alloys. The advantages and disadvantages of different types of furnaces are discussed. Of the 4 types of elec. furnaces in com. use, only two are suitable for use with alloys high in Zn. One, the vertical-ring induction furnace, is of high efficiency, but is somewhat limited as to its application and is not flexible enough for general foundry work. The indirect resistance, indirect radiation furnace is less efficient and has a lower rate of production in proportion to its holding capacity, but is more flexible and better suited for general foundry work. Elec. crucible furnaces are reliable and effective, but in this field give little hope of profitable application except under unusual conditions. Cf. Bailly furnace, C. A. 12, 1859. W. E. RUDER.

**Nitrogen-fixation furnaces.** E. KILBURN SCOTT. *Trans. Am. Electrochem. Soc.* 34, preprint; *Gen. Elec. Rev.* 21, 793-803(1918); *Chem. Met. Eng.* 19, 411-4(1918).—Furnaces for the fixation of N are classified into 3 groups depending upon the means employed to direct the arcs and typical well known furnaces of each type are described. The effect of phase, balance, starting losses, electrodes, stability of the arc, power factors, air supply, cooling the gas, preheating, absorption, etc., are described. Diagrams and sketches are given showing furnaces, arcs and elec. characteristics.

W. E. RUDER.

**Electrical features of Muscle Shoals nitrate plant.** ANON. *Elec. Rev.* 74, 52 (1918).—The installation includes a 70,000 K v a 12,000 volt turbine. C. G. F.

**Aluminium (bauxite) deposits and the production of aluminium.** ANON. *Engineering* 106, 163, 191, 218(1918).—Due to the shortage of Cu, the use of Al has been considerably extended. The Hungarian bauxite deposits of the Jurassic period are variously estd. at from 18 to 30 million tons. A table is given of the analysis of bauxite from 25 different sources, varying in Al<sub>2</sub>O<sub>3</sub> content from 29 to 69%, the principal impurities being SiO<sub>2</sub> and Fe<sub>2</sub>O<sub>3</sub>. A rather complete summary is given of various uses of Al and processes for its manuf. with some statistics as to the world distribution of Al manuf. W. E. RUDER.

**Aluminium as a substitute for copper for transmission lines.** M. WYSSLING. *Bull. soc. Elec. suisse* 7, 117(1918); *Elektrotechn. Z.* 39, 258(1918).—A review.

C. G. F.

**Commercial uses of chlorine.** V. R. KOKATNUR. *Trans. Am. Electrochem. Soc.* 34, preprint; *Chem. Met. Eng.* 19, 667-71(1918).—A very comprehensive review of the present and possible uses of Cl and Cl compds. in metallurgy, warfare, inorg. salts, org. solvents, pharmaceuticals and intermediates.  $\text{SiCl}_4$  and  $\text{TiCl}_4$  were largely used in smoke screens. Among the gases used in warfare, more than 50% were Cl compds. and probably 95% were made directly or indirectly by the use of Cl. Chloroacetone, trichloromethyl chloroformate ( $\text{ClCOOCCl}_3$ ), called superpalite and phenyl-carbylamine chloride ( $\text{C}_6\text{H}_5\text{NCCl}_2$ ), were used as lachrymators. Benzyl chloride and chloropicrin ( $\text{C}(\text{NO}_2)_3$ ) found use as tear gas. Mustard gas (dichlorodiethyl-sulfide) and "sneezing gas" (diphenylchloroarsine) were also much used. As org. solvents Cl compds. are of great value. The most extensively used is  $\text{CCl}_4$ ;  $\text{CHCl}_3$ ,  $\text{C}_2\text{H}_5\text{Cl}$ , "Dutch Liquid" and  $\text{CH}_3\text{OHCH}_2\text{Cl}$  are examples of widely used solvents. Tetrachloroethylene is an ideal dry-cleaning solvent. The problem of turning this vast primary by-product to man's service in times of peace is one which must be promptly met by manufacturers.

W. E. RUDER.

**Electrolytic refining of antimony.** Y. C. WONG. *Chem. Met. Eng.* 19, 509(1918).—The extg. soln. was prepd. by the reaction  $3\text{CaO} + 4\text{S} = 2\text{CaS} + \text{CaS}_2\text{O}_3$ . Several 40-cc. portions of Sb exts. were added, giving on analysis 0.962 g. of Sb to which were added 15 cc. of CaS (d. 1.18), 1 g. NaCl, 4 cc. of 10% NaOH soln., and the whole was dild. to 400 cc. with hot  $\text{H}_2\text{O}$ . The cathode was a Pt cylinder of 39.3 sq. cm. surface and the anode a Pt spiral. With a voltage of 1 to 1.2 and a current of 0.4 amp., 90% of the Sb was deposited in 1 hr. Too much NaOH will give a black non-coherent deposit. The cost of refining by this process is estd. at 5 c. per lb. W. E. RUDER.

**The Siemens-Billiter process.** J. NUSSBAUM. *Z. Elektrochem.* 24, 50-2(1918).—Polematical.

C. G. F.

**Effect of cold upon battery performance.** KENNEDY RUTHERFORD. *Elec. Rev.* 71, 718-9(1918).—R. points out that the decrease in available capacity with lowering of temp. is gradual in the case of the Pb battery but that in the case of the Ni-Fe battery, though gradual down to 5°, it is very rapid from there on. R. suggests that whenever either battery is to be exposed to low temp. for any length of time, it be encased in a double-walled box on the Dewar flask principle.

C. G. F.

**The sign of the potential.** DEUTSCHE BUNSEN GESELLSCHAFT. *Z. Elektrochem.* 24, 40(1918).—The Bunsen Society recommends the negative sign for the Zn electrode, the positive sign for the Ag electrode, etc. (This corresponds to the recommendations of the Am. Electrochem. Soc.)

C. G. F.

**Mercury arc rectifiers.** ANON. *Elektrotechn. Z.* 39, 267(1918).—A brief announcement of a new Schott-A. E. G. glass rectifier with a capacity as high as 100 amp. at 250 volts. This is more than any of the present glass rectifiers will carry.

C. G. F.

**A neon arc lamp for direct current.** F. SCHROETER. Berlin. *Z. Elektrochem.* 24, 132-7(1918).—According to Bouty (*Compt. rend.* 138, 1691(1904)) the dielec. cohesion for Ne is lower than that of any other gas. A Moore tube of 20 mm. inside diam. containing Ne gas plus a little He consumed but 0.26 watt per Hefner candle compared with a similar argon Moore tube consuming 45 watts per Hefner c. In the Ne (1 mm. p.) tube the potential drop is distributed as follows: At the electrodes 30 v., Ne arc or luminous column 110 v., resistance in series 80 v. The relation between amperes ( $i$ ) and volts ( $e$ ) is represented by the following equation:  $e = 114 + (26/i)$ ,

for a tube 21 mm. inside diam. containing 1 mm. Ne (+ little He). Including the watt consumption of the rheostat connected in series with the lamp, the efficiency is 0.52 w. per horizontal Hefner candle. Contrary to the behavior of metal filament and Hg vapor lamps, the w. p. c. attains a minimum (at about 0.29 w. p. c. American) and then increases again as the c. d. is increased (curve is shown). The light absorption of Ne is very slight. On account of the low ionization voltage of metal vapors ( $\text{Hg} = 4.9$  vs.  $\text{Ne} = 16$ ) it is necessary to employ a cathode which does not produce these metal vapors. It was found that Tl, as cathode, does not contaminate the Ne column with Tl vapor; Hg, however, does. The alkali metals proved to be the best cathode metals

from a light efficiency point of view but they attacked the walls too rapidly. Skaupy had alloyed the alkali metals with Hg or Tl or Pb (U. S. pat. 120,770). S. improves upon Skaupy's cathodes by using definite compounds, e. g.,  $\text{NaHg}$  and  $\text{NaHg}_2$ . Since the heat of formation of these compounds is very high and the Hg% is high, it follows that the concn. of free Na in the gas phase must be low. By expt. S. found that the walls of the glass tube were but slightly attacked when  $\text{NaHg}$  and  $\text{NaHg}_2$  cathodes were used and the lamps remained clear for several 1000 hrs. The Hg vapor p. was so low that it did not noticeably affect the Ne spectrum. A cathode composed of Cd and Tl (about 82% Tl, m. p.  $200^\circ$ ) was finally found to be most efficient. The lamp shown in the fig. is made of glass: 1 is the Tl-Cd cathode, 2 is the condensing chamber, 3 is an Fe anode, 20 sq. cm. per amp. The tube is filled with gas (75% Ne, 25% He) at 1 mm. p. This gas is practically as efficient as pure Ne. Photometer curves are shown. This Schroeter lamp is in reality a half-watt lamp which will burn brightly for more than 2000 hrs. The lamp does not grow hard since Ne is not occluded. The lamp may find wide application in signal service on account of its penetrating red rays.

C. G. F.

**A neon lamp of low watt consumption for signal and indicator service.** ORRO SCHALLER. Berlin. *Z. Elektrochem.* 24, 131-2 (1918).—There has been an urgent demand in Germany for a lamp which would not consume more than 1 watt and would operate on 220 volt. Neither C nor W filament lamps could be made satisfactorily to meet these specifications. In the new lamp developed, the light is due to a cathodic glow discharge. A small glass bulb about 1 or 2 cm. in diam. is filled with Ne (+ He) gas at 7.6 mm. pressure. The electrodes are Fe, spaced 5 mm. apart. The light intensity is dependent upon the area of the cathode surface and the pressure of the gas. The voltage increases slowly with increase in amp. The voltage drop between terminals is pretty nearly equal to the voltage drop at the cathode since the spacing of the electrodes is so close. No high-tension starting voltage is necessary; the lamp will begin to glow instantly on 220 v. A small resistance is connected in series with the lamp and det. the max. current that will pass through the lamp. About 90% of the emitted Ne light falls within the range  $650\mu\text{m}$  to  $570\mu\text{m}$ .

C. G. F.

**Tungsten crystal wire as glow-lamp filament.** O. ELY. *Z. Ver. deut. Ing.* 62, 15-20 (1918).—After a brief historical review of the first metallic filaments used in elec. incandescent lamps, the different methods of manufacturing filaments for W lamps are stated. The author then describes at length a new patented process (Julius Pintsch Co., Berlin) for the manuf. of filaments made of a long crystal of metallic W. These wires have not only the advantage of a greater flexibility and ductility, but also the property of not becoming brittle after long burning at high temps. (about  $2600^\circ$ ). The

single crystal that composes the filament does not give way to such changes. *Manufacture of tungsten crystal wire:* The  $WO_3$  is pulverized as finely as possible and is completely reduced by heating in a H atm. to produce pure W metal, a brilliant black-brownish metallic powder. To this W is added a carefully detd. quantity of  $ThO_2$ , which addition is of very great importance for the formation of the crystal and the ductility of the wire; finally a colloidal binding material is added in very small quantity. From this doughy mass filaments of various diameters are formed, just as in the old paste processes. After the extended "threads" have been dried at a moderate temp. they are placed, 8 at a time, into the treating app., where the transformation into pure metallic crystals takes place. The treating app. consists essentially of a glass cylinder closed at both ends and provided with two contacts joined by a helix of heavy W wire. The filaments to be treated are passed through the axis of this glowing helix by means of a simple mechanism; during the operation the W helix is traversed by a current of 40 amp. and 25 volts; thus the filaments to be treated are raised rapidly to a temp. of 2600–2700°. A continuous current of reducing gas passes through the glass cylinder. Of very great importance in the formation of infinitely long crystals is the speed with which the filaments are moved through the hot zone. This speed must be less than the speed of crystn. in order to allow the crystal to grow gradually at the expense of the small adjacent crystals. If the linear velocity of the filaments passing through the helix is too great a filament composed of several crystals is obtained; this is very fragile, breaking at the interfaces of the successive crystals. Filaments composed of a single W crystal retain all their good properties even after many hrs. of burning; they retain their ductility and softness and resist vibration and shock, which is not the case with some drawn W filaments. Comparative tests made under the same conditions with a lamp provided with Pintsch W crystal filaments and a lamp provided with drawn W filaments, have shown that after a life of 1200 hrs. the filament made of a W crystal had not given rise to the slightest trace of deposit on the walls of the bulb, whereas the filament of drawn W was more or less disintegrated, the interior of the bulb being covered with a light black deposit; it seems therefore that the new Pintsch process offers an additional advantage on this account. Numerous photomicrographs of the new filaments and some of the old-fashioned filaments are shown.

Dry-cell electric battery. H. R. PALMER. U. S. 1,286,750, Dec. 3. Structural features.

**Electrolytic cell.** L. D. VORCE. U. S. 1,286,844, Dec. 3. The pat. relates to structural features of a cell adapted for electrolysis of NaCl soln. to produce NaOH and Cl.

**Electrolytic apparatus for production of tin fluosilicate from tin anodes.** R. L. WHITEHEAD. U. S. 1,287,156, Dec. 10. An electrolyte of HF is employed and removable cathodes which may be formed of Sn, Cu or Pb are arranged alternating with impure Sn anodes. The cathodes are enclosed in removable porous compartments which serve as diaphragms between them and the anodes and prevent deposition of Sn on the cathodes.

**Electric furnace.** O. SAHLIN. U. S. 1,286,794, Dec. 3. The furnace is of the arc type and is adapted for smelting or refining metals.

**Calcium cyanamide.** AKTIEBOLAGET NITROGENIUM. Swed. 43,668, Feb. 20, 1918. Before introduction into the furnace, the  $\text{CaC}_2$  is mixed with an inactive material to increase the m. p. of the mass, and prevent sintering. The mass is also rendered less compact, and the amt. of catalyzer required to accelerate the reaction is less. The addition of inactive material does not exceed 35% of the wt. of the carbide. Cf. also 43,666, Feb. 20, 1918, similar process.

## 6. INORGANIC CHEMISTRY.

H. I. SCHLESINGER.

**The compound  $\text{H}_2\text{B}_4\text{O}_6$  and its salts.** R. C. RAY. *J. Chem. Soc.* 113, 803-8 (1918); cf. *C. A.* 9, 276.—Expts. are described having for their object the isolation of a lower oxide of B, believed from the previous work to be present in so-called amorphous boron. A mixt. of Mg and  $\text{B}_2\text{O}_3$  (1:3.5) was heated for 3 hrs. to bright redness in a current of H in a MgO-lined crucible. After it had cooled in H, the mass was powdered, mixed with half its weight of  $\text{B}_2\text{O}_3$ , heated again as before, powdered, and left in contact with water 1-3 days to remove traces of  $\text{Mg}_3\text{N}_2$ . The soln. was filtered and boric acid removed by shaking *in vacuo* for several days with pptd.  $\text{Mg}(\text{OH})_2$  and filtering off insol.  $\text{Mg}(\text{BO}_2)_2$ . In analysis advantage was taken of the fact, previously discovered, that solns. of lower oxides of B when evapd. with excess of lime and the residue ignited to const. wt., are not oxidized and the increase in wt. corresponds to the wt. of lower oxide in soln. In 5 solns. each from a different fusion, the ratio B/Mg was closely 4 in all cases and the ratio  $\text{B}_2\text{O}_3/(\text{residue less MgO})$  varied from 1.112 to 1.132, average 1.124, while  $2\text{B}_2\text{O}_3/\text{B}_4\text{O}_6$  is 1.129. Another prepn. was treated with water four times and the exts. were analyzed separately. Although the solns. became more and more dil., their compn. remained practically const., leaving no doubt that a compd.,  $\text{MgO} \cdot \text{B}_4\text{O}_6$ , was present. Mol. wt. detd. from the f. ps. of the solns. assuming 75% ionization agreed well with the theory. This compd. could not be isolated, but on treatment with the equiv. of KOH and evapn. *in vacuo* to small bulk practically all Mg sepd. On further concn. *in vacuo* the K salt sepd. as a crust and was purified by several recrystns. and dried *in vacuo* at 80-90°. It is stable in absence of moisture. Analyses and mol. wt. detns. agreed well with the formula  $\text{K}_2\text{B}_4\text{O}_6$ . If the B atoms are linked in a single chain, the oxide must be given the formula  $\text{BO}:\text{BO}:\text{BO}:\text{BO}$  and the acid the formula  $(\text{HO})\text{BO}:\text{BO}:\text{BO}:\text{BO}(\text{OH})$ .

A. R. MIDDLETON.

**Fusion of sodium hydroxide with some inorganic salts.** M. C. BOSWELL and J. V. DICKSON. *J. Am. Chem. Soc.* 40, 1773-9 (1918).—Reactions were found to take place involving decompn. of water, one mol. of O going to effect oxidation and two mols.

of H being either evolved or fixed. With  $\text{NaAsO}_2$  and  $\text{FeSO}_4$  the extent of oxidation was found equivalent to the H evolved; with  $\text{SnCl}_2$  and  $\text{V}_2(\text{SO}_4)_3$  much H was evolved; with  $\text{Ce}(\text{SO}_4)_3$  a less amt.; with  $\text{U}(\text{SO}_4)_2$  only a small amt. Neither  $\text{NaNO}_2$  nor  $\text{Na}_2\text{SO}_3$  was oxidized.

A. R. M.

**Action of sodium hydroxide on carbon monoxide, sodium formate and sodium oxalate.** M. C. BOSWELL AND J. V. DICKSON. *J. Am. Chem. Soc.* 40, 1779-86(1918).—CO heated with excess of NaOH at temps. at which formate is transformed to oxalate was oxidized almost quant. to carbonate with evolution of approx. an equiv. amt. of  $\text{H}_2$ . At temps. far below those at which formate and oxalate alone are decompd. NaOH carries both of them almost quant. to carbonate with evolution of the equiv. amt. of  $\text{H}_2$ . In a discussion of the general reaction involving replacement of carboxyl by H in alk. fusions, e. g.,  $\text{CH}_4$  from  $\text{AcONa}$ ,  $\text{C}_6\text{H}_6$  from  $\text{BzONa}$ , a probability is shown that simultaneous oxidation and reduction by the elements of water are involved.

A. R. MIDDLETON.

**Preparation and properties of aniline chlorostannate.** J. G. F. DRUCE. *Chem. News* 117, 346-8(1918); cf. *C. A.* 12, 1622; 13, 99.—Ten g. nitrobenzene, 15 g. tin and 80 cc. concd. HCl, added in 10-cc. portions, were warmed until the metal had dissolved. On cooling at this stage  $\frac{2}{3}$  of the tin was left as  $\text{SnCl}_4$ — $2 \text{C}_6\text{H}_5\text{NO}_2 + 3\text{Sn} + 14\text{HCl} = (\text{C}_6\text{H}_5\text{NH}_2)_2\text{H}_2\text{SnCl}_4 + 2\text{SnCl}_4 + 4\text{H}_2\text{O}$ —but upon adding 200 cc. warm dil. HCl and 18 g. aniline a nearly quant. yield was obtained. If  $\text{SnCl}_2$  be used instead of the metal, reduction is complete in less time but more uncombined  $\text{SnCl}_4$  remains in soln. The equation is  $2\text{C}_6\text{H}_5\text{NO}_2 + 6\text{SnCl}_2 + 14\text{HCl} = (\text{C}_6\text{H}_5\text{NH}_2)_2\text{H}_2\text{SnCl}_4 + 5\text{SnCl}_4 + 4\text{H}_2\text{O}$ . The chlorostannate could also be obtained by shaking aniline with twice its wt. of  $\text{SnCl}_4 \cdot 5\text{H}_2\text{O}$  and by reducing azobenzene and hydrazobenzene with  $\text{SnCl}_2$  and HCl. Anhydrous aniline chlorostannate is colorless when pure, m.  $293^\circ$ , with slight decompn.; 100 cc. water at  $16^\circ$  dissolves 28 g.; the soln. hydrolyzes only when boiled some time or after standing several days; a few drops of dil. HCl or  $\text{HNO}_3$  prevents or greatly retards sepn. of tin oxide. The HCl soln. darkens on keeping, particularly in sunlight, and becomes black and opaque; a little nitrobenzene hastens the darkening and the color is removed by warming with  $\text{SnCl}_2$  soln. or with Zn; the dark compd. is sol. in  $\text{Et}_2\text{O}$ . Aniline chlorostannate is sol. in  $\text{EtOH}$ , insol. in  $\text{Et}_2\text{O}$ ,  $\text{CHCl}_3$ ,  $\text{CCl}_4$ ,  $\text{C}_6\text{H}_6$ , ligroin and glacial AcOH. Addition of a few drops of  $\text{K}_2\text{Cr}_2\text{O}_7$  soln. to a soln. of the salt in concd.  $\text{H}_2\text{SO}_4$  produces an intense blue color; addition of aq. soln. of the salt to a soln. of bleaching powder produces an intense violet color; aq. and dil. acid solns. give a bright yellow color when dropped on paper or wood; pure filter paper is not colored. Total Cl in the compd. could be detd. by titration with 0.1 N NaOH and phenolphthalein. The salt can be used in Skraup's synthesis of quinoline instead of aniline and nitrobenzene with improved yield and fewer operations. To 50 g. each of aniline chlorostannate and glycerol 50 g. concd.  $\text{H}_2\text{SO}_4$  was slowly added and the mixt. heated gently for 1 hr.; the soln. was cooled, dild. with 400 cc. water and  $\text{NaNO}_2$  soln. added till starch-KI gave a blue color, allowed to stand 1 hr., then boiled 20 min., cooled and made alk. with NaOH, distd. with steam and extd. with  $\text{Et}_2\text{O}$ ; this gave 20 g. quinoline, 80% of theoretical. *o*-Toluidine chlorostannate, prepd. from *o*-nitrotoluene similarly to the aniline salt, also gave a good yield of 8-methylquinoline by the above modification of Skraup's synthesis.

A. R. MIDDLETON.

## 7. ANALYTICAL CHEMISTRY.

E. G. R. ARDAGH.

**A process of determining metals by electrodeposition without the use of external electric energy.** M. FRANÇOIS. *Compt. rend.* 167, 725-7(1918).—The method,

based on the formation of a voltaic cell, requires the following app.: (1) a 20 to 25 cc. Pt crucible; (2) a sheet of Ni about 0.5 mm. thick, 60 mm. long, and 12 mm. wide with a 3 mm. notch or "fork" about midway; (3) a pure Zn rod about 5 mm. in diam. and 40 mm. long with notches about 3 mm. from one end to fit in the "fork" in the Ni sheet. This rod is amalgamated at least 24 hrs. before use (to prevent secondary currents due to impurities) and is wrapped with a filter paper which is held in place by thread. The Ni sheet is placed across the Pt crucible and the Zn suspended so as to dip into the soln., but not touch the bottom of the crucible; Al may be substituted for the Zn. F. has applied the method to the detn. of Au, Ag and Hg. To det. Au or Ag, place in the crucible 2 cc.  $H_2O$  (to dissolve the Au or Ag salt), 9 cc. of 10% KCN soln., 5 cc. of KOH soln. ( $36^\circ$  Bé.), and 2 cc. of  $NH_4OH$  ( $22^\circ$  Bé.); for the Hg detn. the crucible contains 20 cc. of 10%  $H_2SO_4$  and 0.5 g. of KI. In each case the operation required 24 hrs. F. states that exact results are obtained, but gives no data. In detg. Ag the av. intensity of the current during the first 45 min. of the operation is 7 milliamp., the current density on the crucible is 23 milliamp. per square decm.; with Hg the figures are 33 and 110.

F. W. SMITHER.

**Sampling.** F. W. BUNYAN. *Mining Sci. Press* 117, 827-32 (1918).—The relation is shown between efficient sampling of raw materials and the chem. control of their manuf., and also the necessity for the producer to use representative means of sampling to obtain the value on which to base the sale of his product so that, when the purchaser takes fresh samples, in an efficient manner, there will be no wider discrepancy in results. Cases are cited of "grab sampling" and of sampling from chutes, cars and elevators and it is shown wherein the human element, intentionally or otherwise, plays a large part in making the samples unreliable. The difficulty of obtaining representative samples from material containing a considerable quantity of "fines," is overcome by the use of mechanical samplers wherever possible and when sampling cars or piles, portions are taken from all over in such a way that the material at the bottom of the car or pile is obtained as well as that at the top and the total sample equals 3 or 4% of the bulk.

J. E. CLARK.

**The importance of particle-size reduction before sampling for assay.** A. W. ALLEN. *Eng. Mining J.* 106, 1103-5 (1918).—The necessity is emphasized of reducing the size of particles in ore feeds or mine runs to such a size that the values are more evenly distributed and samples for assay, taken from two or more parts of the feed, will give concordant results, instead of taking the usual head and tail samples of the coarse material and calcg. the complementary figure required to give a metal recovery estn. Samples taken from residues or tailings are usually reliable as the material is finely ground and intimately mixed during mechanical reduction and conveyance.

J. E. CLARK.

**Quantitative separation of iron from the cerite metals in the presence of calcium.** A. WÖBER. *Z. landw. Versuchsw.* 20, 500-1; *J. Chem. Soc.* 114, II, 243.—After soln. by prolonged treatment in 2% HCl, tartaric acid in proportion of approx. 4 g. to 1 is added to an aliquot; Fe is pptd. by satg. with  $H_2S$  and then adding  $NH_4OH$ ; hydroxides of the cerite metals are redissolved. The  $FeS$  is treated in the usual manner, and the cerite metals are detd. by the method of Hauser and Wirth.

R. B. DEEMER.

**A note on the precipitation of zirconium phosphate.** G. STRIGER. *J. Wash. Acad. Sci.* 8, 637-9 (1918).—A note on work done to det. the conditions necessary when applying this method to the analysis of rocks. As the main object of this pptn. was the sepn. of Zr from Ti, Fe, and other metals in a rock, no effort was made to det. the conditions under which Zr phosphate of const. compn. may be pptd. In detg. amts. of Zr so small as those found in the av. rock the analyst can obtain results that are suffi-

ciently accurate by assuming that the compn. of the ignited phosphate is  $\text{ZrP}_2\text{O}_7$  ( $= 46.32\% \text{ ZrO}_2$ ). S. states that "it is not safe to base definite conclusions on the results of work involving quantities so small as those used in these expts., but those results indicate the formation of a basic salt that approaches normal Zr phosphate as the acidity of the soln. is increased." Results reported (in a table) indicate that the soln. used may safely contain at least 3% and perhaps as much as 5% of free  $\text{H}_2\text{SO}_4$ .

F. W. SMITHER.

The uses of cinchonine in the assay of tungsten minerals. H. W. HUTCHIN. *Bull. Inst. Mining Met.* 164, 14 pp.(1918).—A review and discussion of the  $\text{HgNO}_3$  and cinchonine methods, followed by an exptl. study. The scope of the paper is restricted to the assay of the poorer Cornish products. From expts. with synthetic mixts. to det. the effects of vol., acidity, temp., Fe, P, As, and varying amts. of  $\text{WO}_3$ , H. concludes that the best conditions for the pptn. of cinchonine tungstate from solns. of alkali bases are (1) a minimum of acidity, (2) a vol. of 100 cc. to 200 cc., (3) warm soln., (4) standing overnight preferably. The ppt. should be washed with a weak soln. of cinchonine-HCl; Mo is pptd. under similar conditions. The considerable solvent effect of Fe under the synthetic conditions was contrary to the experience with actual assay liquors. The polymerization of  $\text{WO}_3$  in acid solns. under the conditions of an assay explains the different behavior under slightly different conditions. The pptn. of  $\text{WO}_3$  from the Fe liquors of an acid attack is rarely complete. H. outlines methods based on the use of cinchonine: (1) Acid attack; ores and tailings (under 1%  $\text{WO}_3$ ); (2) acid attack; intermediate concentrates, calcined or uncalcined. (3)  $\text{NaOH}$  (25%) digestion attack; ores, tailings, uncalcined intermediate products. (4)  $\text{Na}_2\text{O}_2$  fusion method completing the detn. by the cinchonine or  $\text{HgNO}_3$  methods. Where a preliminary evapn. with HF has been made, the fusion with  $\text{Na}_2\text{O}_2$  will result in the presence of considerable amts. of sol. fluoride in the Na tungstate solns. In such circumstances the  $\text{HgNO}_3$  method is better. H. recommends the following method as an alternative to fusion with  $\text{Na}_2\text{O}_2$ , a very good method for calcined Cornish intermediate concentrates irrespective of the type of calciner: Mix 1 g. with 2 to 3 g. of  $\text{CaCO}_3$  and transfer to an alundum crucible lined with  $\text{CaCO}_3$ ; ignite in a hot Sn furnace for 15 min., let cool, place in a 4-in. porcelain dish, slake with a little  $\text{H}_2\text{O}$ , cover, and add 20 cc. concd. HCl. When action ceases, wash off the cover glass, add 5 cc. of 5% cinchonine solns., and evap. to dryness or until just pasty. Add 2 cc. HCl and about 20 cc. of  $\text{H}_2\text{O}$ , warm on  $\text{H}_2\text{O}$  bath, let stand till cold, then filter through ordinary paper and wash with weak cinchonine soln. Transfer the ppt. from the paper to a beaker, rinse the dish with warm dil. NaOH soln. and pour over the paper, finally washing with small portions of  $\text{H}_2\text{O}$ . Add a little more dil. NaOH soln. to the beaker, boil, add  $\text{NH}_4\text{NO}_3$ , etc., as for  $\text{HgNO}_3$  pptn. For the assay of poorer products, with more pronounced impurities of As and  $\text{CaF}_2$ , cinchonine is invaluable; As and P cease to be disturbing factors. Other methods such as ignition with CaO, or CaO and  $\text{NH}_4\text{Cl}$  followed by an acid attack, become distinctly sound methods when cinchonine is used. The choice of methods will depend upon the nature of the product (material ranging from 0.65% to 70%  $\text{WO}_3$ ). Whatever the final choice of method, it is essential to save the  $\text{WO}_3$ , and when several hundred mg. have accumulated to det. its purity. Aq. HF attacks both scheelite and wolfram in fine powder, the former about 95%, the latter about 30%. It is not advisable to acidify the residue from HF evapn. with acid and filter, since a serious loss of W may occur through soly. The fusion methods are attended with difficulties when considerable amts. of arsenical mineral and other sulfides are present. A preliminary calcination is the safest procedure. The most suitable methods where scheelite is present are those based on acid attack or fusion with alkalis, the least suitable are the methods based on digestion with caustic alkali.

The one essential to success with the digestion methods is sufficiently fine powdering of the sample; KOH is better than NaOH. The results obtained by the different methods on various products are reported and discussed at some length. F. W. SMITHER.

**The wet assay of low-grade tin ores.** H. W. HUTCHIN. *Bull. Inst. Mining Met.* 164, 6 pp.(1918).—A comparative study reported in detail, of the CaO, Beringer, and Pearce methods as applied to Cornish ores. Preliminary expts. with  $\text{SnCl}_4$  soln. showed that Sn ores can be evapd. with HF in the presence of HCl and  $\text{NH}_4\text{Cl}$  without loss of  $\text{SnCl}_4$  by volatilization. H. concludes that while good work can be obtained with any of the 3 methods, the Beringer assay is the most suitable from many points of view. For exact work and as a precautionary measure the retreatment of residues is necessary.

F. W. SMITHER.

**The quantitative determination of gold, especially in animal tissue.** SIDNEY M. CADWELL AND GLADYS LEAVELL. *J. Am. Chem. Soc.* 41, 1-12(1919).—Method and results are given whereby Au is detd. very accurately (electrolytically) in solns. of animal tissues even if Cu and Fe are present. Concns. must be low—about 1 in 20,000.

ERLE M. BILLINGS.

**Sampling and analysis of chromite.** A. A. HANKS. *Mining Sci. Press* 117, 654-5(1918).—Representative samples 40-60 lbs. should be crushed to  $\frac{1}{2}$  in., quartered 10-12 lbs., rolled to 12-16 mesh, and then cut down to 1 lb. The whole lb. should be pulverized in a disk grinder or other machine to 100-150 mesh, and dried to const. wt. at  $100^\circ$ . The standard method of analysis is described in text-books of Low, Scott and Blasdale. The following rapid method is in use at the Berkeley Expt. Sta., U. S. Bureau of Mines: Weigh 0.5 g. 100-mesh sample, brush into a 20-cc. spun iron crucible contg. 4-5 g.  $\text{Na}_2\text{O}_2$  (tech.). Mix well with a glass rod, cover with a little  $\text{Na}_2\text{O}_2$ , fuse at a low red heat, and keep molten for 5 min. Allow to cool, place in a 600-cc. beaker (low expansion glass) or large casserole, add  $\text{H}_2\text{O}$ , digest until the fused mass is disintegrated; then remove and rinse the crucible, boil 10 min. to decompose  $\text{Na}_2\text{O}_2$  (this saves time and there is no interference unless Mn is present). Without filtering, neutralize the soln. with 1:4  $\text{H}_2\text{SO}_4$  or 1:1 HCl and add 25-30 cc. in excess. Dil. to approx. 400 cc., cool and titrate with standard  $\text{FeSO}_4$  (about 0.2 N; 56-60 g.  $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$  in 800 cc.  $\text{H}_2\text{O}$ , 100 cc.  $\text{H}_2\text{SO}_4$ , cool, dil. to 1000 cc.). Add a slight excess of  $\text{FeSO}_4$  soln. as shown by spot plate tests with  $\text{K}_3\text{Fe}(\text{CN})_6$  and finish by titrating back with 0.2 N  $\text{K}_2\text{Cr}_2\text{O}_7$  soln. (9.806 g. c. p.  $\text{K}_2\text{Cr}_2\text{O}_7$  per l.). The  $\text{FeSO}_4$  soln. may be standardized against the  $\text{K}_2\text{Cr}_2\text{O}_7$  soln., or a  $\text{KMnO}_4$  soln. based on Bureau of Standards  $\text{Na}_2\text{C}_2\text{O}_4$ .

H. M. LANCASTER.

**A rapid method for determining titanium and chromium in beach sand.** E. P. BARRETT. *Mining Sci. Press* 117, 729-30(1918).—Weigh 0.5-1 g. 150-mesh ore into a porcelain crucible containing 6-8 g.  $\text{Na}_2\text{O}_2$ , mix and fuse over a Meker burner, holding the crucible in the tongs so as to rotate the contents after fusion begins. Heat slowly at first. If a perfect fusion is not obtained in 5 min., cool, add a little more  $\text{Na}_2\text{O}_2$  and heat again. Place the crucible in a 600-cc. beaker contg. about 400 cc.  $\text{H}_2\text{O}$ , place on a hot plate and boil for at least 15 min. Cool in a tray of running water (10 min. sufficient), filter and wash with dil. NaOH. The residue contains all the Ti and Fe; the filtrate contains Cr and may be used for its detn. Wash the residue through the filter with hot 10%  $\text{H}_2\text{SO}_4$ , wash well with hot  $\text{H}_2\text{O}$ , add 10 cc. HCl, the total vol. of the soln. being now about 100 cc. Proceed with the Shimer method (8th Internat. Congr. App. Chem.) as modified by Scott (text-book—Stand. Methods Chem. Anal.). The method may also be used to det.  $\text{Cr}_2\text{O}_3$  in chromite. Such an assay may be made in about 1 hr. If only  $\text{Cr}_2\text{O}_3$  is to be detd. use an iron crucible for the fusion.

H. M. LANCASTER.

**Sulfur dioxide method for determining copper minerals in partly oxidized ores.** C. E. BARNEVELD AND EDMUND S. LEAVER. *Bur. Mines, Tech. Paper* 198, 12 pp. (1918).—See *C. A.* 12, 1032. E. H.

**Potassium determination by perchloric acid.** GENESSEE CHEMICAL CO. *Chem. Analyst* 26, (1918).—Producers of potash, consumers of potash (mfrs. of glass, explosives, fertilizers, matches, dyes) as well as research and teaching institutions have adopted the perchloric acid method. There is considerable economy—3 cents worth of  $\text{HClO}_4$  replacing \$8.00 worth of  $\text{PtCl}_4$ . The Scholl method gives 0.1–0.5% accuracy, depending upon the sample. The manipulations are simple and time required is short. H. M. LANCASTER.

**A study of sources of error incident to the Lindo-Gladding method for determining potash.** T. E. KEITR AND H. E. SHIVER. South Carolina Exp. Station, Clemson College, S. C. *J. Ind. Eng. Chem.* 10, 994–6 (1918).—Although there is a plus error arising from the fact that the vol. of soln. is decreased by the bulk of ppt. formed on addition of  $\text{NH}_4\text{OH}$  and  $(\text{NH}_4)_2\text{C}_2\text{O}_4$ , it is partially compensated by the occlusion of potash by the heavy gelatinous ppt. This occluded potash cannot be washed out with hot  $\text{H}_2\text{O}$ , but may be sepd. to a certain extent by repeatedly dissolving the ppt. in  $\text{HCl}$ , dilg. to a large vol., pptg. with  $\text{NH}_4\text{OH}$  and  $(\text{NH}_4)_2\text{C}_2\text{O}_4$ , filtering and detg. K in the filtrates and washings. Studies of standard solns. of pure salts show that when phosphates of Ca or of Fe are pptd. by  $\text{NH}_4\text{OH}$ , there is occlusion of K. The tendency to occlusion is greater if both Ca and Fe phosphates are present. H. M. LANCASTER.

**Gravimetric analysis. VI. Calcium.** L. W. WINKLER. *Z. angew. Chem.* 31, I, 187–8, 203 (1918); cf. *C. A.* 12, 1177.—(1) *Detn. as Ca oxalate*: To obtain a granular ppt., the soln. must be boiling hot, acid with  $\text{AcOH}$ , and contain considerable  $\text{NH}_4\text{Cl}$ . To the neutral soln., 100 cc. in vol., containing max. 0.1 g. Ca, add 3.0 g.  $\text{NH}_4\text{Cl}$  and 10 cc. *N* acetic acid. Heat to boiling, add dropwise 20 cc. of 2.5%  $(\text{NH}_4)_2\text{C}_2\text{O}_4$  soln. and boil gently about 5 min. For very accurate work the soln. should stand a day before filtering. Filter, wash with 50 cc. cold  $\text{H}_2\text{O}$ , dry at  $100^\circ$  and weigh as  $\text{CaC}_2\text{O}_4 \cdot \text{H}_2\text{O}$ . A table of corrections is given for use when very accurate detns. are desired. When sulfates are present, the ppt. contains important quantities of  $\text{CaSO}_4$ , but the mol. wt. of  $\text{CaSO}_4 \cdot \frac{1}{2}\text{H}_2\text{O}$  being nearly the same as that of  $\text{CaC}_2\text{O}_4 \cdot \text{H}_2\text{O}$ , an appreciable error is avoided. The presence of  $\text{NH}_4\text{NO}_3$ ,  $\text{KCl}$ ,  $\text{NaCl}$ ,  $\text{CrO}_3$ ,  $\text{KNO}_3$  or  $\text{KClO}_3$  does not cause error.  $\text{NaOAc}$  causes slightly high results. The influence of Mg will be given in another communication. (2) *Detn. as CaO*: Ppt. as oxalate as above. Let stand till next day, filter and wash with 50 cc. hot water containing  $(\text{NH}_4)_2\text{C}_2\text{O}_4$ . Ignite ppt. and filter moist in a Pt-crucible to  $\text{CaO}$ . The error resulting from traces of  $\text{CaCO}_3$  remaining is compensated by the traces of  $\text{CaC}_2\text{O}_4$  remaining in the soln. Expts. show that cryst.  $\text{CaCO}_3$  (Iceland spar) cannot be transformed into pure  $\text{CaO}$  by blasting several hrs. 56.11–56.13% were found for the residue instead of the calcd. value 56.025%. The presence of sulfates causes high results. (3) *Detn. as  $\text{CaCO}_3$* : While for the detn. of Ba and Sr as carbonate, an addition of  $\text{KNO}_3$  is necessary in order to obtain a granular ppt. from a  $\text{CaCl}_2$  soln. a granular ppt. can be obtained, without addition of  $\text{KNO}_3$ . Heat to boiling the neutral soln. (100 cc. containing not more than 0.1 g. Ca and free from  $\text{NH}_4$  salts) and ppt. with 10 cc. 10%  $\text{Na}_2\text{CO}_3$  soln. Boil for several min., filter next day, wash with 50 cc. water free from  $\text{CO}_2$  and satd. with  $\text{CaCO}_3$ , or with 50 cc. water which containing 1 cc.  $\text{NH}_4\text{OH}$  and some  $(\text{NH}_4)_2\text{CO}_3$  soln., dry at  $132^\circ$ . The following points must be observed: (a)  $\text{NH}_4\text{Cl}$  hinders a complete pptn. of  $\text{CaCO}_3$ . (b) In the presence of  $\text{NH}_4$  salts, a mixt. of  $\text{NaOH}$  and  $\text{Na}_2\text{CO}_3$  solns. is to be used as precipitant and the soln. must be boiled till all  $\text{NH}_3$  is expelled:  $\text{KCl}$ ,  $\text{NaCl}$ ,  $\text{KNO}_3$ ,  $\text{KClO}_3$ ,  $\text{NaC}_2\text{H}_3\text{O}_2$  hardly

influence the results. (c) In the presence of chromic acid the ppt. contains a little of it. Conclusion: The best method for detg. Ca is as oxalate. TH. VERHEGGEN.

**Determination of calcium and magnesium in different saline media.** E. CANALS. *Bull. soc. chim.* 23, 422-30(1918).—An exptl. study reported in detail. In the work reported, 0.1 g. of pure pptd.  $\text{CaCO}_3$  was treated with 15-30 cc.  $\text{H}_2\text{O}$  and sufficient  $\text{HCl}$  to effect soln. The  $\text{CaSO}_4$  method yields exact results by using 2 vols. of 80% alc., avoiding a large excess of  $\text{H}_2\text{SO}_4$ , letting stand 6 hrs., and igniting at a dull red for 5 min. To det. Ca as  $\text{CaCO}_3$ , add 10 cc.  $\text{NH}_4\text{OH}$  and 5 cc. of 10%  $(\text{NH}_4)_2\text{CO}_3$  soln.; let stand 12 hrs. at about  $30^\circ$ , filter, wash with ammoniacal  $\text{H}_2\text{O}$ , dry; ash paper separately and carbonate the ash, finally ignite ppt. and ash at a very dull red for 1 min. Ignition (5 min. at bright red) to  $\text{CaO}$  requires less care and is preferable. To det. Ca as  $\text{CaC}_2\text{O}_4$ , add 10%  $(\text{CO}_2\text{H})_2$  soln. to the boiling acid soln., followed by  $\text{NH}_4\text{OH}$  in slight excess, added dropwise; boil until odor of  $\text{NH}_4\text{OH}$  can no longer be noted, filter hot, and wash with hot  $\text{H}_2\text{O}$ , avoiding an excess. Dry, ignite paper separately and carbonate the ash; ignite ppt. and ash at a very dull red for 5 to 7 min., finally weighing as  $\text{CaCO}_3$ ; or, ignite for 10 min. at a bright red and weigh as  $\text{CaO}$ . C. concludes that the oxalate method (weighing as  $\text{CaCO}_3$  or  $\text{CaO}$ ) is the best, although the other, under the conditions stated, yields exact results. The work is being continued. Cf. Blanchetière, *Bull. soc. chim.* 19, 8(1916). F. W. SMITHER.

**Determination of oxygen in steel.** P. OBERHOFFER. *Stahl u. Eisen*, Feb. 7, 1918; *Iron Age* 102, 1573(1918).—A modification of the Ledebur method. The app. consists of: (1) An electrolytic H generator (a large U-tube containing Ni gauze electrodes and  $\text{KOH}$  soln.); (2) the purification train for the H ( $\text{P}_2\text{O}_5$ -tube, heated quartz spiral containing Pt gauze,  $\text{P}_2\text{O}_5$ -tube); (3) a "Beutell" Hg exhaustion pump; (4) a quartz combustion tube and weighed  $\text{P}_2\text{O}_5$ -U-tube; (5) electric resistance furnace arranged on a guiding rail so that it can be slipped into place when needed. All of the connections are of glass. Nos. 1, 2 and 3 are arranged on a vertical board, and Nos. 4 and 5 on a shelf permanently attached to the board. The temp. is measured by a thermocouple inside the resistance furnace and near the quartz tube; 20 min. at  $950^\circ$  in an atm. of H suffices for a 10 g. sample. A detn. requires about 1 hr. The author gives a table of results of O detns. on basic Bessemer steel, before and after deoxidation, and describes (in the original) how microsections can be subjected to the influence of the H when investigating non-metallic inclusions. F. W. SMITHER.

**Results of further coöperative work on the determination of sulfur in pyrite check sample No. 4.** H. C. MOORE. *J. Ind. Eng. Chem.* 11, 45-9(1919).—A continuation of work previously reported (cf. C. A. 9, 2203; 11, 240). The results obtained in 39 different labs. indicate that the conclusions arrived at for the work of previous years apply equally to that of the past year. F. W. SMITHER.

**Detection and determination of phosphine in hydrogen.** J. SOYER. *Ann. chim. anal.* 23, 221-5(1918).—S. recommends the following methods for the technical examn. of H prepd. from Fe-Si and  $\text{NaOH}$ : *Detection*: After bubbling the H through  $\text{H}_2\text{O}$  contained in a Cloez wash bottle, pass through a plug of glass wool to remove excess  $\text{H}_2\text{O}$ , and then through a glass tube with a Pt tip; ignite, and bring a porcelain cover over the flame; a green coloration indicates  $\text{PH}_3$ . *Spectroscopic examn.* of this chilled flame shows clearly the 3 P lines. On introducing a drop of  $\text{H}_2\text{O}$  (suspended in a loop of wire) into the flame for about  $1/15$  of a sec., sufficient  $\text{H}_3\text{PO}_4$  is obtained to give a yellow ppt. with molybdate reagent. *Determination*: The app. consists of a graduated bell jar (2 to 5 l. capacity) provided with a stopper carrying a T-tube with 2 stopcocks to establish communication with the H reservoir and with the combustion tube. The latter is of quartz (or porcelain), about 40 cm. long, and slightly inclined; through a

stopper in the forward end passes the tube (with a Pt tip) for admitting H from the bell jar. The rear end of the tube is closed by a rubber stopper carrying a glass tube connected with 2 Cloez wash bottles, the latter being connected with a filter pump. The forward portion of the tube is heated to bright redness by means of a bunsen; the posterior end is cooled by means of a cloth mantle over which  $H_2O$  falls dropwise. To operate, aspirate by means of the pump, and connect the bell jar (previously filled with H) with the combustion tube. The H ignites in contact with the hot walls of the tube, the  $PH_3$  being quant. transformed into  $H_3PO_4$ . At the end of the combustion, aspirate a min. or so, transfer to a porcelain dish the condensate in the combustion tube and the solns. in the wash bottles, washing these and the H delivery tube with warm  $H_2O$ . Add 5 g.  $NH_4NO_3$ , evap. to about 40 cc., transfer to a 150-cc. beaker, cool to  $50^\circ$ , add 100 cc. of molybdate soln., and let stand, with frequent stirring, for 2 hrs. at  $40^\circ$ . Filter on tared filters, wash with molybdate soln., then with cold  $H_2O$ , and dry to const. wt. at  $60-70^\circ$ . Wt. of phosphomolybdate  $\times 0.01789$  = wt. of  $PH_3$  contained in the vol. of gas analyzed. Taking the d. of  $PH_3$  as 1.214, then the wt. in g. of the phosphomolybdate  $\times 11.395$  = no. of cc. of  $PH_3$  contained in the vol. of gas examd.  $87.7578 +$  wt. of phosphomolybdate corresponding to 1 l. of the gas = vols. of H containing 1 vol. of  $PH_3$ . Notes: Operating on 100 l. of H a millionth vol. of  $PH_3$  can be detd. gravimetrically by this method; smaller concns. can be detd. colorimetrically. The vol. of air aspirated should always be in excess of that required for the H burned. The optimum amt. of gas to burn depends upon the  $PH_3$  content, e. g., 2 l. for a diln. of  $1/1000$  in vol., 5 l. for  $1/10000$ , 20 l. for  $1/100000$ . With a Pt tube of 1.5 mm. inside diam., 20 l. of H can be burned in less than 1 hr. The method can be rendered more exact by measuring the gas over Hg instead of  $H_2O$ .

F. W. SMITHER.

Copper sulfate as an indicator for alkalinity in nitrogen distillation. J. H. ROOP. *Chem. Analyst* 26, 8(1918).—When beginning the Kjeldahl digestion with  $H_2SO_4$  and  $Na_2SO_4$  or  $K_2SO_4$ , add 0.2 g. powdered  $CuSO_4$ . The clear soln. will turn blue when alkali has been added in quantity sufficient to liberate the  $NH_3$  for distn.

H. M. LANCASTER.

Some methods for the quantitative determination of nitrite and nitrate in presence of one another. ALICE OELSNER. *Z. angew. Chem.* 31, I, 170-2, 178-9(1918).—For bacteriological analysis one should have at one's disposal several methods for estg. nitrites and nitrates. The usual methods are: (A) Colorimetric methods of Tillner and Sutthoff, and of Letts and Rea; (B) Gasvolumetric methods of P. Gerlinger, Pellet, de Koninck, Boullanger and Massol, Meisenheimer and Heim, Winogradsky; (C) a method deduced from these by Oelsner; (D) precipitation methods of Busch, F. Hahn; (E) Ester method of Fischer and Steinbach. Oelsner's method is analogous to that of Winogradsky but has the advantage of not requiring a gas analysis. The soln. containing nitrite and nitrate is first titrated according to Lunge with  $KMnO_4$  in sulfuric acid soln. Because of the volatility of nitrous acid, the titration is made by running the soln. of nitrite, from a buret, into a measured quantity of  $KMnO_4$  (0.02 N) soln. acid with  $H_2SO_4$ , diluted with water and heated at  $40^\circ$ . The last drops must be added slowly because the change of red into colorless always requires a little time. After decoloration, it is best to titrate back with  $KMnO_4$  soln. The nitrate produced is detd. by reducing to  $NH_3$  by Zn and Fe in alk. soln. The nitrate is detd. by difference. For the nitrate detn. it is necessary according to Seydel and Wichers [*Z. angew. Chem.* 24, 2046(1911)] to use 10-30 mg. nitrate-N for the assay; less than 10 mg. gives too much nitrate, more than 30 mg. too little. Hence more soln. is required for the nitrate than for the nitrite detn. Detns. made by this method upon  $NaNO_3$  soln. containing 28 mg. N in 100 cc. show that the results obtained by oxidation of the nitrite (27.3 mg. N), by reduction of the nitrate (28.5 mg. N) are sufficiently concordant with the

calcd. amt. of N (28 mg. N). Detns. made upon a soln. containing in 100 cc. 138 mg.  $\text{NaNO}_2$  = 28 mg. nitrite-N and 170 mg.  $\text{NaNO}_3$  = 28 mg. nitrate-N, show that the error in the detn. of the nitrite, or of the nitrate, is smaller than 1 mg. (calcd. for 100 cc. soln.). The error for the total-N detn. is a little higher, 1.3 mg. in one case. The weighed N quantities are found again up to 1.2 mg. for 100 cc. soln., thus 0.002%. This method is well adapted for following quant. the nitrification process, provided  $\text{FeSO}_4$  is absent. O. finds the influence of the presence of citric acid in the nitrite detn. to be very slight provided the addition of nitrite towards the end is very slow and the back titration is omitted.

TH. VERHEGGEN.

**Arsenite titrations of permanganate solutions.** ALOKE BOSE. *Chem. News* 117, 369-70(1918).—When permanganic acid, formed in steel solns. with  $\text{HNO}_3$ , is titrated with a standard soln. of  $\text{Na}_2\text{AsO}_3$  it is found that the factor obtained for Mn is about 1.5 times as much as the theoretical factor. It has been suggested that this is due to the reducing action of  $\text{HNO}_3$  either on the permanganate or arsenite, to the formation of manganic compds., or to the formation of a definite compd. either in the permanganate or arsenite. B. cites numerous expts. to prove that the cause is not attributable to any one of the three. Some other explanation is to be sought.

ERLE M. BILLINGS.

**Free acid determination in presence of metallic salts.** LOUIS F. CLARK. Potrerillos, Chile. *Eng. Mining J.* 106, 1066-8(1918).—Alc. is used to throw the metals out of soln. after adding neutral  $(\text{NH}_4)_2\text{SO}_4$  or a mixt. of 3 parts  $(\text{NH}_4)_2\text{SO}_4$  and 1 part anhyd.  $\text{Na}_2\text{SO}_4$  to form double salts with the metals. Cochineal is used as indicator and either alc. or aq. standard  $\text{NaOH}$  is used for titration. For *leach liquors* take 10 cc. sample, add about 4 g.  $(\text{NH}_4)_2\text{SO}_4$  and let stand till dissolved. Add 100 cc. EtOH (34-38° Bé.), agitate and allow to stand 20 min. If ppt. is not yet granular, add more  $(\text{NH}_4)_2\text{SO}_4$ . Add a dash of cochineal (made with 34° Bé. alc.) and agitate well while titrating. The alc. solns. may be filtered before titrating but a blank must be run to est. the loss of acid by mechanical retention in the ppt. Denatured alc. may be used for this work except for making up the standard alc.  $\text{NaOH}$  as the alkali decomposes the denaturant and the liquid becomes badly discolored.

J. E. CLARK.

**The identification of acids of agricultural products.** J. B. RATHER AND E. EMMETT REID. Arkansas Agr. Expt. Sta., *Bull.* 156, pp. 32(1918).—A study of the use of bromoacetophenone as a reagent in prepg. the phenacyl esters of acids both singly and in mixts. The method of prepg. this compd. and the details of prepn. and identification of the following esters are given: acetate, lactate, palmitate, stearate, succinate, glutarate, pyrotartrate, malate, tartrate, saccharate, maleate, fumarate, citraconate, itaconate, citrate, aconitate, benzoate, salicylate, *o*-, *m*-, and *p*-cresotate, mandelate, *o*-aminobenzoate, and cinnamate. The following acids have been sepd. and identified in the presence of each of the acids named: citric acid in the presence of tartaric, malic, benzoic, oxalic, acetic; succinic acid in the presence of tartaric, malic, citric, oxalic, fumaric, acetic, butyric; malic acid in the presence of tartaric, succinic, citric, oxalic, acetic; tartaric acid in the presence of succinic, malic, citric, benzoic, oxalic, acetic; stearic acid in the presence of palmitic, oleic, butyric; palmitic acid in the presence of stearic, oleic, butyric; benzoic acid in the presence of salicylic, acetic, tartaric, citric, oxalic, succinic; fumaric acid in the presence of maleic and succinic; and cinnamic acid in the presence of benzoic.

R. B. DEEMER.

**Determination of aldehyde sugars by means of iodine in alkaline medium.** H. COLIN AND O. LIEVIN. *Bull. soc. chim.* 23, 403-5(1918).—In studying the carbohydrate transformations in plant physiology it is often useful to know the ratio of glucose and fructose. Bougault has proposed a method based upon the fact that aldoses are oxid-

ized by iodine in alkaline solution while ketoses are not. In this method the plant extract is oxidized with iodine and the excess of iodine detd. The authors of this paper tried this method on plants rich in inulin. The results obtained were concordant with those obtained by the usual method of analysis based upon polariscopic readings and the reducing power of the tested soln.

J. K. DALE.

**Volumetric determination of reducing sugars.** A simplification of Scales' method for titrating the reduced copper without removing it from the residual copper solution. W. BLAIR CLARK. *J. Am. Chem. Soc.* 40, 1759-72 (1918).—The exact conditions are worked out and described for detg. reducing sugars volumetrically by a simplification of Scales' Method. A modified Benedict's alkaline copper soln. was used. The oxidation of the reducing sugars was carried out in the usual way; HCl was then added to distinct acidity after which a slight excess and known amt. of iodine soln. was added. The excess of iodine was then detd. by titration with  $\text{Na}_2\text{S}_2\text{O}_3$  using starch soln. as indicator. The difference between the  $\text{Na}_2\text{S}_2\text{O}_3$  used, and the amt. required by a blank test in which water instead of the substance under examn. is used with the copper soln., gives the  $\text{Na}_2\text{S}_2\text{O}_3$  equiv. of the iodine consumed in oxidizing the copper reduced by the sugar. The  $\text{Na}_2\text{S}_2\text{O}_3$  is standardized by a known quantity of invert sugar or dextrose and from this can be calcd. the amt. of invert sugar or dextrose equiv. to 1 cc. of  $\text{Na}_2\text{S}_2\text{O}_3$  and this factor can be used in calcg. results in unknown solns. The ratio of copper reduced in the citrate-carbonate soln. and hence also of the thiosulfate equiv. of the copper is very nearly proportional to the reducing sugar present. The effect of the time of heating upon the copper reduced is quite marked. Sucrose, alc., and the Crapek-Dox nutritive fluid have no appreciable reducing action on the copper-citrate carbonate soln., but 10% HCHO effects a small reduction.

J. K. DALE.

**New reaction for acetylcarbinol.** OSKAR BAUDISCH. *Biochem. Z.* 89, 279-80 (1918); *J. Chem. Soc.* 114, II, 412.—A dil. soln. of acetylcarbinol in  $\text{H}_2\text{O}$  containing NaOH is boiled for a few min. with  $o\text{-H}_2\text{NC}_6\text{H}_4\text{CHO}$ . The mixt. is then cooled, acidified, and made alk. again with  $\text{NaHCO}_3$ . A fluorescent soln. is obtained, from which 3-hydroxy-2-methylquinoline can be extd. by  $\text{Et}_2\text{O}$ ; on distg. off the  $\text{Et}_2\text{O}$ , it is obtained as a white residue, which gives a deep red color with alc.  $\text{FeCl}_3$ . The alc. soln. also gives a brilliant blue fluorescence on diln. with  $\text{H}_2\text{O}$ . These 2 reactions are characteristic.

C. J. WEST.

**Color reaction of aminoborneol.** J. TAKEEDA AND S. KURODA. *Yakugaku Zasshi (J. Pharm. Soc., Japan)* 441, 847-55 (1918).—Extending the reaction of  $\text{Cu}(\text{OH})_2$  toward amino alcohols to the  $\alpha$ - and  $\beta$ -aminoborneols and their alkyl derivs., the authors have observed that only the  $\beta$ -isomer or cis- form of aminoborneol or its *N*-mono-alkyl deriv. reacts with  $\text{Cu}(\text{OH})_2$  to form a red-violet complex salt of the formula  $(\text{R}'\text{CH}(\text{OH})\text{CH}(\text{NH}_2)\text{R}'')_2\text{CuO}$ . They considered this reaction as the characteristic of the  $\beta$ - or cis- form of amino alcohols.

## 8. MINERALOGICAL AND GEOLOGICAL CHEMISTRY.

EDGAR T. WHERRY AND J. H. BOWER.

**Chubutite, a new lead mineral.** HERCULES CORTI. *Anales soc. quim. Argentina* 6, 65-72 (1918).—This mineral (termed *chubutite* from the region of Chubut (Argentina) where it was observed) is yellow, with reddish tinge (sometimes greenish); the powder is canary yellow. The powdered mineral is practically insol. in  $H_2O$ , but readily sol. in dil.  $HNO_3$ ; it is less readily attacked by  $HCl$  and  $H_2SO_4$ , but dissolves in hot 30%  $KOH$  soln. When heated it turns dark maroon, and melts at a higher temp., giving a greenish residue. Its  $d. = 7.9520$  and hardness 2.5; it is brittle. When heated in  $H$  or illuminating gas it is reduced at a low temp. with formation of globules of  $Pb$ , a thin, brilliant layer of metallic  $Sb$ , and drops of acid  $H_2O$ . When fused on  $C$  it yields a metallic globule, with evolution of acid vapors. No  $Ag$ ,  $Au$  and  $Pt$  nor basic element pptd. by  $(NH_4)_2S$  or by carbonates of  $NH_4$  or alkali metals could be detected. The mineral had the following compn.:  $SiO_2$  0.76%,  $Al_2O_3$  0.12%,  $Fe_2O_3$  0.19%,  $Sb_2O_3$  0.69%,  $PbO$  83.30%,  $PbCl_2$  14.83%,  $As$  traces, undetd. 0.11%. Disregarding  $SiO_2$ ,  $Al_2O_3$ ,  $Fe_2O_3$  and  $Sb_2O_3$ , the formula is  $7PbO.PbCl_2$ . The absence of  $Ag$  may be explained on the supposition that the mineral was originally produced in a slightly reducing medium, and small amts. of metallic  $Pb$ , having a greater  $d.$  than the molten mineral, settled out, removing with it any  $Ag$  originally present. This supposition is supported by fusing in a slightly reducing medium (Perrot furnace) a mixt. of comm. litharge (containing a small amt. of  $Ag$ ) and  $PbCl_2$  in the same proportion found in natural chubutite. A cryst. mass similar to the mineral was obtained; the free  $Pb$  contained all the  $Ag$  originally present, while the oxychloride was entirely free from  $Ag$ . In a slightly oxidizing medium no free  $Pb$  was obtained. Micrographic examn. showed the mineral to be composed of thin laminas of variable transparency, greenish yellow and non-pleochroic; the value of  $n$  was not high, and the birefringence slight. The mineral probably belongs to the tetragonal system.  $C.$  enters into a description of other  $Pb$  minerals which have the same qual. compn. as chubutite and compares them with the latter. Cf. Lorettoite; Wells and Larsen, *C. A.* 11, 131. H. S. PAINE.

**Chemical study of a titanium mineral from the Sierra del Pié de Palo (San Juan).** LUCIANO R. CATALANO. *Anales soc. quim. Argentina* 6, 35-48, 83-93 (1918).—This mineral consists of 3 distinct mineralogical species which may be readily sepd. by color and hardness; 2 of these are talc and calcite, and the 3rd has the following physical properties: metallic or submetallic luster; streak black;  $H. > 6$ ;  $d. = 4.69$ . It can be heated to  $180^\circ$  without apparent change in compn., but at red heat the color changes somewhat and the wt. increases, owing to oxidation. The mineral is anhydrous and also yields no gases when heated. Cold concd.  $HCl$  dissolves it almost completely. Treatment with hot  $HCl$  results in a soln. containing a whitish ppt. insol. in excess of  $HCl$ . Soln. in  $HNO_3$  is slow; aqua regia acts slowly and not as completely as  $HCl$ ;  $H_2SO_4$  only attacks the mineral when hot and then only slowly. Fusion with  $Na_2CO_3$ ,  $NaOH$ , or  $Na_2O_2$  causes complete decompn.; the fused mass is sol. in  $H_2O$  with a reddish residue of  $Fe$  oxide and  $Na$  metatitanate. This residue is sol. in  $HCl$ , leaving a residue of  $Ti$  oxide. Fusion with  $KHSO_4$  or  $NaHSO_4$  causes complete decompn. and yields a mass completely sol. in dil.  $H_2SO_4$ . This aq. soln. is hydrolyzed when heated,  $Ti$  oxide being formed. The mineral was fused with  $PbCO_3$ , the temp. being gradually raised to redness. Tests with the fused mass failed to show the presence of  $SiO_2$ ,  $K$  and  $Na$ . Analysis showed:  $FeO$  45.35,  $TiO_2$  25.40, and  $MnO$  1.84%, corresponding to  $(Fe, Mn)TiO_3$ . The mineral is thus a new variety of ilmenite. H. S. PAINE.

**The probable identity of peganite with variscite.** LORENZO MOSCHETTI. Univ. Torino. *Atti reale accad. sci. Torino* 53, 1062-6 (1917-8).—A cryst. hydrous  $Al$  phosphate

from Saxony was named peganite by Breithaupt in 1830 on the basis of an analysis showing  $\text{Al}_2\text{O}_3$  44.49,  $\text{P}_2\text{O}_5$  31.25, and  $\text{H}_2\text{O}$  22.82, corresponding to  $2\text{Al}_2\text{O}_3 \cdot \text{P}_2\text{O}_5 \cdot 6\text{H}_2\text{O}$ . Crystallographically, in so far as it was measurable, it was identical with wavellite, but it is usually classed by mineralogists as a definite species. In the course of time material from other localities was assigned to the same species, although some from Arkansas was subsequently shown to be variscite, and that from Portugal agrees, as shown by 2 analyses in the literature, much more closely with wavellite than with the original peganite. The  $\text{H}_2\text{O}$  content seems low for wavellite, but this mineral loses over 2% of  $\text{H}_2\text{O}$  below  $100^\circ$ , which may well account for this. A specimen of peganite from the type locality agreeing in properties with that described by Breithaupt, was analyzed, and gave:  $\text{CaO}$  0.65,  $\text{Al}_2\text{O}_3$  31.63,  $\text{Fe}_2\text{O}_3$ ,  $\text{MnO}$  traces,  $\text{P}_2\text{O}_5$  44.99,  $\text{H}_2\text{O}$  23.20. insol. 0.01, sum 100.48%. This corresponds exactly with  $\text{AlPO}_4 \cdot 2\text{H}_2\text{O}$ , which is the formula of variscite [also of lucinite—ABSTR.]. It agrees moreover with variscite in its insol. in b.  $\text{HCl}$ ; and in becoming lilac to bluish lavender on heating to  $120$ – $150^\circ$ ; and in its sp. gr., which is 2.56–2.57, or according to Breithaupt 2.492–2.496, while variscite from Utah has 2.54 and that from Voigtland 2.41. It is suggested that Breithaupt may have got his figures for  $\text{Al}_2\text{O}_3$  and  $\text{P}_2\text{O}_5$  transposed, in which case his analysis would be essentially identical with the present one. And it is concluded that the evidence that peganite exists as a species apart from variscite is inadequate, so the former name should be withdrawn from mineralogic literature. [The question could be more satisfactorily settled had Breithaupt or M. furnished even the simplest optical data.—ABSTR.] E. T. W.

**Factors influencing gold deposition in the Bendigo Goldfield.** F. L. STILLWELL. *Bull. Commonwealth of Australia, Advisory Council of Sci. and Ind.* 1917, No. 4, 68 pp. —A more detailed account of the region previously described (C. A. 12, 1277).

S. G. GORDON.

**The alunite deposits of Australia and their utilization.** FRANK W. JAMES. *Bull. Commonwealth Australia, Advisory Council Sci. and Ind.* 1917, No. 3, 38 pp.—Alunite occurs at Carricklinga, S. Australia, as nodular masses in decomposed slate or pug, lying in a continuous vein along the bedding planes of the slate; at Warnertown, S. Aus.; and at Bullahdelah, N. S. W., where the high grade ore occurs only in patches or enrichments in a main body of low-grade alunite. The ore produced has been shipped to England for the production of alum and Al sulfate. Heat treatment showed that: at  $500^\circ$  the alunite loses its  $\text{H}_2\text{O}$  of constitution and is converted into K-Al-sulfate and alumina; at  $600^\circ$  a slight decompn. of the former takes place; at  $700^\circ$ ,  $\text{SO}_2$  is freely evolved; at  $800^\circ$  the decompn. is rapid and complete, the action being finished in an hour. The expts. showed the necessity of thorough rabbling and quick removal of the  $\text{SO}_2$  to effect a speedy and thorough roast on a large scale. The  $\text{SO}_2$  is partly dissociated into  $\text{SO}_2$  and  $\text{O}_2$ , and if it is desired to recover the  $\text{SO}_2$  as sulfuric acid, a muffle type furnace for calcination and a complete sulfuric acid plant would be necessary. A number of expts. for the treatment of alunite to produce  $\text{K}_2\text{SO}_4$  were made, and the following steps are recommended: Crush the ore to about  $\frac{1}{4}$  inch mesh; roast in a suitable furnace alone, or preferably with molasses or sawdust till all sol. alumina is absent; grind roasted ore to pass 40-mesh sieve; treat the residue with boiling water and digest; filter-press the pulp and wash with hot water; evap. the soln. to obtain the  $\text{K}_2\text{SO}_4$ . Notes are given for a working plant, and cost of treatment. Detailed results of exptl. work, analyses, a bibliography, and patent specifications are given.

**An interpretation of the so-called paraffin dirt of the Gulf Coast fields.** ALBERT D. BROKAW. *Bull. Am. Inst. Mining Eng.* 1918, 1674–7; 1919, 98–101; cf. C. A. 12, 1035, 1960.—Discussion of a paper on the above subject. J. H. B.

**A form of multiple rock diagrams.** FRANK F. GROUT. *J. Geology* 26, 622-5 (1918).—Instead of using the chem. analysis directly, which gives a conspicuous line for  $\text{SiO}_2$ , the analyses are recalcd. to norms, in which a larger number of constituents are present. The mode may be substituted for the norm if preferred. These diagrams are clamped into position, permitting rearrangement as they are studied from different points of view.

WALTER F. HUNT.

**A type of igneous differentiation.** FRANK F. GROUT. *J. Geology* 26, 626-58 (1918).—The rocks of the Duluth gabbro fall into two series, one related to the gabbro family, the other to the granite family. Intermediate types are rare. The rocks of the gabbro series are normal gabbro, olivine gabbro, troctolite, peridotite, magnetite gabbro and anorthosite. The line of contact between the gabbro and granite is sharp and without alternation, indicating that the processes involved in the sepn. of granite and gabbro were probably of a different type than those which produced the various phases in the gabbro itself. The various modifications of the gabbro series probably resulted from a differentiation by crystn. during convection, aided by sinking of the crystals. Before solidification was complete the granitic magma sepd. from the gabbro by some other process, and both field and lab. studies suggest a sepn. of an immiscible liquid. Thus evidence is at hand that differentiation of two types may occur in the same magma chamber.

WALTER F. HUNT.

**Titanium-bearing corundum spinellite (rock emery).** THOMAS L. WATSON AND GEORGE STEIGER. *J. Wash. Acad. Sci.* 8, 665-76 (1918).—Vein-like masses or lenses of rock emery up to 6 feet across occur in granite aplite-pegmatite and mica schist near Whittles, Pittsylvania Co., Va., in a region of cryst. rocks. The ore bodies are genetically related to the granite aplite-pegmatite, bodies in the schist occurring near the schist-granite contact and conforming closely with the lamination of the schists. Marked contact effects are shown in places in the schist, with the development of sillimanite, spinel, magnetite, and corundum. The rock emery is a heavy, black, tough, fine-grained cryst. aggregate, somewhat magnetic from the presence of magnetite. Rarely corundum crystals measuring sometimes  $2.5 \times 1$  cm. are developed in the schist. Microscopic study of the ore shows it to consist of green, or sometimes brown, spinel (pleonaste), magnetite, and corundum, with some ilmenite, and an unknown weathering product, a nonpleochroic, isotropic, reddish brown mineral, occurring as distinct rims around the spinel. An analysis of the granite aplite-pegmatite is given. Analysis of spinel by S. gave:  $\text{Al}_2\text{O}_3$  53.52,  $\text{Fe}_2\text{O}_3$  10.35,  $\text{FeO}$  24.53,  $\text{MgO}$  10.02,  $\text{SiO}_2$  0.92,  $\text{TiO}_2$  0.67, sum 100.00%. Rock emery, S.:  $\text{SiO}_2$  2.53,  $\text{Al}_2\text{O}_3$  45.38,  $\text{Fe}_2\text{O}_3$  23.33,  $\text{FeO}$  17.90,  $\text{MgO}$  5.71,  $\text{CaO}$  0.06,  $\text{Na}_2\text{O}$  0.20,  $\text{K}_2\text{O}$  none,  $\text{H}_2\text{O} +$  0.33,  $\text{H}_2\text{O} -$  0.99,  $\text{TiO}_2$  3.72,  $\text{ZrO}_2$  none,  $\text{CO}_2$  0.07,  $\text{P}_2\text{O}_5$  none,  $\text{SO}_2$  none, S none,  $\text{Cr}_2\text{O}_3$  0.05,  $\text{NiO}$  0.04,  $\text{MnO}$  0.15,  $\text{BaO}$  none,  $\text{SrO}$  none, sum 100.46%; sp. gr. 4.152 (av. of 5 detns.).

S. G. GORDON.

**Composition of Miocene conglomerates of the French subalpine ranges.** PIERRE TERNIER AND WILFRID KILIAN. *Compt. rend.* 167, 584-8 (1918).—A petrographic study of 36 samples of these conglomerates is given and the findings are discussed with reference to the origin of the formations.

L. W. RIGGS.

**Oölites and spherulites.** WALTER H. BUCHER. *J. Geology* 26, 593-609 (1918).—H. Schade was the first to show experimentally that concretionary bodies are formed when a substance passes from an emulsion colloid to a solid. The spherical shape of the grains is due to the tendency of the droplets to coalesce. If the change leads to the cryst. state the resulting structure is radial (spherulitic) if the substance is pure, but if other substances are pptd. along with it a concentric (oölitic) structure is developed. Confirmatory observations were obtained with Fe chloride. It is believed

that the same principles underlie the formation of most sedimentary oölites, spherulites and concretions, for almost all substances which are known in one of these forms are also known to occur extensively in nature in the colloidal state. A review of the natural oölites emphasizes this relationship.

WALTER F. HUNT.

**Rhythmic banding of manganese dioxide in rhyolite tuff.** W. A. TARR. *J. Geology* 26, 610-7(1918).—A rhyolite tuff near Tucson, Arizona, contains circular or elliptical stains of  $MnO_2$ , reaching a max. size of 30 mm. The amt. of  $MnO_2$  is small (0.82%) and the areas are banded in character. Two suggestions are advanced to explain their formation: The Mn was either derived from the surrounding tuff and aggregated into the banded form, pptn. being due to oxidation; or the  $MnO_2$  was derived from some mineral located at the nucleus and pptd. in successive rings following the mingling of the outwardly moving soln. with one of oxidizing character. The second view is believed to be the more probable.

WALTER F. HUNT.

**The origin and the age of laterite from the standpoint of recent soil research.** E. BLANCK. *Petermanns Mit.* 63, 233(1917); *Biedermanns Zentr.* 47, 197-8(1918).—The deductions of J. Walther (*Petermanns Mit.* 62, 1(1916), *Biedermanns Zentr.* 46, 385(1917)) concerning laterite are criticized. Laterite cannot be considered as having been exclusively formed in previous ages.

ALBERT R. MERZ.

**Origin of serpentine, a historical and comparative study.** W. N. BENSON. Univ. Otago, N. Z. *Am. J. Sci.* 46, 693-729(1918).—The evidence presented with reference to the large ultra basic masses, "supports the view that the chrysotile or antigorite-serpentine of which they are composed is an alteration product of an originally intrusive peridotite, often more or less pyroxenic, and that in some cases at least the hydration was brought about by the agency of waters emanating from the same magma that produced the peridotite, though not generally until a considerable amt. of further differentiation had taken place." The change was, however, completed by the end of one orogenic period of vulcanicity. In short, "much of the serpentinization is performed by water of magmatic origin."

## 9. METALLURGY AND METALLOGRAPHY.

WILLIAM BRADY, WILLIAM T. HALL.

**Colloids and flotation.** F. G. MOSES. U. S. Bur. Mines, *Tech. Paper* 200, 22 pp.(1918).—This paper shows the application of certain facts of colloidal chemistry and physics to practical flotation operations. The subject is discussed under the general captions: sulfides not wetted by  $H_2O$ ; colloids and adsorption; adsorption and equil.; action of colloids; condition of flotation oils; different types of colloids; benefit from removing colloids; effect of size of sulfide particles; possible application of theories in practice. Many practical examples are cited.

F. W. SMITHER.

**Differential flotation of lead and zinc sulfides.** A. DEL MAR. *Mining Sci. Press* 117, 691-3(1918).—A general discussion based on the author's experience. A flow-sheet is given for mixed gravity and flotation treatment. Of the different reagents for the sepn. of galena from blende, and then concentrating the remaining Zn, in the order of their usefulness for sepg. the Pb the author places eucalyptus oil first, particularly with an acid pulp; next cresylic acid; then hardwood creosote; and last pine-tar oils.

F. W. SMITHER.

**The development of galena flotation at the Central Mine, Broken Hill.** R. J. HARVEY. *Bull. Inst. Mining Met.*, No. 170, 17 pp.(1918).—The object of this paper is to trace the steps by which flotation has superseded gravity concn. at the Central Mine. The ore is a complex Ag-Pb-Zn sulfide associated in the main with quartz, rhodonite, rhodocrosite and some garnet sandstone. It contains about 11 oz. Ag, 14% Pb, 15% Zn. Crushing to 40 mesh is necessary to obtain complete freeing of the mineral particles from the matrix and from each other. The exptl. work is described in detail with tables of results, flow sheets, drawings, etc. The latest galena flotation plant, which has ousted the Card tables previously in use, is called "lead cascades." In this plant there are no moving parts and no use of compressed air. It consists of a series of boxes set one above the other, the pulp in descending from box to box passing through nozzles, thereby drawing into itself the air necessary for flotation. The concentrates overflow the lip of each box and the tailings pass on to the next in series. This plant has been a complete success, the recovery of the Pb and Ag being greater than with Card tables. The galena which escapes the Cascades, if fine, is caught by the galena flotation boxes in the Zn plant; if coarse, it is removed from the Zn concentrates by the Wilfley tables in the de-leading plant. About 2 oz. per ton of a mixt. of coal tar and eucalyptus is added to the pulp as flotation medium. Effective recovery: Pb, 85.6%; Ag, 64.4%; Zn, 83.3%; recovery prior to the introduction of galena or "selective" flotation (same sequence): 77.6, 49.2, 85.8%. The substitution of flotation for gravity concn. has meant the discarding of: 20 Card tables, 4 Wilfley tables and 16 Weir-Meredith vanners in the Pb mill and 14 W.-M. vanners in the de-leading plant, with the necessary attendants and maintenance. Screen analyses of jig Pb concentrates, Card table Pb concentrates and Cascade Pb concentrates are appended.

F. W. SMITHER.

**Glew mill test. Elutriation of the crushed products.** S. J. TRUSCOTT. *Bull. Inst. Mining Met.* 164, 6 pp.(1918).—The crushed products examd. were: the battery feed and the final tailing; the tubemill feed and its discharge; and the concentrate sold. The velocities used in making the analyses, together with the approx. sizes of the quartz and cassiterite particles lifted by these velocities, are given in a table. Tables are also given showing the results of the elutriation grading analyses. Grinding reduced 8% of the tube mill to —1200 mesh. With the battery feed the bulk of the Sn is contained in the coarser sizes, the contents regularly decreasing down to the finest material. The intermediate sandy material gave the highest assays. With respect to the tailing analysis, free cassiterite will no longer exist in the coarsest size. The tube mill figures further indicate that the fine material in the tube mill feed, by reason of unavoidable imperfections in classification, is rich, and that cassiterite does not suffer any undue comminution in regrinding. The figures of the concentrate sold show that, in spite of the calcination, more than  $\frac{2}{3}$  is larger than 300 mesh, and close upon 50% is larger than 200 mesh.

F. W. SMITHER.

**Recovery and losses of tin at Glew Mill.** R. A. THOMAS, *et al.* *Bull. Inst. Mining Met.* 164, 11 pp.(1918).—Report of a sub-committee of the "Tin and Tungsten Research Committee" appointed to investigate the methods of Cornish Sn dressing. The methods followed are reported in detail with analytical and other data, flow sheet of the Glew Mill, etc. The loss found by actual expt. was 35.5%, the theoretical calcd. loss being 35.9%. The ore had the following compn.: loss on ignition, 0.17; As, 0.045; Pb, 0.032; Cu, 0.15; SnO<sub>2</sub>, 1.4; Fe<sub>2</sub>O<sub>3</sub>, 5.2; Al<sub>2</sub>O<sub>3</sub>, 33.88; alkalis, 0.9; CaO, 0.4; MgO, 0.12; SiO<sub>2</sub>, 56.0%. The mean result of vanning assays calcd. from the metallic Sn found by chem. analysis gave a recovery of 65.4%.

F. W. SMITHER.

**Effect of heating and heating and quenching Cornish tin ores before crushing.** A. YATES. *Bull. Inst. Mining Met.* 170, 3 pp.(1918).—An exptl. study reported

in detail. All the tests show that the effect of heating, and still more of heating and quenching, is to make the ore much easier to crush, yielding a crushed product with a greater proportion of middle-sized particles, and a smaller proportion of that fine slime from which very little Sn can be recovered. Seven concn. tests were made between raw, heated, and heated and quenched samples of crushed lump ore, on a Wilfley table; of these 6 did not show any improvement in recovery as a result of the heating. The very fine slime, both from raw and from heated ore, proved in all cases to be much poorer than the av. of the whole lot treated. F. W. SMITHER.

**A dry concentration plant in Arkansas.** T. SHIRAS. *Eng. Mining J.* 106, 909-10 (1918).—A detailed description of a dry-concn. plant to be operated as a custom concentrator in the north Arkansas Zn and Pb district. F. W. SMITHER.

**The Utah copper enterprize. VII. Flotation practice.** T. A. RICKARD. *Mining Sci. Press*, 117, 749-53 (1918).—A detailed description of the operations in the Arthur mill of the Utah Copper Co. A four-page drawing of the mill, in plan and section, accompanies the article. **VIII. The leaching plant.** *Ibid* 787-91.—This installment gives a detailed description, with illustrations, drawings, screen analyses, etc., of the plant for treating the oxidized Cu ore (av. about 0.65% Cu) of the Utah Cu mine at Bingham. The Cu is dissolved by  $H_2SO_4$  derived from the decomn. of sulfide mineral and is pptd. upon scrap Fe. The plant has a capacity of 2,000 tons of ore per day. F. W. SMITHER.

**The condensation of zinc from its vapor.** C. H. FULTON. *Bull. Am. Inst. Mining Eng.* 1918, 1649-51.—A critical discussion by E. E. Thum of a paper by F. Cf. C. A. 12, 1868. F. W. SMITHER.

**The condensation of zinc from its vapor.** C. H. FULTON. *Bull. Am. Inst. Mining Eng.* 1919, 109-10.—The author's reply to a discussion by E. E. Thum (preceding abstract). F. W. SMITHER.

**The effect of oxygen upon the precipitation of metals from cyanide solutions.** T. B. CROWE. *Bull. Am. Inst. Mining Eng.* 1918, 1667-8.—Discussion by Clevenger, *et al.* of a paper by Crowe (cf. C. A. 12, 2183). G. T. Hansen states that heating accomplishes practically the same result, as regards removal of air, as applying a vacuum. F. W. SMITHER.

**The effect of oxygen upon the precipitation of metals from cyanide solutions.** T. B. CROWE. *Bull. Am. Inst. Mining Eng.* 1919, 107-9.—Discussion by L. D. Mills of a paper by Crowe (preceding abstract). At the Belmont mill in Tonopah the saving in chemicals alone by the Crowe vacuum process exceeds \$0.15 per ton of ore milled. F. W. SMITHER.

**Roasting for amalgamating and cyaniding Cripple Creek sulfotelluride gold ores.** A. L. BLOMFIELD AND M. J. TROTT. *Bull. Am. Inst. Mining Eng.* 1918, 1668-9.—Discussion by J. M. Tippet of a paper by B. and T. Cf. C. A. 12, 2183. F. W. S.

**Refining gold bullion with chlorine gas and air.** R. R. KAHAN. *Bull. Inst. Mining Met.* 170, 4 pp. (1918).—A modification of Miller's Cl process by combining it with T. K. Rose's method for toughening Au bullion by means of O, gas or air. (The word "refining" is used to denote the removal of Ag and base metals from Au bullion; "toughening" to denote the removal of impurities which make Au bullion brittle.) The author discusses the losses of gold that occur in the Cl process, the major portion being in the final stages. Any improvement in Miller's process must be in the direction of removing the last traces of base metals while there is still a considerable amt. of Ag present in the bullion. Various methods were tried to attain this object, the most successful being as follows: Introduce 2 clay pipe stems into the refining crucible; connect one to an air compressor delivering air at a pressure of 6 or 7 lbs. per sq. in.,

and the other to the Cl generator. At the beginning of the refining operation the max. amt. of air is used, so much as will just avoid the globules of metal being projected through the borax cover, and a very slow stream of Cl. As the operation progresses the vol. of air used is diminished, and that of the Cl is increased, until finally, the air pipe is removed and Cl alone is used. The principle governing the regulation of the air and the Cl is that fumes should be prevented from leaving the borax cover; if the fumes become too voluminous more air must be used and less Cl. It is advantageous to mix the brittle bullion with the most silvery bullion available. It is frequently beneficial to remove the borax cover, and replace it with another cover of fresh borax.

F. W. SMITHER.

**Two instances of mobility of gold in solid state.** E. KELLER. *Bull. Am. Inst. Mining Eng.* 1919, 33-42.—An exptl. study reported in detail. Oxidation tests of auriferous converter Cu (99.29%) and leaded Cu (95.65%) plates show that the Ag is practically immobile. At no stage of the oxidation was all the Au taken up by the oxide scales while some must have retreated and concd. on, or in, the residual plate. The first layer of oxide, or scales, formed in the quenching of cast Cu contains only about  $\frac{1}{10}$  of the Au in the original Cu. A table is given showing the greater speed of oxidation of Cu containing impurities as compared with that of the purer converter Cu. With decreasing Au content in the Ag-Au bead the more marked will be the Au movement in the direction of the retreating surface of the Ag under the solvent action of the  $\text{HNO}_3$ . The bearing of this on the accuracy of the Au assay, and the influence of impurities in Ag on Au mobility are discussed in some detail with a table giving assays of Cu anode residues.

F. W. SMITHER.

**Smelting cyanide silver-precipitate in oil-burning reverberatory furnaces.** K. A. CUNNINGHAM AND A. FEUST. *Mining Sci. Press* 117, 621-4(1918).—A detailed description, with drawings of the furnace, of a method devised to overcome the difficulty caused by the shortage of graphite crucibles in Mexico. Tables are given showing final clean-up, analysis of ppt., consumption of fluxes, in the crucible and reverberatory processes, and the analyses of the 2 types of slag.

F. W. SMITHER.

**Quicksilver operations at Monte Amiata, Italy.** R. STERNER-RAINER. *Chem. Met. Eng.* 19, 770-5(1918).—An account of the development of the Italian deposits of cinnabar beginning with the early developments. The most important operations (described with illustrations) at present are at Abbadia San Salvatore and Siele.

F. W. SMITHER.

**Mercury production at Almaden, Spain.** ROLAND STERNER-RAINER. *Chem. Met. Eng.* 20, 32-5(1919).—"The economic conditions of the Spanish Hg industry are taken up, as well as legal conditions, including markets and the Rothschild contracts. The metallurgical operations of sorting and sampling the ore, the Bustamente and Cermak furnaces and condensers are described briefly."

F. W. SMITHER.

**Phases of iron and steel metallurgy in 1918.** JOHN HOWE HALL. *Iron Age* 103, 27-8(1919).—The subjects reviewed are defects in ingots and their remedies, the Mn problem, autogenous welding, elec. steel, high-grade steel castings, cast steel chain, heat-treated steel castings, oil-burning cupolas, alloy steel helmets.

E. H.

**The principles of open-hearth design.** CHARLES H. F. BAGLEY. *Iron and Steel Inst.*, Sept. 13, 1918; *Engineering* 106, 400-3.—A keen interest is being taken in England in the subject of open-hearth design with the object of raising British practice up to or above the standards of Continental and American practice. B. discusses in a general manner the salient features of correct design. No particularly new facts are presented, many of the suggested improvements being already common practice in the U. S. The article is not such as to permit of brief abstracting. A number of diagrams are shown.

A. L. FIELD.

**Waste heat for steam generation.** THOMAS B. MACKENZIE. *Iron and Steel Inst.*, Sept. 13, 1918; *Engineering* 106, 567-9, 597-9.—A detailed account of the performance of boilers utilizing the heat of the waste gases from open-hearth furnaces. It was found by trial that an induced draft fan, placed beyond the boiler, was necessary to prevent the cooling effect of the heating surface from reducing the draft to too great a degree. The first successful installation consisted of a Babcock and Wilcox water-tube boiler, 1,619 sq. ft. heating surface, in series with an economizer having a heating surface of 720 sq. ft., operated on the waste gases from a 30-ton acid open-hearth furnace. The fan had an impeller 20 in. diam., driven by a variable-speed d. c. motor of 20 brake h. p. The amt. of steam generated was 1,084 lbs., at 101 lbs. pressure with a dryness factor of 0.95 per ton of steel ingots. The efficiencies were: boiler 35.55%, economizer 14.48%, over all 37.80%. The equivalent amt. of elec. energy would be sufficient to roll the steel produced. In later installations, B. and W. boilers, 1,827 sq. ft. heating surface, and economizers of 960 sq. ft. surface were used on 45-ton open-hearth furnaces. The impeller fan was 30 in. diam., driven by a 40 h. p. motor. The amt. of steam generated was 949.3 lbs. per ton of ingots, at 119 lbs. pressure and dryness factor of 0.95. The efficiencies were: boiler 45.83%, economizer 21.25%, over all 49.91%. The electrical equiv. of the energy amounted to 54.2 kw. hrs. per ton of ingots; and the fuel equiv. to 583.2 lbs. coal, of 6,700 cal., per hr. per furnace, assuming an ordinary boiler efficiency of 65%. The fans discharge directly through short funnels into the atm. The furnace chimneys have disk-plate dampers on top, which are kept nearly closed when the boiler, etc., are in operation. The chimney is not entirely closed to prevent possible accumulation of explosive mixt. In the last mentioned installation, the following av. temps. were observed: temp. gases entering boiler, 422.1°; gases entering economizer, 232.4°; gases entering fan, 184.4°; temp. feed water entering economizer, 40.8°; feed entering boiler, 133.5°. The water evapd. from and at 100° per sq. ft. heating surface was 1.84 lbs. per hr. The waste gases entering the boiler, when calcd. to a wet basis, had the following av. compn.: CO<sub>2</sub> 11.27, H<sub>2</sub>O 6.88, N<sub>2</sub> 49.96, excess air 31.89.

A. L. FEILD.

**Gas-fired furnaces for brass melting.** A. FORSHAW. *Foundry* 47, 37-8(1919).—A review and discussion of British practice. Coke-fired tilting furnaces are close competitors of gas-fired furnaces, as they are claimed to have an efficiency of 15%. The author is of the opinion that too much attention is given to the consumption of fuel and too little to other factors that enter into the melting of metals. Gas-fired and coke-fired furnaces are compared as to costs, operation, damage to linings, etc.

F. W. SMITHER.

**Use of oil fuel in the foundry in urgent exceptional circumstances.** A. E. PLANT. *Inst. of Metals* (advance copy), Sept. 11, 1918, 5 pp.—A brief account of work done by the British Expeditionary Forces in field repair shops in producing new parts from scrap and waste material on the spot. The chief points in favor of using oil fuel under the conditions obtaining are: "(1) It is only necessary to have the furnace in operation about 1/4 hr. before the crucible and charge are introduced. (2) The furnace can be put in and out of operation very quickly. (3) Temp. control is easy and consistent. (4) Saving in transport of solid fuel. (5) Utilizing waste oil on the spot. (6) In the case of the "Charlier furnace," borings and scrap can be melted more easily and economically than could be done in crucibles." The waste oil cannot be used again for lubricating purposes without refining, owing to the fact that it contains quantities of finely divided C, mud, and other impurities.

F. W. SMITHER.

**Automatic copper plating.** J. W. RICHARDS. *Bull. Am. Inst. Mining Eng.* 1919, 27-31.—A description, with illustrations of the machines, of the process used by The Metals Plating Co., at Elizabeth, N. J., for the Cu plating of Fe sheets. "The

plating metal is applied to the sheet in the form of a liquid mixt. by means of rolls, such as inking rolls. The sheet, after being coated with the mixt., is automatically carried forward and deposited on a link-belt conveyor, which carries it through a furnace maintained at a temp. well above that of molten Cu. The basic principle involved in this method lies in the application of the plating metal to the sheet while the sheet is cold and then melting the metal in place on the sheet under conditions which are favorable to the formation of the plating. The liquid plating mixt. is composed of either CuO or finely divided Cu, or a mixt. of both, ground to the consistency of a light varnish in a crude oil having an asphaltic base, of a d. of from 14° to 16° Bé."

F. W. SMITHER.

**The metallurgy of the arc weld.** W. E. RUDER. *Gen. Elec. Rev.* 21, 941-6(1918).—The making of a good weld is essentially a metallurgical problem. The factors influencing the quality of a weld are briefly discussed. Photomicrographs show the structure of welds under different conditions. N introduced by the combination of N with Fe vapor either directly or through the formation and decompn. of oxides of N, is believed to be the chief source of brittleness. The needle-like structure usually associated with N-bearing steels is shown to be only one phase of the N-Fe combination, and is frequently masked by rapid cooling or the presence of carbon. In the absence of accurate knowledge of their exact nature, these lines are termed N-lines rather than nitride lines. N or possibly  $Fe_3N_2$  appears to form a solid soln. with Fe. There is some evidence that C also may enter into this solid soln.

W. E. RUDER.

**Notes on regulations for arc welding.** H. M. SAYERS. *Electrician* 81, 715-7 (1918).—This paper deals chiefly with the necessary precautions during welding operations, protection of the eyes, protection from shock, etc.

C. G. F.

**Lloyd's experiments on electrically welded joints.** H. JASPER COX. *Gen. Elec. Rev.* 21, 864-70(1918).—After briefly referring to the functions of Classification Societies, C. describes the test made upon arc welded joints to det. the acceptability of that type of joint in ship construction. The requirements of Lloyd's are set forth and the testing machines employed together with the method of performing the test are described. The summary of the results of modulus of elasticity, ultimate strength and alternating stress tests show conclusively the reliance which can be placed in this type of joint.

W. E. RUDER.

**Microstructure of iron deposited by electric arc welding.** GEORGE F. COMSTOCK. *Bull. Am. Inst. Mining Eng.* 1919, 43-50.—Conflicting opinions have been expressed concerning the identity of the needles or small crystals present in oxyacetylene and electric welds. The results here described were obtained in the microscopic examination of etched specimens of an electric weld; photomicrographs of the structure are shown. The needles or pale crystals, which are typical of steel fusion, may occur very abundantly in iron containing only 0.04% C and when annealed thoroughly and slowly cooled, the needles will diffuse into the steel from the welded metal but do not merge with the pearlite of the steel. From this fact, the conclusion is drawn that the crystals are probably those of iron nitride. Boiling in Na picrate etching fluid will not serve to differentiate between nitride and carbide or sulfide in a polished specimen of steel.

W. T. H.

**Development of grain boundaries in heat-treated alloy steels.** R. S. ARCHER. *Bull. Am. Inst. Mining Eng.* 1919, 51-5.—In the microscopic examination of air-craft engine parts, the usual etching media do not disclose any but gross defects in heat treatment. Photomicrographs are shown which were obtained after etching for from 5 to 25 min. in a 4% soln. of picric acid in alc. and then rubbing off the carbonaceous smudge on moist broadcloth or kersey. With this etching agent, the grain bounda-

ries of Cr-Ni and of Cr-V steels hardened to about 300° Brinell are brought out clearly.

W. T. H.

**Volatility of the constituents of brass.** JOHN JOHNSTON. *Bull. Am. Inst. Mining Eng.* 1919, 96-7.—Discussion of paper abstracted in *C. A.* 12, 1758. J. W. Richards pointed out the need of vapor-tension curves and heats of combination in the study of brass.

W. T. H.

**Pure carbon-free manganese and manganese-copper.** ARTHUR F. BRAID. *Bull. Am. Inst. Mining Eng.* 1919, 97.—A brief discussion of the use of Mn and Mn-Cu in the manufacture of non-ferrous alloys. Cf. *C. A.* 13, 222.

W. T. H.

**The constitution of the tin bronzes.** SAMUEL L. HOYT. *Bull. Am. Inst. Mining Eng.* 1919, 101-2; cf. *C. A.* 13, 225.—A brief discussion of the paper.

W. T. H.

**The action of reducing gases on hot solid copper.** NORMAN B. PILLING. *Bull. Am. Inst. Mining Eng.* 1919, 103-7; cf. *C. A.* 12, 2532.—In the discussion of this paper, W. H. Bassett pointed out that the effect of H on Cu has been known for some time as evidenced by a popular article written by Heyn in 1904. B. disagrees with P. regarding some of the theoretical points.

W. T. H.

**A comparison of grain size measurement and Brinell hardness of cartridge brass.** W. H. BASSETT AND C. H. DAVIS. *Bull. Am. Inst. Mining Eng.* 1919, 79-81.—The purpose of this investigation was to det. the grain size of cartridge brass, its relation to Brinell hardness and to collect data for the aid of those concerned in the inspection of such brass. Two alloys were studied. The first was taken from regular mill stock that had been rolled from 14.7 mm. to 9.5 mm. gage, corresponding to a reduction of 35.1%. It contained 69.2% Cu, 30.76% Zn, 0.02% Fe and 0.02% Pb. The second alloy was taken from mill stock of 8.25 mm. gage and was rolled to get 4 bars reduced 2, 4, 6 and 6 B. & S. nos., respectively. This second alloy contained 68.48% Cu, 31.47% Zn, 0.02% Pb and 0.03% Fe. The grain sizes of the annealed alloy agreed closely when the previous heat treatment and reduction by rolling were made to correspond. The difference in thickness (9.4 to 3.3 mm. gage) does not appreciably affect the grain size or Brinell hardness. The grain size of the brass when annealed at low temps. is affected greatly by the previous grain size and by the reduction in rolling which the brass has undergone. The grain size and Brinell data for the several conditions described, when plotted against the temp., give curves that approach as a limit the curve of metal annealed after hard rolling. It would seem desirable to select as standard for grain size, as detd. by the temp. of annealing, specimens that have been reduced by rolling at least 50%. In the case of the cartridge brass with 68% Cu and 32% Zn, Brinell hardness does indicate grain size. At low annealing temps., the grain size is influenced by the grain size of the previous anneal. The finer the grain size of the previous anneal, the more closely will the curve of Brinell hardness vs. grain size approach the standard curve. Since grain size is influenced by that of the previous anneal and also by the reduction by rolling previous to annealing, it is better to det. the hardness by Brinell measurement than to attempt to judge it by the grain size.

W. T. H.

**Does forging increase the density of steel?** H. E. DOERR. *Bull. Am. Inst. Mining Eng.* 1919, 79-81.—Many practical men believe that forging greatly compresses or consolidates steel and would therefore, answer this question in the affirmative. The data here given, which were obtained by careful measurements on 10 ingots of basic open-hearth steel, show that if the original ingot is entirely free from cavities there is very little, if any, change in d. as a result of forging.

W. T. H.

**Notes on babbitt and babbitted bearings.** JESSE L. JONES. *Bull. Am. Inst. Mining Eng.* 1919, 95-6; cf. *C. A.* 12, 1965.—In the discussion of this paper the fact

was brought out that fluidity has a good deal to do with the practical value of babbitt metal. Dr. Frary's alloy of Pb hardened with Ca and Mg has not proved wholly successful in practice on account of the difficulty of pouring large castings.

W. T. H.

**Ferrous alloys.** I. JEAN ESCARD. *Rev. gén. sci.* 29, 673-80(1918).—The method of manufacture, chem. compn., properties and uses of Fe-Cr, Fe-Si, and Fe-Mn alloys are discussed in considerable detail.

W. T. H.

**The relative corrosion of alloys.** R. B. FEHR. *J. Am. Soc. Mech. Eng.* 40, 829-33 (1918).—To det. the extent of corrosion, the results have been in the past expressed by (a) loss in wt., (b) % loss of wt., (c) loss of wt. per unit of exposed surface; and (d) appearance as judged by the naked eye or with the aid of a lens. It is proposed as a better standard of comparison, to represent the corrodibility by a factor, K, which is obtained by dividing the % loss in wt. by the ratio of exposed surface in sq. cm. to the vol. of the specimen in cc. To illustrate the value of this method of comparison, values are given which are compared with the same results expressed by the other methods. Values are also given for the corrodibility of 5 alloys in tap water, 1% salt soln. and in 10% salt soln. It is evident that very consistent results can be obtained by this method when the duration of the test is 1 week for the more corrosive alloys and about 2 mos. for the more resistant alloys. In fact, 1 day is quite enough to classify groups of alloys in the order of their corrodibility for such corroding media as will cause enough loss in wt. to be detd. by an ordinary analytical balance.

W. T. H.

**A new principle for producing metal coatings.** M. U. SCHOOP. *Z. angew. Chem.* 31, I, 204(1918).—A "metal splashing" process has been devised for coating with Pb. The extremity of a Pb tube connected with a CO<sub>2</sub> bottle is held in a Bunsen flame. Melting Pb is acted upon by the CO<sub>2</sub> gas brought through the lead tube and is splashed up, in form of very small drops, against the object to be coated. In this way a uniform and adhering coating is obtained which consists of normal, pure, sound Pb. The purity of the Pb coating is secured by using an inert or reducing gas whereby all oxidation is prevented. The adherence obtained is so great that a sheet of Fe covered with Pb according to this process may be bent without scaling off of the Pb.

TH. VERHEGGEN.

**Splashing soldering process.** WITOLD KASPEROWICZ. *Chem. Ztg.* 42, 20(1918).—The metal splashing process can find application as a soldering process. The soldering wire is brought into the flame by means of a driving mechanism so that the flame, which is under pressure, effects the carrying up of the soldering metal.

TH. VERHEGGEN.

The importance of particle-size reduction before sampling for assay (ALLEN) 7. Checking calibration of thermocouples and pyrometers (ANON.) 1. A neon arc lamp for direct current (SCHROETER) 4.

GUENTHER, H. AND SCHOOP, M. U.: *Das Schoopsche Metallspritzverfahren, seine Entwicklung und Anwendung nebst einen Ueberblick über seine Stellung zu den übrigen Metallisierungsmethoden und einen Abriss seiner Patentgeschichte.* Stuttgart: 130 illus. 266 pp. 9 M.

**Flotation separation of sulfide ores.** A. G. BERTS. U. S. 1,286,922, Dec. 10. In flotation of sulfide ores, such as those which may contain Cu<sub>2</sub>S, Cl is added to an aq. flotation bath to increase the buoyancy of the particles of sulfides by oxidation of a portion with formation on the particles of a thin superficial film containing free S.

**Treating ores.** O. REECE. Brit. 120,044, Oct. 7, 1918. Fine ores, concentrates, slimes, dust, etc., are prepd. for smelting in a blast furnace by mixing them with binding and fluxing materials such as CaO, cement, gypsum, dolomite, S, or mixts. of these, damping with H<sub>2</sub>O, allowing the mixt. to stand for a time, briquetting in molds under pressure, and then subjecting the briquets to the action of steam under pressure. In some cases, combined S present in the original material may serve as the binding and fluxing agent.

**Treating copper ores.** N. C. CHRISTENSEN. U. S. 1,286,531, Dec. 3. The pat. relates to the treatment of Cu ore which may also contain Au or Ag. It is especially adapted for application to oxidized or partly oxidized or roasted sulfide ore. The ground ore is agitated with a solution of SO<sub>2</sub> in H<sub>2</sub>O until all the Cu is brought into soln. The mixt. is then heated to boiling and agitated until the excess SO<sub>2</sub> is driven off and the Cu pptd. as cuprocupric sulfite. The latter is then sepd. by flotation. CaO may be added prior to boiling to cause pptn. of CuSO<sub>4</sub> as sulfite during the boiling. The Au and Ag values are also caused to float in this method.

**Treating copper ores.** N. C. CHRISTENSEN. U. S. 1,286,532, Dec. 3. A thick aq. pulp of Cu ore is treated with SO<sub>2</sub> in the presence of an excess of metallic Cu at a temp. of about 100° and the cupro-cupric sulfite formed and excess of Cu are removed from the gang by flotation.

**Smelting sulfide ores of copper.** G. N. KIRSEBOM. U. S. 1,286,652, Dec. 3. An unroasted sulfide ore rich in Cu is smelted with a roasted sulfide ore containing Cu in the presence of SiO<sub>2</sub> and of a quantity of coke sufficient to effect reduction of Fe<sub>2</sub>O<sub>3</sub> to FeO, in an elec. resistance furnace, to obtain a rich Cu mat suitable for reduction in a Bessemerizing furnace.]

**Treating ores containing molybdenum.** A. L. PELLEGRIN. U. S. 1,286,400, Dec. 3. Refractory ores containing oxidized compds. of Mo, V, U or similar metals are reduced to a fineness of 150 mesh, mixed with strong H<sub>2</sub>SO<sub>4</sub> and the acid soln. is sepd. and neutralized and the metal pptd. from it by H<sub>2</sub>S.

**Recovering metals from ores.** A. H. SINN. Norw. 28,713, Apr. 8, 1918. Au, Ag and Cu ores are crushed and sepd. in such manner that the portions passing through the sifting cloth attached to the fine crusher are sepd. by air blast in a special app., the non-metallic dust being removed and the coarser particles being returned to the app. for re-treatment with fresh ore. The metallic particles remaining in the sifting cloth in the crusher are removed and treated chem.

**Separating lead and zinc from ores.** C. E. CORNELIUS. Swed. 43,987, May 1, 1918. The process is dependent upon the different temps. of reduction and boiling of the Pb and the Zn.

**Smelting iron ore.** G. C. CARSON. U. S. 1,287,221, Dec. 10. In smelting Fe ore with natural gas or petroleum or both, the fuel is dehydrogenated, soot deposited is freed from S by heating to form CS<sub>2</sub> and the C thus obtained from the fuel is used to deoxidize the ore and produce metallic Fe.

**Steel alloy.** J. W. WEITZENKORN. U. S. 1,287,153, Dec. 10. A steel alloy is formed containing about 0.35% C, 1% Cr, 0.15% V, and 0.75-1.00% Mo. The alloy is especially adapted for machine parts where toughness is required.

**Alloy for bearings.** W. D. BERRY. U. S. 1,286,921, Dec. 10. A bearing alloy is formed of Cu 60-85, Pb 1-35 and Sb 3-20%; preferably, Cu 79, Pb 14, Sb 6 and P 1%. Small amts. of Ni, Mn, Si or Mg may be added.

**Fluxes.** AKT.-GES. FÜR AUTOGENE ALUMINIUM SCHWEISSUNG. Brit. 120,005, May 28, 1918. A flux for use in autogenous welding of Al and its alloys consists of a

mixt. of alkali metal halides comprizing at least 3 different halogens, of which F is one. An example contains 4 parts of KCl, 3 of NaCl, and 1 each of LiCl, KBr, and NaF. In some cases, an alkali metal iodide may be added. Cf. 24,096, 1907, 24,283, 1907, 8,778, 1909, and 29,084, 1910.

## 10. ORGANIC CHEMISTRY.

CHAS. A. ROUILLER.

The isomeric lactones, caryophyllin and urson. FRANCIS D. DODGE. *J. Am. Chem. Soc.* 40, 1917-39(1918).—Caryophyllin (a) can be freed from the amorphous impurities which always accompany it when prepd. by the methods hitherto described by heating with aq. alc. KOH, filtering hot and reprecip. the K salt which crystals out from cold MeOH with H<sub>2</sub>O or by decolorizing a slightly alk. soln. of (a) in MeOH with concd. aq. KMnO<sub>4</sub>. From the soln. of the K salt in boiling MeOH and a slight excess of HCl, pure (a) crystals slowly. It seps. from EtOH in needles resinous to the touch, apparently with H<sub>2</sub>O, m. (anhydrous) about 310°, sublimes *in vacuo* 280-300° and under atm. pressure, with partial decompn., above 310°, sol. in 35 parts boiling 95% EtOH, 106 parts at 20°, 65 parts Et<sub>2</sub>O, 118 parts CHCl<sub>3</sub>, 180 parts Me<sub>2</sub>CO, 235 parts MeOH, insol. in aq. alkalis, sol. in 4 parts of 0.5 N KOH in MeOH, [α]<sub>D</sub><sup>20</sup> 54.5° (0.77 g. in 10 cc. alc.). The K salt shows [α]<sub>D</sub><sup>20</sup> 63.40° (0.224 g. in 10 cc. 95% alc.), [α]<sub>D</sub><sup>24.6</sup> 67.70° (0.9519 g. in 10 cc. MeOH). In alc. (a) can be titrated with phenolphthalein, especially if towards the end the soln. is chilled until the greater part of the salt has crystd. out. The alc. soln. exactly neutral when cold becomes alk. on heating. The acid value found was 123-124.8, whence it is probable that the formula for (a) is C<sub>20</sub>H<sub>34</sub>O<sub>3</sub>, with one CO<sub>2</sub>H or lactone group, and the behavior of the salts and the formation of two Ac derivs., described below, are in agreement with the lactone structure,

an aq. alc. KOH soln. of (a), sol. in 36 parts EtOH at 20° and 2.5 parts MeOH, partially hydrolyzed by digestion with H<sub>2</sub>O; the alkali liberated can be titrated in the presence of (a); CO<sub>2</sub> ppts. (a) from the alc. soln. Various other metallic salts can be obtained by pptn. from alc. solns. of the alkali salts with alc. solns. of metallic chlorides or acetates. The calcium, lead, magnesium, zinc and silver salts have been prepd. Caryophyllin diacetate (diacetylcaryophyllinic acid), C<sub>20</sub>H<sub>47</sub>(OAc)<sub>2</sub>CO<sub>2</sub>H, is obtained by heating (a) with 4 parts Ac<sub>2</sub>O 6 hrs. at 100°, decomp. the Ac<sub>2</sub>O with ice water, washing with dil. Na<sub>2</sub>CO<sub>3</sub>, drying *in vacuo*, dissolving in Et<sub>2</sub>O (avoiding all heating) and evap. at a low temp.; acid value, cold, 100.8; sapon. value after heating, 297.7. Heated at 185-90° in a slow current of air it loses AcOH (8.8%; calcd., 10.7%). The soln. in 12 parts of glacial AcOH at 100° deposits on cooling snowy crystals consisting almost entirely of the monoacetate; the latter is easily obtained by recrystg. the diacetate from 35-40 parts boiling alc. and seps. in needles with about 5 H<sub>2</sub>O, quickly efflorescing in the air, m. (anhydrous) 260-5° (apparent decompn.); acid value, cold, 105-111.7; sapon. value, 215-27; heated with 3 parts Ac<sub>2</sub>O 1-2 hrs. at 100° it is entirely converted into the diacetate; its potassium salt seps. in needles from EtOH-Et<sub>2</sub>O. In the prepn. of the diacetate is obtained a very slightly sol. substance showing no acid value and a sapon. value of 223.2 and giving the K salt of (a) on continued heating with alc.

The analysis of Herzog's carbaminic ester and Ac deriv. of (a) (*Ber.* 13, 800(1880))

agrees as well, if not better, with the formula for (a) proposed by D. When 8 g. caryophyllic acid (b) (Mylius, *Ber.* 6, 1053(1873)) in 50 cc. of 0.5 N alc. KOH is treated with 2 g. AcOH, the acid potassium salt,  $C_{27}H_{44}O_7(CO_2H)CO_2K \cdot 4H_2O$ , slowly seps.; acid value (anhydrous) 187.5. If (b) is heated 1-2 hrs. at 100° with 3 parts Ac<sub>2</sub>O there are obtained crystals m. 210-3°, with an acid value (cold) 215.3-224.5 and a sapon. value 316-323; these are much lower than would be expected and it is suggested that secondary reactions have taken place during the acetylation, with elimination of 1 mol. CO<sub>2</sub> and lactone formation by the other two CO<sub>2</sub>H groups, the product being an acetyldilactone,  $C_{25}H_{40}O_6$ , with a calcd. acid value 218.1 and sapon. value 327.2. The product of its sapon. is not the original (b) but apparently a new acid or a mixt. of acid and lactones, partially sol. in alkali carbonates and wholly in warm dil. alkalies. Two samples of urson (c), one Merck's "Urson puriss," and another prepd. from bearberry leaves by the method described above for the purification of (a), were studied. In strictly chem. properties no differences were observed between (a) and (c) but (c) differs from (a) in that its K salt is very sol. in alc., the K salts of the mono- and diacetates are slightly sol. in alc., the monoacetates are slightly sol. in alc., the monoacetate crysts. in prisms stable in air and sol. to the extent of 1.4% in alc. at 25°, the Mg salt is easily sol. in alc. and the (c) itself is easily sol. in alc. NH<sub>3</sub>. The difference in soly. of the K salts can be utilized to effect a partial sepn. of (a) and (c). These differences appear to D. sufficient to warrant the assumption that (a) and (c) are isomers of very similar structure. Gentiol, lactucon, vitin and encarpol are, judging from the descriptions of their properties in the literature, possibly identical with (a) or (c).

CHAS. A. ROUILLER.

**Quinone-phenolate theory of indicators. Spectrophotometric study of the "end points" and "fading" of phenolsulfonephthalein indicators.** CHARLES L. BRIGHTMAN, J. J. HOPFIELD, M. R. MEACHAM AND S. F. ACREE. *J. Am. Chem. Soc.* 40, 1940-4 (1918).—The details of the spectrophotometric method used will be published later; the general plan was to find the wave lengths at which the indicator solns. give a transmission of 20, 40, etc., % and to calc. the corresponding absorption indexes and draw a curve through these points. Phenolsulfonephthalein (a) and the tetra-NO<sub>2</sub> (b) and tetra-Br (c) derivs. were studied. These are twice as deeply colored as phenolphthalein in alkalies and show sharper color changes. The excess of alkali necessary to produce the "end point" does not cause any appreciable fading in either short or long time periods in the case of (a) or (c). The color of (a) in phosphate buffer solns. does not fade appreciably in considerable time periods. Standardized stock solns. of (a) can be kept without appreciable change in an ice box or even at ordinary temp. if care is taken to prevent contamination. Different samples of the same lot of well mixed solid (a) give the same absorption index when treated with an excess of alkali. Excess of alkali in solns. of (b) causes a fading of the intense red to a light yellow color, the time of fading depending upon the amt. of alkali and other exptl. conditions.

CHAS. A. ROUILLER.

**Tetramethylammonium azide.** FRANK V. FRIEDLANDER. *J. Am. Chem. Soc.* 40, 1945-7(1918).—*Tetramethylammonium azide*, prepd. by slowly adding somewhat less than 1 mol. of 1% NMe<sub>4</sub>I to a suspension of AgN<sub>3</sub> in cold H<sub>2</sub>O with thorough but cautious shaking, filtering, concg. on the H<sub>2</sub>O bath to the point of crystn. and allowing to cool, is fairly stable, does not explode when struck with a hammer, ground in a mortar or dropped on a hot plate; begins to decomp. about 125°, more rapidly at higher temps. with the evolution of vapors of fishy odor; 1 cc. of the satd. solns. at 20° contains approximately the following amts. (g.) of the salt: H<sub>2</sub>O, 0.5; EtOH, 0.05; MeOH, 0.02; C<sub>6</sub>H<sub>6</sub>, 0.004; CHCl<sub>3</sub>, 0.001; Et<sub>2</sub>O, 0.0005. With CCl<sub>4</sub> is formed a two liquid layer system, the lower layer containing at 20° in presence of an

excess of the solid phase suspended in the upper layer about 0.005 g. per cc. The crystals of the salt belong to the tetragonal system,  $a : c = 1 : 0.7245$ , with prismatic habitus, angle (110) to (111) =  $59^{\circ} 36'$ , parallel extinction, very strong double refraction and negative optical character. Preliminary expts. on the thermal treatment of the salt gave no positive indications of any mol. transformation into  $\text{Me}_3\text{NN}:\text{NNMe}_3$ .

C. A. R.

**Derivatives of trihalogen tertiary butyl alcohols. II. The propionic and butyric esters of tribromotertiarybutyl alcohol (brometone).** T. B. ALDRICH. *J. Am. Chem. Soc.* 40, 1948-50(1918); cf. *C. A.* 11, 337.—*Tribromotertiarybutyl propionate*, from 4 parts of the alc. and 1 part  $\text{EtCOCl}$ , m.  $27^{\circ}$ , decompd. slowly by boiling  $\text{H}_2\text{O}$  or 10%  $\text{H}_2\text{SO}_4$ , more rapidly by boiling 10%  $\text{NaOH}$ , in a few mins. by an excess of boiling concd.  $\text{HNO}_3$ , volatilizes very slowly in the air. *Butyrate* b<sub>14</sub> 144-5°. Neither ester appears to have anesthetic properties or to exert any very appreciable action upon the heart or general circulation.

C. A. R.

**Organic chemical reagents. II. Amylene, tertiary amyl alcohol.** ROGER ADAMS, O. KAMM AND C. S. MARVEL. *J. Am. Chem. Soc.* 40, 1950-5(1918); cf. *C. A.* 12, 2321.—Detailed description of the prepn. of amylene by the  $\text{H}_2\text{SO}_4$  and the pyrogenic catalytic methods as worked out at the Univ. of Illinois. By the first method a student provided with eight 3-l. flasks and the proper reflux condensers can prep. 2-3 lbs. amylene in 1 day; by the second method, with an app. which can be easily made by any plumber and which can be used for many other catalytic processes, 5 lbs. amylene can easily be made from  $\text{AmOH}$  in 1 day at a cost much below Kahlbaum's pre-war price. From 325 g. of the amylene, 275-300 g. tertiary amyl alc., b.  $100-3^{\circ}$ , can be obtained with  $\text{H}_2\text{SO}_4$ .

C. A. R.

**Identification of the cinchona alkaloids by optical crystallographic measurements.** EDGAR T. WHERRY AND ELIAS YANOVSKY. *J. Am. Chem. Soc.* 40, 1955-6(1918).—Correction of minor errors occurring in the paper abstracted in *C. A.* 12, 1780.

C. A. R.

**Relative activities of methyl, ethyl, and propyl iodides with sodium  $\alpha$ - and  $\beta$ -naphthoxides.** HENRY E. COX. *J. Chem. Soc.* 114, 666-74(1918).—C. studied the velocity of the reaction between  $\text{MeI}$ ,  $\text{EtI}$ , and  $\text{PrI}$  and  $\alpha\text{-C}_{10}\text{H}_7\text{ONa}$  (A) and  $\beta\text{-C}_{10}\text{H}_7\text{ONa}$  (B) in abs. alc. at  $40^{\circ}\text{C}$ . The reaction is a bimol. one of a special type in which the velocity is dependent upon the initial concn. Some evidence is presented to show that both (A) and (B) undergo alcoholysis in  $\text{EtOH}$  soln. (A) is more reactive towards the alkyl iodides than is (B). If an excess of  $\alpha$ - or  $\beta$ -naphthol is present in the reaction mixt. the velocity coeff. is decreased. The velocity of reaction in each case increases with the diln., the most marked increase being noted in the case of  $\text{MeI}$ . The empirical equation (cf. Hecht, Conrad, and Brückner, *Z. physik. Chem.* 5, 289),  $Kv = K_1 + a \log v$  (where  $v$  is the vol. in l. containing 1 mol. of the reacting substances) may be used to express the velocity of the reactions, within certain limits. The equation is applicable with  $\text{EtI}$  and  $\text{PrI}$  up to the diln.  $v = 40$ , and with  $\text{MeI}$  up to dilution  $v = 10$  in the case of (A) and  $v = 7$  in the case of (B). At higher dilns. the reactivity of  $\text{MeI}$  increases.  $\text{MeI}$  is several times more active than is  $\text{EtI}$ , which in turn is more active than  $\text{PrI}$ . Summarized tabulated data are given.

LOUIS E. WISE.

**Azo dyes derived from *m*-phenetidine.** F. REVERDIN, A. RILLIET AND C. VERNET. *Arch. sci. phys. nat.* 46, 74-80(1918).— $3\text{-H}_2\text{NC}_6\text{H}_4\text{OEt}$  couples with  $\text{PhN:NCl}$ , to form  $\text{benzeneazo-}m\text{-phenetidine}$  (A),  $\text{PhN:N.C}_6\text{H}_4(\text{OEt})(\text{NH}_2)$ , orange leaflets, m.  $84-5^{\circ}$ . Since the reduction of (A) with  $\text{NaHSO}_3$  yields a typical *p*-diamine, it is evident that the coupling takes place in a *p*-position to the  $\text{NH}_2$  group. The hydrochloride of (A),

m. 152-3°; the *acetyl derivative*, reddish brown prisms, m. 135°; the *benzoyl derivative*, flat, orange needles, m. 146°. With suitable precautions (A) may be diazotized and coupled with phenols and amines. (A) is dissolved in concd.  $\text{H}_2\text{SO}_4$ , and the soln. cautiously dild. to prevent pptn., and diazotized at 0-2°. The product couples with phenols in the presence of  $\text{Na}_2\text{CO}_3$ , and with amines in the presence of  $\text{AcONa}$ . The following dyes were formed from (A): (with  $\alpha$ -naphthol)  $\text{PhN}_2\text{C}_6\text{H}_4(\text{OEt})\text{N}:\text{N}-$   
 $\text{C}_{10}\text{H}_7\text{OH}$ , brown needles from  $\text{AcOH}$ , m. 172°; (with *R*-salt),  $\text{PhN}:\text{NC}_6\text{H}_4(\text{OEt})\text{N}:\text{N}-$   
 $\text{C}_{10}\text{H}_4(\text{OH})(\text{SO}_3\text{H})_2$ , reddish violet powder, dyeing silk a bright purplish red and wool  
 a somewhat less brilliant shade; (with naphthionic acid),  $\text{PhN}_2\text{C}_6\text{H}_4(\text{OEt})\text{N}_2\text{C}_{10}\text{H}_6-$   
 $(\text{NH}_2)(\text{SO}_3\text{H})$ , dark brown powder, dyeing silk a reddish brown. Many other analogous  
 dyes were also prepd., but only a few of them are mentioned and none of them appears  
 to have more than academic interest. The interaction of 3- $\text{HO}_2\text{S}\cdot\text{C}_6\text{H}_4\text{N}_2\text{Cl}$  with  
 3- $\text{H}_2\text{NC}_6\text{H}_4\text{OEt}$  gave rise to *m-sulfobenzeneazo-m-phenetidine* (C), reddish brown micro-  
 needles, m. 214-5°. (C) may be diazotized by dissolving in  $\text{Na}_2\text{CO}_3$ , neutralizing  
 the soln. with a mineral acid (which ppts. (C) in finely divided form) and treating the  
 amorphous product with  $\text{NaNO}_2$ . The diazonium salt (D) thus formed is cryst. (D)  
 when coupled with 1,3,6,8-(HO)(HO $_2\text{S}$ ) $_2$ ( $\text{H}_2\text{N}$ ) $\text{C}_{10}\text{H}_2\text{N}:\text{N}\cdot\text{C}_6\text{H}_4\text{NO}_2$  gave rise to the tris-  
 azo dye: (HO $_2\text{S}$ ) $\text{C}_6\text{H}_4\text{N}_2\cdot\text{C}_6\text{H}_4(\text{OEt})\text{N}:\text{NC}_{10}\text{H}_2(\text{OH})(\text{NH}_2)(\text{SO}_3\text{H})_2\cdot\text{N}_2\cdot\text{C}_6\text{H}_4\text{NO}_2$ , dark  
 green powder dyeing wool bluish green to greenish black. By coupling the diazonium  
 salt derived from 4- $\text{O}_2\text{NC}_6\text{H}_4\text{N}:\text{N}\cdot\text{C}_6\text{H}_4(\text{OEt})\text{NH}_2$  with 1,8,3,6-(HO) $_2$ (HO $_2\text{S}$ ) $_2\text{C}_{10}\text{H}_4$ , a  
 dark brown powder (E) was obtained, which dyed wool a dull violet shade. On reduc-  
 tion with  $\text{Na}_2\text{S}$ , (E) gives rise to  $\text{H}_2\text{N}\cdot\text{C}_6\text{H}_4\text{N}:\text{NC}_6\text{H}_4(\text{OEt})\text{N}:\text{N}\cdot\text{C}_{10}\text{H}_2(\text{OH})_2(\text{SO}_3\text{H})_2$ ,  
 a brown powder that dyes wool blue. 3- $\text{H}_2\text{NC}_6\text{H}_4\text{OEt}$  apparently does not couple  
 readily with diazo compds. of very high mol. wt.

LOUIS E. WISE.

**Benzoylation of some aromatic hydroxy and amino derivatives.** FRÉDÉRIC REVERDIN. *Helvetica chimica acta* 1, 205-9(1918).—A very convenient benzoylation reaction is described. The phenol or amine is mixed with the theoretical amt. of  $\text{BzCl}$  and 2-3 drops of concd.  $\text{H}_2\text{SO}_4$  are added to the mixt., which is then heated moderately on the steam bath (or at a lower temp). By this method R. prepd. 1,3-(BzO) $_2\text{C}_6\text{H}_4$ , leaflets, m. 117°, in 70% yield together with smaller amts. of 1,3-(HO)(BzO) $\text{C}_6\text{H}_4$ , m. 132°; 1,2-(BzO) $_2\text{C}_6\text{H}_4\cdot\text{CO}\cdot\text{C}_6\text{H}_4\cdot\text{CO}$ , yellow needles, m. 210-11°; 2,4-(O $_2\text{N}$ ) $_2\text{C}_6\text{H}_3\text{NHBz}$ ,  
 needles, m. 201-2°; 1-BzNHC $_6\text{H}_4\cdot\text{CO}\cdot\text{C}_6\text{H}_4\cdot\text{CO}$ , microneedles, m. 246° and 2-BzNH-  
 $\text{C}_6\text{H}_3\cdot\text{CO}\cdot\text{C}_6\text{H}_4\cdot\text{CO}$ , needles, m. 227°. All of the above compds. have been previously  
 described either in the chem. literature or in patents. They are all readily hydrolyzed  
 by concd.  $\text{H}_2\text{SO}_4$  at the temp. of the steam bath.

LOUIS E. WISE.

**Transformation of levoglucosane into dextrin.** AMÉ PICTET. Univ. Geneva. *Helvetica chimica acta* 1, 226-30(1918).—When levoglucosane (A) is rapidly heated to 180° it melts to a clear liquid, which shows no change on further rapid heating until 270° is reached, whereupon a deep-seated decompn. takes place, with the formation of  $\text{H}_2\text{O}$ ,  $\text{HCO}_2\text{H}$ ,  $\text{AcOH}$ ,  $\text{Me}_2\text{CO}$  and phenols. If, however, (A) in the liquid phase is kept for about 0.5-1 hr. at 240°, polymerization takes place. The polymer appears to be a *dextrin* (B), which may be purified by soln. in  $\text{H}_2\text{O}$ , and pptg. with alc. (B) can be much more conveniently prepd. by mixing (A) with a small amt. of Pt black (prepd. by Loew's method, *Ber.* 23, 289) and heating the mixt. to 180°. The polymerization proceeds very smoothly and rapidly at this temp. (B) formed by this method is almost

colorless, and very nearly pure. It has  $[\alpha]_D^{111.9'}$  and appears to have the formula  $(C_6H_{10}O_4)_4$ . Its aq. soln. gives no coloration with I, and is not pptd. by  $Na_2SO_4$ , gallic acid,  $Br-H_2O$  or  $(AcO)_2Pb$ . Fehling soln. is very slightly reduced after long boiling with (B). When treated with aq.  $H_2SO_4$ , (B) is hydrolyzed to glucose. (B) is not fermented by yeast, and appears to be related to an achroodextrin obtained from starch by treatment with  $(CO_2H)_2$  (cf. Wacker, *Ber.* 42, 2675). In some respects it is also similar to the artificial dextrins described by Grimaux and La Fevre (*Compt. rend.* 103, 146(1886)).

LOUIS E. WISE.

**Different processes for the production of quinone.** CLAUDIUS CHAVRAU. *Rev. prod. chim.* 21, 288-92(1918).—A critical review of the principal methods used in the manufacture of quinone. C. has made a comprehensive study of the quinone synthesis from the industrialist's standpoint and some of his exptl. data are given. The method of Ludwig and Guttermann (ref. not given), which involves the oxidation of  $PhNH_2$  in 2 stages by means of  $CrO_3$ , gives a 50-60% yield of quinone. Other methods involving the oxidation of  $PhNH_2$  are of little industrial interest. Of the electrolytic methods for the oxidation of  $C_6H_6$  to quinone, that of Kempf (D. R. P. No. 117251) appears to be the best. The reaction is carried out in a  $H_2SO_4-C_6H_6$  emulsion, with a Pb cathode and  $PbO_2$  anode, using a current of 3-4 amp. per sq. dcm. of anode (e. m. f. 3-4 v.). Of the  $C_6H_6$  oxidized, 65-70% is converted into quinone. The electrolytic method presents advantages over the  $CrO_3$  method since starting materials are cheaper, and since the operation is more readily controlled.

LOUIS E. WISE.

**Manufacture of monochloroacetic acid.** GUY CHAZEL. *Rev. prod. chim.* 21, 267-8(1918).—A brief article describing the production of  $CH_2ClCO_2H$  on a com. scale. No new data are given.

LOUIS E. WISE.

**Syntheses by means of sodamide. VII. Preparation and study of certain monoalkyl and dialkylcamphors and their derivatives.** A. HALLER AND J. LOUVRIER. *Ann. chim.* 9, 189-251(1918).—A collective article (cf. C. A. 8, 2147).

LOUIS E. WISE.

**Products of the condensation of phenols with aldehydes.** A. HUTIN. *Mon. sci.* 8, II, 217-23(1918).—A descriptive article giving no new exptl. data.

LOUIS E. WISE.

**The double acid from normal and allo-cinnamic acids.** A. W. K. DE JONG. *Proc. Acad. Sci. Amsterdam* 20, 1230-3(1918).—The double acid may be prepd.: (1) by allowing a soln. satd. at room temp. with respect to both the normal and the allo-acids, to cryst. slowly; (2) by prep. a hot soln. satd. with both acids, and allowing the soln. to cool; (3) by prep. an aq. soln. of Na *n*-cinnamate (10 g. per l.) exposing the soln. to light in an open vessel (for several months), evapg. to dryness, liberating the mixed acids by means of concd. HCl, and crystg. the double acid from petr. ether, from which it is deposited in the form of rhombs. In a series of preliminary expts. de J. was able to isolate but one double acid, although 2 modifications of the *n*-acid and 3 forms of the allo-acid (m. 42°, 58°, and 68°) are known to exist. All samples of the double acid (consisting of equal parts of the allo- and *n*-acids) sintered at 56° and m. about 90°. Analyses of the double acid were carried out by a method described in C. A. 6, 2746.

LOUIS E. WISE.

**Hydrindene-1,2-diol(1,2-hydroxyindane).** J. BÖRSEKEN AND CHR. VAN LOON. *Proc. Acad. Sci. Amsterdam* 20, 1186-91(1918).—B. and v. L. have synthesized the *cis* and *trans*-1,2-hydroxyindanes (A) and (B), resp. (cf. Heusler and Schieffer, *Ber.* 32, 28(1899) and Weizberger *Ber.* 44, 1436(1911)). (A), felted needles (from  $C_6H_6$ ), sintering 105.5°, m. 107.5-8°, was prepd. by oxidizing an aq. indene emulsion with  $KMnO_4$ . The yield was 13% of the theoretical. (B) was formed by boiling indene dibromide with AcOK in AcOH, isolating the diacetate of (B), b<sub>12</sub> 169-9.5,  $d_{20}^{20}$  1.1771,

$n_D^{20}$  1.5170, and sapon. the latter with aq. KOH. (B), after sublimation *in vacuo*, and recrystn. from PhMe was obtained as leaflets, m. 159.8–60.0°. The *dibenzoate* of (A) m. 109.5–10.5°; the *dibenzoate* of (B), m. 76.5–77.5°. The *diphenylurethan* of (A), m. 205° (decompn.); that of (B), m. 206.5°. All derivs. of (B) on sapon. were reconverted into (B). The *cis*-compds. (derived from (A)) on sapon. yielded a new *diol* (C), m. 100.5–101.5°, even after recrystn. and sublimation. (C) appears to be a polymorphic modification of (A), since a mixt. of (C) and (A), m. 107.5–108°. The configurations of (A) and (B) were detd. by B.'s boric acid-conductivity method (C. A. 6, 623).

*Indene oxide* (D),  $C_9H_8CH_2CH=CH_2$ , rhombic plates, m. 31–31.5°,  $n_D^{20}$  1.1258,  $n_D^{25}$  1.5627, was formed in nearly theoretical yield, by treating indene bromohydrin in  $Et_2O$  with powdered KOH. Attempts to obtain (D) from the iodohydrin proved unsatisfactory. By boiling (A), (B), or (D) with aq.  $H_2SO_4$ ,  $\beta$ -indanone (E), m. 57–8°, was obtained. Isomerization of (D) to (E) also takes place when  $H_2O$  is absent (in dry  $Et_2O$  by means of  $ZnCl_2$ ). (D) may be hydrated under proper conditions (very dil. acid?), yielding a mixt. of (A) and (B), indicating that a partial change of configuration has taken place. Under most conditions, however, hydration of (D) resulted in the formation of an insol. compd., together with some (E).

LOUIS E. WISE.

**Synthesis of isobrazilein and certain related anhydropyranol salts. I. HERBERT GRACE CRABTREE AND ROBERT ROBINSON. Univ. Liverpool. *J. Chem. Soc.* 113, 859–80(1918).**—Hitherto no deriv. of brazilein (I) has been synthesized containing the characteristic fused ring system. (I) may be oxidized to the quinone brazilein (II), which is converted by mineral acid into the isobrazilein salts (III) (Hummel and A. G. Perkin, *J. Chem. Soc.* 41, 367(1882); Engels, P., and R., *C. A.* 2, 3064). Derivs. of the tri-Me ether of (III) (A) have now been synthesized. *Preliminary expts.*: Friedländer's process (*Ber.* 28, 1946(1895)) for the prepn. of 2-AcC<sub>10</sub>H<sub>7</sub>OH was modified as follows: An intimate mixt. of 50 g.  $\alpha$ -C<sub>10</sub>H<sub>7</sub>OH, 75 g. HOAc, and 75 g.  $ZnCl_2$  was heated 0.5 hr. at 160–70°, treated with  $H_2O$ , and the ppt. washed with dil. HCl, dried, and recrystd. 3 times from MeOH, when it was pure enough for the next step, the synthesis of 3,4-CH<sub>2</sub>O<sub>2</sub>C<sub>6</sub>H<sub>5</sub>CH:CHCOC<sub>10</sub>H<sub>7</sub>OH (B) (Kostanecki, *Ber.* 31, 707(1898)). 10 g. of this were dissolved in 600 cc. hot alc., treated with 80 cc. concd. HCl and 240

cc.  $\text{H}_2\text{O}$ , and boiled under reflux for 24 hrs.; on cooling, the flavonone, 3',4'-methylene-dioxy-2-phenyl-2,3-dihydro-1,4- $\alpha$ -naphthopyrone (IV) sepd., colorless needles after recrystg. from alc.-HCl and then twice from alc., m.  $145^\circ$ , easily reconverted into (B) by NaOH; let stand overnight with 3,4- $\text{CH}_2\text{O}_2\text{C}_6\text{H}_4\text{CHO}$  in HOAc after satg. with HCl gas it gives the *piperonylidene derivative*, golden needles, m.  $206^\circ$ , gives a reddish purple color in  $\text{H}_2\text{SO}_4$  and yields dark green condensation products of unknown constitution when treated with vigorous acid condensing agents. 10 g. 2,4-(HO) $_2$ C $_6$ H $_3$ COCH $_2$ -CH $_2$ Ph (C) were mixed with 15 g. fused NaOAc and 20 g.  $\text{Ac}_2\text{O}$  and heated 4 hrs. in an oil bath at  $170^\circ$ , followed by cooling, addition of  $\text{H}_2\text{O}$  and dil. HCl; the resulting *acetyl derivative*, C $_{19}$ H $_{16}$ O $_4$ , needles from MeOH, m.  $121^\circ$ , dissolves in  $\text{H}_2\text{SO}_4$  to a faintly yellow soln. which fluoresces violet on heating, is not changed by dil. aq. NaOH, but on boiling 2.5 hrs. with excess dil. aq.  $\text{Na}_2\text{CO}_3$  it is hydrolyzed and dissolves, 7-hydroxy-3-benzyl-2-methyl-1,4-benzopyrone sepg., needles from alc., m.  $282^\circ$ , shows a violet fluorescence in alk. soln. or on heating the soln. in  $\text{H}_2\text{SO}_4$ ; when 2 g. were dissolved in hot MeOH and boiled with 5 cc.  $\text{Me}_2\text{SO}_4$ , adding 10 cc. 40% aq. KOH during 5 min., pptg. with  $\text{H}_2\text{O}$ , taking up in Et $_2\text{O}$  and washing the soln. with dil. NaOH, the *methyl ether* (D) was obtained, needles from MeOH, m.  $109^\circ$ , sol. in  $\text{H}_2\text{SO}_4$  with a faint blue fluorescence which increases on standing or warming gently, the effect apparently being due to sulfonation and not to the formation of a pyrrylium salt containing the indene nucleus. 1.5 g. (D), 2 g. KOH, and 10 cc. MeOH were heated in a wide test tube, allowing part of the MeOH to distil off. After the 1st red color had changed to yellow the residue and distillate were distd. with steam,  $\text{AcCH}_2\text{CH}_2\text{Ph}$  passing over; its semicarbazone m.  $145^\circ$ , not  $142^\circ$  (Klages, *Ber.* 37, 2323(1904)); the residual liquid was acidified with HCl, and made alk. with  $\text{Na}_2\text{CO}_3$ , 2,4-HO(MeO)C $_6$ H $_3$ COCH $_2$ CH $_2$ Ph (a, see below) pptg. The aq. soln. from this was extd. with Et $_2\text{O}$ , concd., and acidified, yielding 2,4-HO(MeO)C $_6$ H $_3$ CO $_2$ H, these products proving the structure of (D). Methylation of 2,4-(HO) $_2$ C $_6$ H $_3$ Ac to paeanol (E) cannot be satisfactorily carried out with  $\text{Me}_2\text{SO}_4$ , the di-MeO ether (F) being the main product; the best method is to use 1.1 mols. of MeI and KOH in boiling MeOH soln. If 3 mols. MeI and KOH are used the isomeric di-Me deriv. (G), containing 1 of the Me groups in the aromatic nucleus is formed. Attempts to obtain (G) from (E) and 2 mols. of MeI and KOH gave mainly unchanged (E); the small portion insol. in cold dil. aq. NaOH was a mixt. of (F), insol., and (G), sol. in warm dil. NaOH. It thus appears that in using 3 mols. MeI and KOH originally C-methylation preceded O-methylation. The presence or absence of the nuclear Me group in derivs. of the type of 2,4-(HO) $_2$ C $_6$ H $_3$ CO $_2$ H or resorcylic ketone derivs. may be detd. by the formation of homofluorescein, or fluorescein, resp. The substance is strongly heated with o-C $_6$ H $_4$ (CO) $_2$ O and a few drops  $\text{H}_2\text{SO}_4$  and the product dissolved in dil. NaOH. Under these conditions fluorescein is formed even from the ethers of m-C $_6$ H $_4$ (OH) $_2$ . However, if the nucleus is alkylated the alk. soln. is intense cherry-red, and the fluorescence is less persistent on diln. Bargellini and Marantonio (*C. A.* 3, 170) describe a monomethyl ether of (C), m.  $74-5^\circ$  and a di-Me ether, m.  $103-4^\circ$ . C. and R. were unable to isolate the former, while the latter turned out to be the actual mono-Me ether, 2-hydroxy-4-methoxyphenyl phenylethyl ketone (a, see above), needles, m.  $105^\circ$ , which may also be prepd. by using 0.5 the calcd. amt.  $\text{Me}_2\text{SO}_4$  or by using MeI; it dissolves in hot aq. NaOH and in alc. soln. gives a red-violet color with  $\text{FeCl}_3$ ; could not be converted into a definite Ac or Bz deriv. or Me ether. The structure of (a) is proved by the following method of prepn.: 5 g. benzylidenepaeanol (b) were dissolved in 250 cc. alc. at  $50-60^\circ$ , the air in the flask expelled by H, and treated with 15 cc. each of 1% solns. of  $\text{PdCl}_2$  and gum arabic. Reduction proceeded rapidly on shaking with H, the concd. soln. yielding (a). An attempt to prep. the di-MeO homolog of (C) by condensing m-C $_6$ H $_4$ (OH) $_2$  with 3,4-(MeO) $_2$ C $_6$ H $_3$ CH $_2$ CH $_2$ CO $_2$ H (H) with

the corresponding pyranol anhydrochloride, *7-methoxy-2-phenyl-1,4-benzopyranol anhydrochloride*, was obtained by satg. 8 g. 2,4-HO(MeO) $C_6H_3$ CHO and 6 g. AcPh in 25 cc. HOAc with HCl gas for 1.5 hrs., pptg. more of the orange needles with Et<sub>2</sub>O; seps. from dil. HCl with 3 H<sub>2</sub>O, m. 102–3°, shows a blue-green, persistent fluorescence in aq. soln. (*L*) was treated in hot PhH with PhMgBr in Et<sub>2</sub>O until a test gave an intense blue-green color with an Et<sub>2</sub>O soln. of *p*-C<sub>6</sub>H<sub>4</sub>O<sub>2</sub>. After heating 10 min. on the H<sub>2</sub>O bath, cooling, and decompg. with H<sub>2</sub>O, the PhH soln. contained a substance which was probably the  $\alpha$ -pyranol (*V*) and was isolated as the *anhydroferrichloride* (*M*), orange needles from HOAc, m. 185°, by shaking with dil. HCl and adding concd. FeCl<sub>3</sub> soln. to the aq. layer. (*M*) is also obtained from 7-methoxyflavone and PhMgBr, through the carbinol base (*VI*), this indicating that the same anhydro-salt may correspond to 2 carbinol bases. (*M*) was also formed from 7-hydroxy-2,4-diphenyl-1,4-benzopyrano dimethyl ether (*N*), which loses MeOH when treated with acids. (*VI*) was prepd. by condensing Bz<sub>2</sub>CH<sub>2</sub> with *m*-MeOC<sub>6</sub>H<sub>4</sub>OH in H<sub>2</sub>SO<sub>4</sub>, but could not be freed from a portion that became demethylated in the synthesis. However, when (*N*) is dissolved in dil. HCl and the soln. treated with NaOAc, amorphous *7-methoxy-2,4-diphenyl-1,4-benzopyranol* (*VI*), is pptd., m. 55–7°; in Et<sub>2</sub>O with dry HCl it yields the *anhydrodihydrochloride*, yellow crystals with 2 H<sub>2</sub>O, m. 121°; when dissolved in hot dil. HCl the *anhydrohydrochloride* seps., red needles, m. about 80°; *anhydrochloroplatinate*, orange needles from the hot soln., m. 224°. Appendix II. Describes the synthesis of *7-hydroxy-4,3-indeno-1,2-benzopyrone* (*VII*), the 1st synthetic compd. containing the skeleton of braziliin and hematoxilin, with J. A. Prescott in 1911.

After frequent shaking during 2 hrs. CO<sub>2</sub> was passed through the soln. of the Na deriv. from 8.5 g.  $\alpha$ -hydrindone (*P*) and 6 g. NaNH<sub>2</sub> until most of the Et<sub>2</sub>O had evapd. After careful addition of ice the soln. was extd. twice with Et<sub>2</sub>O to remove unchanged (*P*), acidified with HCl, cooling with ice, and the ppt. quickly collected and dried on porous tile, 8 g. *1-hydrindone-2-carboxylic acid* being obtained, crystals, gives a red-violet color with FeCl<sub>3</sub>, slowly decomp. into (*P*) and CO<sub>2</sub> at room temp. or rapidly on warming with H<sub>2</sub>O; mixed with 9 g. *m*-C<sub>6</sub>H<sub>4</sub>(OH)<sub>2</sub> and 100 cc. satd. HCl-MeOH, let stand 2.5 days, then heated 2 hrs. on the H<sub>2</sub>O bath and cooled, it gave 3 g. (*VII*), needles from alc., darkens about 230°, turns dark blue 280°, but does not m., fluoresces intensely blue-violet in H<sub>2</sub>SO<sub>4</sub>.

M. HEIDELBERGER.

**Trimorphic change of 4-nitroaceto-*o*-toluidide.** FREDERICK DANIEL CHATTAWAY: Oxford. *J. Chem. Soc.* 113, 897–9(1918).—In general anilides cryst. in 1 of 3 forms:  $\alpha$ , slender prismatic;  $\beta$ , compact; or  $\gamma$ , hair-like, and many have been obtained in 2 of these. 2,4-AcNH(O<sub>2</sub>N) $C_6H_3$ Me (*A*) (Nölting and Collin, *Ber.* 17, 269(1884)) can be obtained in all 3. From a soln. in boiling alc. the faintly yellow, bulky  $\alpha$ -form seps. as doubly refracting needles with straight extinction; if let stand in the mother liquor they gradually change to small, yellow, less voluminous, hexagonal monoclinic plates of the  $\beta$ -form, the change taking a few days when the vessel is undisturbed. Often before the transformation is complete the  $\gamma$ -form begins to appear as colorless tufts of minute, doubly refracting, hair-like crystals (extinction, 35°) until the whole contents of the vessel become a felted mass which is difficultly filterable. If the mass

of  $\alpha$ -form first sepg. is seeded with the  $\gamma$ -form direct transformation occurs without the  $\beta$ -form as intermediate stage. All 3 forms m.  $150-1^\circ$ . A detailed crystallographic report by T. V. Barker is appended.

M. HEIDELBERGER.

**Preparation of ethylamine and of diethylamine.** EMIL ALPHONSE WERNER. Trinity Coll., Dublin. *J. Chem. Soc.* 113, 899-902 (1918).—9 g.  $\text{EtNH}_2$  were added to 12 g.  $\text{Et}_2\text{NH}\cdot\text{HCl}$  in 30 cc. alc. and after 1 hr. all free amine was removed by distn. and converted into the HCl salt; this proved to be pure  $\text{Et}_2\text{NH}\cdot\text{HCl}$ . Similarly, 8 g.  $\text{Et}_2\text{NH}$ , added to 15 g.  $\text{Et}_2\text{N}\cdot\text{HCl}$  in 35 cc. alc. gave a distillate which yielded pure  $\text{Et}_2\text{N}\cdot\text{HCl}$ . It is thus seen that, contrary to the usually accepted view, the strength of the bases decreases in the order  $\text{EtNH}_2$ ,  $\text{Et}_2\text{NH}$ ,  $\text{Et}_2\text{N}$ . A fair sepn. of the 3 amines was obtained as follows: 4 g. NaOH were added to a soln. of 13.8 g.  $\text{Et}_2\text{N}\cdot\text{HCl}$ , 11 g.  $\text{Et}_2\text{NH}\cdot\text{HCl}$ , and 9 g.  $\text{EtNH}_2\cdot\text{HCl}$  in 60 cc.  $\text{H}_2\text{O}$ , the soln. was well shaken, and the liberated amine distd. off after 20 hrs., the distillate yielding practically pure  $\text{Et}_2\text{N}\cdot\text{HCl}$  (Cl, 26.04%). The remaining soln. was treated similarly after adding 4 g. more NaOH, the resulting salt (Cl, 34.44%) consisting of about 85%  $\text{Et}_2\text{NH}\cdot\text{HCl}$  and 15%  $\text{EtNH}_2\cdot\text{HCl}$ . The residual soln. was directly distd. after again adding NaOH, the liberated amine having the approx. compn.,  $\text{EtNH}_2$ , 75%;  $\text{Et}_2\text{NH}$ , 25%. Usually, in the prepn. of  $\text{EtNH}_2$  the entire amt. of  $\text{EtBr}$  used is added to the  $\text{NH}_3$  at once, but that this is an erroneous procedure is shown by the figures below, in which the mol. ratio  $\text{EtBr}:\text{NH}_3$  and the % yield  $\text{EtNH}_2$  are given, resp.: 1:1, 11.3; 1:4, 24.4; 1:6, 26.7; 1:8, 28.1; 1:16, 34.2. Based on the above expts., bearing in mind the relative tendency to "dissociation" of the resp. amine salts, the following procedure for the prepn. of  $\text{EtNH}_2$  was worked out: 5 l. 90% alc. were satd. with  $\text{NH}_3$  (cf. C. A. 13, 121) until 490 g. had been dissolved, 200 g.  $\text{EtBr}$  were added, and then, at intervals of 2 days, 180, 170, 150, 130, 110, 100, 80, and 66 g.  $\text{EtBr}$ , resp. On the 12th day  $\text{NH}_4\text{Br}$  began to sepd., and on the 16th day the prepn. was stopped. Alc. containing 10%  $\text{H}_2\text{O}$  was used since it was found that when much  $\text{NH}_4\text{Br}$  sepd. early in the process the subsequent formation of  $\text{Et}_2\text{N}$  was promoted. The  $\text{NH}_4\text{Br}$  was sepd. and the alc. soln. concd. by distn. (using the evolved  $\text{NH}_3$  to charge more alc.) until nearly all  $\text{NH}_4\text{Br}$  formed had sepd., 362 g. in all being obtained. The soln. of the amine hydrobromides was then distd. until the temp. reached  $130^\circ$  to remove all alc. If it is not convenient to liberate the entire amt. of mixed amines by addition of NaOH to the residue  $\text{CHCl}_3$  may be used for their sepn., 0.163 g.  $\text{EtNH}_2\cdot\text{HBr}$  dissolving in 100 cc. at  $14^\circ$ , while 42 g.  $\text{Et}_2\text{NH}\cdot\text{HBr}$  dissolve. In this way 465 g. pure  $\text{EtNH}_2\cdot\text{HBr}$  and 510 g.  $\text{Et}_2\text{NH}\cdot\text{HBr}$  containing a little more than 5%  $\text{Et}_2\text{N}\cdot\text{HBr}$  were obtained. After sepn. of  $\text{Et}_2\text{N}$  (14 g.) by the calcd. amt. NaOH, 226 g.  $\text{Et}_2\text{NH}$ , b.  $56-7.5^\circ$ , were obtained. It is thus seen that the amt. of  $\text{Et}_2\text{N}$  formed is practically negligible, whereas it has hitherto been the chief product of the reaction (Garner and Tyrer, C. A. 10, 1328).

M. HEIDELBERGER.

**A new synthetic method of passing from aliphatic to aromatic compounds.** TEL. KOMNINOS. Univ. Athens. *Compt. rend.* 167, 781-3 (1918); *Bull. soc. chim.* 23, 449-55 (1918).—To 28 g.  $\text{CH}_3(\text{COCl})$  and 11.5 g.  $\text{Me}_2\text{CO}$  was added 20 g.  $\text{CaCO}_3$ . A temp. elevation and vigorous evolution of  $\text{HCl}$  necessitated cooling the soln. More  $\text{Me}_2\text{CO}$  was added after the reaction had ceased. Upon standing brilliant vermilion crystals sepd. The  $\text{CaCO}_3$ , filtered off, washed with  $\text{Me}_2\text{CO}$ , and dried, weighed 15 g. though theoretically 10 g. should have been used up by the reaction. The crystals washed with  $\text{Me}_2\text{CO}$ , alc., then  $\text{Et}_2\text{O}$ , and dried, weighed 14 g. The filtrate was made alk., evapd. to dryness and the residue taken up in boiling abs. alc. and evapd. to dryness. This was repeated, using  $\text{H}_2\text{O}$ . After treating with  $\text{Et}_2\text{O}$ , 1 g. of crystals was obtained, m. p.  $217^\circ$ , identical with that of phloroglucinol. The vermilion crystals (decomp.  $160^\circ$ ) are sol. in  $\text{Me}_2\text{CO}$ , insol. in  $\text{Et}_2\text{O}$  and alc., and the hot  $\text{H}_2\text{O}$  soln. contains Cl but gives no phloroglucinol reaction. The formula  $\text{ClCOCH}_2\text{COCH}_2\text{COME}$

(Cl obtained, 21.8%; theory, 21.84%) represents this compd. and explains why only 1 mol. of HCl was liberated in the primary reaction. To transform this compd. into phloroglucinol, 5 g. in  $H_2O$  was heated with 5 g.  $CaCO_3$  on a boiling  $H_2O$  bath.  $CO_2$  was liberated and the  $CaCO_3$  loss, detd. as before, was 1.5 g., corresponding to 1 mol. HCl. From the yellow filtrate about 4 g.  $C_6H_4O_3$ , m.  $217^\circ$ , was obtained by crystn. from  $Et_2O$ . The two compds. produced by this synthesis are  $ClCOCH_2COCH_2COMe$  and  $C_6H_4O_3$ , the former produced by a secondary reaction but being easily converted into the latter by loss of HCl. The compn. of phloroglucinol as a tautomeric compd. is confirmed. A review is given of the methods of passing from the aliphatic to the aromatic series.

C. H. KIDWELL.

**Phenols.** The fusion of sodium hydroxide with several phenols and sulfonic acids. MAITLAND C. BOSWELL AND J. V. DICKSON. Univ. Toronto. *J. Am. Chem. Soc.* 40, 1786-93 (1918).—Following up a previously advanced hypothesis (*C. A.* 13, 98), that in fusions of NaOH with certain salts oxidations occur whose mechanism would consist of a decompn. of  $H_2O$ , fusions of NaOH were made with the Na salts of  $PhSO_3H$ ,  $\beta$ - $C_{10}H_7SO_3H$ , anthraquinone- $\beta$ -monosulfonic acid, phenylglycine- $o$ -carboxylic acid and of the 7 phenols, carboic acid, quinol, pyrocatechol, resorcinol, pyrogallol, hydroxyquinol and phloroglucinol. Fusions were carried out both with access to the air and in an atm. of N. From a table given showing analytical results of the gases formed during the reactions, it is seen that the proportion of  $O_2$  used up to  $H_2$  produced is approx. 1:2. The yield of PhOH by fusion of  $PhSO_3Na$  with NaOH was increased from 90.6% to 99% by carrying out the fusion and cooling of the melt in an atm. free from gaseous  $O_2$ . When free  $O_2$  was present secondary reactions occurred, involving first an absorption of free  $O_2$  followed by an oxidation involving the elements of  $H_2O$ , free  $H_2$  being evolved. None of the 6 di- and trihydroxybenzenes were the direct cause of this  $H_2$  evolution.  $PhONa$  and  $NaHSO_3$ , products in the sulfonate fusion, were practically unacted on by NaOH. Oxidation of the 3 dihydroxybenzenes and of pyrogallol by NaOH occurred in the presence of free  $O_2$  but oxidation by reaction with  $H_2O$  catalyzed by NaOH was not observed in this case nor in the fusion of  $\beta$ - $C_{10}H_7SO_3Na$  or Na phenylglycine- $o$ -carboxylate with NaOH. In the fusion of Na anthraquinone- $\beta$ -monosulfonate, oxidation occurs by means of the  $H_2O$  reaction without necessity of previous oxidation by free  $O_2$ .

C. H. KIDWELL.

Some ketones of camphor. HANS RUPE, MARKUS WERDER and KUNHIKO TOKAGI. *Helvetica chim. acta* 1, 309-42 (1918).—Camphorylidene-3-acetone (A),  $C_9H_{14}.CO.C:CHAc$ , was prepd. by allowing the camphorylidene-3-acetyl chloride to

react with  $CHNaCO_2Et_3$ , obtaining first the intermediate compd. diethyl di[camphorylidene-3-acetyl]malonate (B), yellow needles, m.  $90-1^\circ$ , from which (A) was obtained by hydrolysis in AcOH with 30%  $H_2SO_4$ . (A) is a yellow liquid,  $b_{10}$   $137-8^\circ$ ,  $d_4^{20}$  1.0327. Several derivs. of (A) were prepd. Benzylidene-camphorylidene-3-acetone, m.  $94-5^\circ$ ; *p*-nitrobenzylidene-camphorylidene-3-acetone, small yellow crystals, m.  $150-1^\circ$ ; an oxime, white needles, m.  $142-3^\circ$ ; a phenylhydrazone, orange needles, m.  $145-6^\circ$ ; an hydrazine deriv. of camphorylidene-3-acetone, long, yellow needles, m.  $112-3^\circ$ ; a semicarbazone, prismatic needles which decomp.  $223-4^\circ$ . Repeated attempts were made to regenerate (A) from its semicarbazone but were not successful. No  $NaHSO_3$  compd. of (A) could be obtained. A second ketone, camphoryl-3-acetone  $C_9H_{14}.CO.CHCH_2Ac$

(C), a reduction product of (A), was also obtained through the malonic ester syntheses. Instead, however, of using camphorylidene-3-acetyl chloride, as in the prepn. of (A), camphoryl-3-acetyl chloride was used. (C) is a yellow oil  $b_{12}$   $150-1^\circ$ . However, when regenerated from its semicarbazone it is an odorless oil, of bitter taste,  $b_{12}$   $148.5-9^\circ$ ,

$d_{40}^{20}$  1.0213. Several derivs. of this ketone were prepd.: *Benzal-camphoryl-3-acetone*, white plates, m. 75–6; a *semicarbazone*, long, colorless needles, m. 203–4°; a *phenylhydrazone*, colorless needles, m. 87–9°. (C) also forms a compd. with acetophenone, namely, *camphoryl-3-acetophenone* (D),  $C_{18}H_{24}.CO.CHCH_3.COCH_2.Bz$ . This was puri-

fied through its Cu salt, which seps. out as light green crystals, m. 184–6°. (D) crysts. out in the form of prisms, m. 59–61°. In connection with the prepn. of (A) and (C) the following new compds. were prepd.: *Camphorylidene-3-acetyl chloride*, colorless needles, m. 34–5°; *camphorylidene-3-acetic acid hydrobromide*, colorless needles, m. 153–4° (decompn.); a *bromine derivative of camphorylidene-3-acetic acid*, colorless needles, m. 73–5°; *ethyl camphorylidene-3-acetate*, yellow oil, odorless,  $b_{12}$  149.5–50°,  $d_{40}^{20}$  1.0459; *camphoryl-3-acetic acid*, oil,  $b_{12}$  191.5–2.5°, which crysts. on standing, m. 83–4°; *ethyl camphoryl-3-acetate*, oil,  $b_{12}$  154–5°; *anhydride of camphoryl-3-acetic acid and acetic acid*  $C_8H_{14}.CO.CHCH_3.COOAc$ , colorless needles, m. 118–20°; *ethyl di-[camphorylidene-3-*

*acetyl]acetate*, colorless, needles, m. 149–50°. An improved method for the prepn. of *camphorylidene-3-acetic acid* (cf. *Ann.* 281, 387) is described. MAX PHILLIPS.

**Direct transformation of acid chlorides into nitriles by means of a catalyzer.** ALPH. MAILHE. *Bull. soc. chim.* 23, 380–1 (1918).—A simple method for directly converting an acid chloride into its corresponding nitrile consists in passing the vapors of the acid chloride and gaseous  $NH_3$  over  $Al_2O_3$  heated to 490–500°.  $BzCl$  when thus heated yields  $PhCN$ , b. 188–90°; isovaleryl chloride gives isovaleronitrile, b. 128–9°; isobutyryl chloride and propionyl chloride yield their corresponding nitriles, b. 108° and 92°, resp. MAX PHILLIPS.

**Alkaloids of the pomegranate tree. V. Separation of pelletierine and methylisopelletierine into their optical isomers. Explanation of Tanret bases.** KURT HESS AND ANNALIESE EICHEL. *Ber.* 51, 741–7 (1918); cf. *C. A.* 12, 1186.—The authors mention the previous works on the constitution of pelletierine (a) and methylisopelletierine (b). Both are optically inactive. Tanret described two optically active varieties of identical compn. H. and E. believed that these varieties were the optical isomers of (a) and (b). Tanret found  $[\alpha]_D -30^\circ$  (sulfate) for the isomer of (a) and  $[\alpha]_D 23^\circ$  (hydrochloride) for the isomer of (b). (a) is easily sepd. through the bitartrate. *d*-Pelletierine *d*-tartrate shows  $[\alpha]_{\text{Gaslight}}^{21}$  19.50 and *l*-pelletierine *l*-tartrate  $[\alpha]_{\text{Gaslight}}^{20} -19.62^\circ$ . In the prepn. of the free optically active bases from these salts a rapid racemization was observed when these salts were decompd. with alkalis at 0° and distd. *in vacuo*. The authors established that this racemization was the result not of the action of the alkalis but of the distn. When the bitartrate was treated with alkali according to the method above mentioned, then shaken with ether and treated with  $H_2SO_4$  the aq. soln. contained the corresponding optically active bases and the following results were obtained: *d*-Pelletierine sulfate gave  $[\alpha]_{\text{Gaslight}}^{18}$  5.39°, and *l*-pelletierine sulfate  $[\alpha]_{\text{Gaslight}}^{18} -5.33^\circ$ . In comparison with T.'s results for "optically active pelletierine"  $[\alpha]_D -30^\circ$  (sulfate), it is concluded that no *l*-pelletierine exists in the optically active substance of Tanret. (b) gives for *d*-methylisopelletierine *d*-bitartrate  $[\alpha]_{\text{Gaslight}}^{20}$  19.15°, and for *l*-methylisopelletierine *l*-bitartrate  $[\alpha]_{\text{Gaslight}}^{18} -19.37^\circ$ . For the sulfate of the active base  $[\alpha]_{\text{Gaslight}}^{18}$  6.71° and  $[\alpha]_{\text{Gaslight}}^{18} -6.70^\circ$ . For the hydrochloride  $[\alpha]_{\text{Gaslight}}^{18}$  9.90° and  $[\alpha]_{\text{Gaslight}}^{18} -9.69^\circ$ . The comparison with  $[\alpha]_D 23^\circ$  (hydrochloride) given by Tanret shows that Tanret's substance is quite different from (b). The authors observe also that the optically active forms of their bases do not exist in *Punica granatum*. Contrary to (a), the optically active forms of (b) do not racemize during distn. and the O atom in the

neighborhood of the asym. C atom of (b), differing from the *o*-atom in the  $\gamma$ -position of (a), has no influence on the asym. C atom. MARCEL J. SIMONET.

**Cleavage of digitonin cholesteride.** A. WINDAUS. *Z. physiol. Chem.* 101, 276-7; *J. Chem. Soc.* 114, II, 336; cf. Lifschütz, *C. A.* 12, 2086.—W. gives further details of the method for the prepn. of cholesteryl acetate from digitonin cholesteride, but points out that the cleavage is more readily accomplished by the action of hot xylene (cf. *C. A.* 4, 2311) or by one of the more recent methods, involving the use of  $\text{Ac}_2\text{O}$ . Cf. Prescher, *C. A.* 12, 97. C. J. WEST.

**Determination of the configuration of cis-trans isomeric substances.** J. BÖRSEKEN AND C. VAN LOON. *Proc. Acad. Sci. Amsterdam* 21, 80-9 (1918).—A translation into English of the paper abstracted in *C. A.* 12, 2545. E. H.

**Addition of hydrogen bromide to allyl bromide.** A. F. HOLLEMAN AND B. F. H. J. MATHES. *Proc. Acad. Sci. Amsterdam* 21, 90-1 (1918).—A translation into English of the paper abstracted in *C. A.* 12, 2545. E. H.

**Xanthic acids and the kinetics of their decomposition** (VON HALBAN, HECHT) 2. **Constituents of resins** (LIEB, ZINKER) 26. **Preparation and properties of aniline chlorostannate** (DRUCKER) 6.

**Chlorinating methane.** B. S. LACY. U. S. 1,286,353, Dec. 3.  $\text{Cl}$  is mixed with 5 times its vol. of  $\text{CH}_4$  at ordinary temp. and 10 volumes of  $\text{CH}_4$  separately heated to  $370^\circ$  and mixed with the cold  $\text{Cl-CH}_4$  mixt. and reaction is effected at a temp. of about  $450^\circ$  in a vessel of  $\text{Cl}$ -resisting material protected against loss of heat by radiation. This procedure effects the production of  $\text{CH}_2\text{Cl}$  with a smaller amt. of  $\text{CH}_2\text{Cl}_2$ .

**Acetic acid.** H. DREYFUS. U. S. 1,286,255, Dec. 3.  $\text{HOAc}$  is made by passing a mixt. of acetaldehyde with  $\text{O}$  or air over a catalyst such as platinized asbestos at a temp. between the b. p. of  $\text{HOAc}$  and  $400^\circ$ . U. S. 1,286,256 specifies conducting the same process within a temp. range of  $150$ – $250^\circ$ , which gives best yields. Preferably the temp. is held at  $150$ – $200^\circ$ .  $\text{Cu}$  or oxides of  $\text{Cu}$  or  $\text{Cr}$  also may be used as catalyst.

**Acetic acid from acetaldehyde.** BADISCHE. Ger. 296,282, addition to 294,724, 1917 (*C. A.* 11, 2580). Instead of  $\text{Fe}$  compds., such substances as  $\text{Ni}(\text{OAc})_2$  or animal charcoal may be used as catalysts.

**Aromatic stibinic acids.** CHEM. FABRIK VON HEYDEN, AKT.-GES. Ger. 296,940; with 261,825 and 269,255, addition to 254,421, 1917. Nitro derivs. of aromatic stibinic acids are prepd. by treating diazotized nitroamines with antimonites or antimonious acid, in acid or neutral solns., at low temps.  $\text{Sb}_2\text{O}_3$  dissolved in such an acid as tartaric acid is recommended, and  $\text{Cu}$  powder is often useful as a catalyst. 2-Nitro- and 2,4-dinitrophenylstibinic acids are brown powders which explode on heating. 3-Nitro-*p*-anilinoarsonic acid yields 2-nitro-4-arsonophenylstibinic acid,  $\text{AsO}_2\text{H}_2\cdot\text{C}_6\text{H}_4(\text{NO}_2)\cdot\text{SbO}_2\text{H}_2$ , which is a similar brown powder.

**Halogenated arsonic acids.** BAYER & Co. Ger. 296,915, 1917. Hydrocarbons of the acetylene series are treated with  $\text{As}$  trihalides, or mixts. which yield these compds. and the products are converted into arsenoxides and then into arsonic acids by oxidation. Thus, heptinene gives "heptinenechloroarsenoxide," a dark sirup, and "heptinenechloroarsenic acid" ( $\text{C}_6\text{H}_{11}\cdot\text{CCl}:\text{CH}\cdot\text{AsO}(\text{OH})_2$ ), white needles, m.  $115^\circ$ , the Na salt of which is freely sol. in  $\text{H}_2\text{O}$ . Octinene yields "octinenebromoarsenoxide" and "octinenebromoarsenic acid," m.  $129$ – $30^\circ$ .

**6-Amino-3-sulfobenzoic acid.** BAYER & Co. Ger. 296,941, 1917. Anthranilic acid is directly sulfonated by means of chlorosulfonic acid in an indifferent solvent, such as nitrobenzene, dichlorobenzene, or petroleum.

***ω*-Dihalo-*p*-toluyl-*o*-benzoic acid.** CHEM. FABRIK GRIESHEIM-ELEKTRON. Ger. 297,018, 1917. When 2-*p*-toluylbenzoic acid is treated with Br at a high temp., it is smoothly converted into 2-*ω*-dibromo-*p*-toluylbenzoic acid (4-dibromomethyl-2'-carboxybenzophenone), a white powder, valuable as a source of anthraquinone derivs., which changes into 4-aldehydo-2'-carboxybenzophenone (2-*p*-aldehydobenzoylbenzoic acid) on heating with dil. alkali hydroxide.

**Crystalline ester of the diiodide of ricinistearolic acid.** J. D. RIEDEL. Ger. 303,052, 1914. Et ricinistearolate diiodide, colorless needles, m. 31°, can be obtained by esterifying the diiodide of ricinistearolic acid or by the addition of I to Et ricinistearolate.

**Single or mixed anhydrides of monobasic carboxylic acids.** NAAMLOOZE VENNOOTSCHAP FABRIEK VAN CHEM. PRODUCTEN. Holl. 2,484, May 15, 1918. Anhydrous alkali or alk.-earth salts of sulfuric and carboxylic acids are heated, alone or in the presence of an indifferent liquid, and the single acid anhydride is distd. off.

**Dialdehydesulfoxylic acids.** A. BINZ. Ger. 303,478, 1916. Diformaldehydesulfoxylic acid,  $S(OCH_2OH)_2$ , can be obtained from a formaldehydesulfoxylate, formaldehyde soln., and alc. HCl; similarly, dibenzaldehydesulfoxylic acid is obtainable from benzaldehydesulfoxylate. The analogous formaldehydebenzaldehydesulfoxylic acid,  $HOCH_2OSOCHPhOH$ , reacts with *p*-toluidine, yielding the substance  $MeC_6H_4NHCH_2OSOCHPhOH$ .

***p*-Cymenesulfonic acid.** RHEINISCHE CAMPHER-FABRIK. Ger. 303,095, 1916. 2-Bromo-*p*-cymene-3-sulfonic acid can be conveniently reduced by heating with ordinary or activated Zn and NaOH soln.

**Tropic acid.** CHEM. WERKE GRENZACH. Ger. 302,737, 1917. Ethylhydroxy-methylenphenylacetate is reduced to Et tropate and hydrolyzed, the resulting tropic acid being identical with the product obtained from atropine.

**Aromatic selenium compounds.** FARBW. VORM. M. L. & B. Ger. 299,510, 1917. Organic Se compds. can be prep'd. by treating such substances as aniline, acetanilide, phenol, salicylic acid, and nitrophenol with a soln. of Se or  $SeO_2$  in  $H_2SO_4$  at low temp. The product from acetanilide forms colorless crystals, m. approx. 260°; colorless products were also obtained from phenol, salicylic acid, and resorcinolarsonic acid, whereas aniline sulfate yielded an almost black powder and *o*- and *p*-nitrophenols yellow products. The compd., needles, m. 260° (with decompn.), produced from *p*-acetylaminophenetidine had the compn.  $(EtOC_6H_4NHAc)_2SeSO_4 \cdot H_2O$ , while anti-pyrine yielded a *diantipyril selenide*,  $(C_{11}H_{11}ON)_2Se$ , colorless needles, m. 240° (with decompn.).

**Organic compounds containing phosphorus.** J. D. RIEDEL. Ger. 299,992, 1917. Unsatd. hydroxy fatty acids of high mol. wt. on treatment with P trihalides or oxyhalides yield as primary products acid halides in which the OH group is intact; on hydrolysis of these products with  $H_2O$ , P derivs. of the hydroxy acids are obtained which may be converted into the salts of the alk.-earth metals in the usual way. Ricinistearolic acid and ricinolic acid on treatment with  $PCl_3$  or  $PBr_3$  yield compds.  $C_{18}H_{33}O_4P$  and  $C_{18}H_{31}O_4P$ , resp.

**Derivatives of the 9,10-dichloroanthracenes.** FARBW. VORM. M. L. & B. Ger. 296,019, 1917. The 9,10-dichloroanthracenes combine directly with  $HNO_3$  in indifferent, cold media, giving well-defined, cryst. products, probably of the constitution

$$C_6H_4 \begin{array}{c} \diagup CCl(OH) \diagdown \\ \diagdown CCl(NO_2) \diagup \end{array} C_6H_4$$
 These decompose most readily, especially on warming with concd.  $H_2SO_4$ , or organic solvents or diluents, giving anthraquinones. Thus,

9,10-dichloroanthracene itself gives the additive compd., specified above, which crystallizes in very pale yellow needles, and decomposes at  $90-5^{\circ}$  into anthraquinone. 2,9,10-Trichloroanthracene yields a similar  $\text{HNO}_3$  compd., which gives 2-chloro-anthraquinone, m.  $204-6^{\circ}$ , on decompn.

**Aryl sulfites.** BADISCHE. Ger. 303,033, 1916. Aromatic sulfites are obtainable by treating aromatic OH compds. with thionyl chloride in the presence of pyridine or other suitable organic bases; the hydroxy acids do not show this behavior. *Phenyl sulfite*,  $b_{12}$   $185^{\circ}$  (in H), *o-tolyl sulfite*,  $b_{12}$   $192^{\circ}$  (corr.), *m-tolyl sulfite*,  $b_{12}$   $195-6^{\circ}$  (corr.), and *p-tolyl sulfite*,  $b_{12}$   $199^{\circ}$  (corr.), were obtained by the interaction of phenol or the cresol with thionyl chloride in the presence of pyridine and  $\text{CS}_2$ ; they are very stable towards  $\text{H}_2\text{O}$  and aq. alkalis, whereas some of their homologs, especially such as contain negative groups, readily undergo decompn. The following compds. of this type were also prepd.: *thymyl sulfite*;  $\alpha$ -*naphthylsulfite*, indistinct crystals, m.  $92-3^{\circ}$ ;  $\beta$ -*naphthyl sulfite*, nacreous powder, sensitive to  $\text{H}_2\text{O}$ ; *p-chlorophenyl sulfite*,  $b_{12}$   $213-4^{\circ}$ , solidifiable to a cryst. solid.

**Condensation products of isatin and ketones.** CHEM. FABRIK AUF AKTIEN (VORM. E. SCHERING). Ger. 301,591, 1918. Condensation products, of unexplained nature, are obtained by mixing acetophenone or its derivs. with isatin and  $\text{NH}_3$  soln. Acetophenone itself gives pale yellow products,  $\text{C}_{16}\text{H}_{12}\text{O}_3\text{N}$  (?), m.  $152-3^{\circ}$ ; *p*-tolyl Me ketone yields a white product, m.  $165-7^{\circ}$ ; deoxybenzoin forms a product, m.  $147^{\circ}$ ; and the product from 3-nitro-4-hydroxyacetophenone forms yellow crystals, m.  $191^{\circ}$ .

**Condensation products from aromatic hydroxysulfonic acids.** BADISCHE. Ger. 301,451, addition to 300,567, 1917. Phenolic mono- or di-acids are condensed with aromatic hydroxysulfonic acids, or with aromatic hydroxy compds. followed by sulfonation of the products. E. g.,  $\beta$ -naphthol-6-sulfonic acid is condensed with *p*-homosaligenin, *p*-cresol with *p*-cresol dialc. (the product m.  $215^{\circ}$ ), and 2-chloro- $\alpha$ -naphthol with *p*-homosaligenin and dihydroxyditolylmethane (m.  $126^{\circ}$ ; from HCO and *p*-cresol).

**Carbamic esters and their *N*-alkyl derivatives, and carbonic esters.** BAYER & Co. Ger. 296,889, 1917. Homologs of phenol, except the cresols, are converted into carbonates or carbamates in the usual way. The products are odorless and tasteless, and have anthelmintic properties. Thus, *p*-tert.-butylphenol reacts with  $\text{COCl}_2$  to form *p*-tert.-butylphenyl carbonate,  $\text{CO}(\text{OC}_6\text{H}_4\text{CMe}_3)_2$ , m.  $108^{\circ}$ , in the presence of pyridine, and *p*-tert.-butylphenyl *N*-dimethylcarbamate,  $\text{NMe}_2\text{CO}_2\text{C}_6\text{H}_4\text{CMe}_3$ , m.  $92^{\circ}$ , in the presence of dimethylamine, while the corresponding carbonate crystallizes in platelets or needles, m.  $123-4^{\circ}$ . *p*-Isoamylphenyl carbamate, m.  $73-4^{\circ}$ , *p*-benzylphenyl carbamate, m.  $144^{\circ}$ , *p*-isopropylphenyl carbamate, m.  $93-5^{\circ}$ , and *o*-allylphenyl carbamate, m.  $122-3^{\circ}$ .

**Derivative of hexamethylenetetramine.** LEO EGGER. Ger. 303,450, 1915. Hexamethylenetetramine acetylsalicylate, m.  $118-9^{\circ}$ , is prepd. by the gradual addition of  $(\text{CH}_2)_6\text{N}_4$  (1 mol.) to a soln. of acetylsalicylic acid (1 mol.) in a restricted vol. of ether.

**Tertiary amines.** O. MATTER. Ger. 301,450 and 301,832, 1918. Cl derivs. of the hydrocarbons are heated with sodamide, the mixt. being stirred, and, if necessary, agents like Cu gauze or Cu powder being employed as catalysts. Thus, chlorobenzene yields triphenylamine, benzyl chloride at  $110-20^{\circ}$  gives tribenzylamine, and isoamyl chloride at  $210-20^{\circ}$  forms tri-isoamylamine. Mixts. of the Cl compd. and a primary amine may also be heated with sodamide, when, if the amine contains a different radical, a mixed tert.-amine results. Thus, benzyl chloride, benzylamine, and sodamide, at

100–10°, yield tribenzylamine, benzyl chloride and aniline produce dibenzylaniline, and benzyl chloride and *p*-toluidine give dibenzyl-*p*-toluidine.

**Alkylselenocarbamides.** CHEM. FABRIK VON HEYDEN. Ger. 305,262, 1918. Alkylselenocarbamides are prepd. by the action of  $H_2Se$  on alkylcyanamides. The substances have a therapeutic value in the treatment of cancerous disease, and serve as intermediate products in the production of the more stable alkyl halide additive compds. Alkylselenocarbamide forms almost colorless needles, m. 93°, which become superficially red owing to the sepn. of Se; it unites with Br and I and reduces alk. permanganate. It is very sensitive to air and light. The Hg and Pb salts eliminate Se. Ethylselenocarbamide forms colorless needles, m. about 125°.

**Derivatives of alkylselenocarbamides.** CHEM. FABRIK VON HEYDEN. Ger. 205,263, 1918. The alkylselenocarbamides combine readily with alkyl halides to yield compds. in which the Se is more firmly combined than in the parent selenocarbamides; they are more stable towards light and more sol. in  $H_2O$ . Their compn. is probably expressed by the formula  $Alk.NH.C(NH_2):SeI.Alk$ . The compd. formed from allylselenocarbamide and EtI forms white leaflets, m. about 100°; the I is pptd. as AgI by  $AgNO_3$ . The Se is not pptd. as Pb or Hg selenide by Pb or Hg salts, as in the case of allylselenocarbamide. The compd. from ethylselenocarbamide and allyl bromide, m. 115°.

**Hydrogenated compounds.** BAYER & Co. Ger. 305,347, 1918. The process depends on the action of alkali or alk.-earth metals and alcs. on isocyclic or heterocyclic bases in the presence of an inert solvent; the alc. is preferably added at the same rate as it is used in the reaction. Thus tetrahydro- $\alpha$ -naphthylamine is formed when a soln. of  $\alpha$ -naphthylamine in alc. is added to a mixt. of solvent naphtha and Na at a temp. above 130°; with a solvent of lower b. p., such as toluene, dihydro- $\alpha$ -naphthylamine is obtained. 2-Methylquinoline when hydrogenated at above 130°, yields tetrahydro-2-methylquinoline, which gives a characteristic blood-red coloration with  $FeCl_3$  and  $K_3Fe(CN)_6$ . The picrate, m. 153–4°.

**Trialkylethanolarsonium hydroxides and their salts.** CHEM. WERKE GRENZACH. Ger. 303,032, 1916. By hydrolysis of haloethyltrialkylarsonium halides with  $H_2O$  at higher temps., it is possible to produce arsonium compds, analogous to choline, and having valuable therapeutic properties. Trimethylarsine and ethylene bromide react at 100–5°, yielding *trimethyl- $\beta$ -bromoethylarsonium bromide*, prismatic tablets, m. 239° (corresponding *picrate*, m. 189°), which is converted by  $H_2O$  at 180° into *trimethyl- $\alpha$ -ethanolarsonium bromide*,  $C_4H_9OBrAs$ , deliquescent prisms, m. 219°. *Triethyl- $\beta$ -bromoethylarsonium bromide*, m. 225°, obtained from  $AsEt_3$  and  $C_2H_4Br_2$ , on treatment with  $H_2O$  at 180°, yields *triethylethanolarsonium bromide*, needles.

**Guaiacol.** E. H. ZOLLINGER and H. RÖHLING. Ger. 305,281, 1918. A weak base such as  $Na_2CO_3$  or  $NaHCO_3$  is gradually added to a mixt. of catechol with the alkali or alk.-earth salts of methylsulfuric acid in the presence of veratrole as diluent at 160–80°; the yield is more than 85% of that theoretically possible.

**Homologs of emetine.** FARBW. VORM. M. L. & B. Ger. 301,498, 1918. Cephaeline is converted into its Et, propyl, and benzyl ethers.

**Paraffins.** BAYER & Co. Ger. 296,741, 1917. Alcs. are converted into their formates, and these are heated. Thus, dihydrocholesteryl formate, narrow tablets, m. 84°, when heated at 290° under 100 mm. pressure, yields cholestane, and myricyl alc. gives triacontane. The products are purified by mixing the ethereal soln. with  $AcOAc$  and concd.  $H_2SO_4$ , and evapg. the ether, when the pure hydrocarbons sep.

## II. BIOLOGICAL CHEMISTRY.

HATTIE L. HEFT AND WILLIAM J. GIES.

### A. GENERAL.

FRANK P. UNDERHILL.

**Connection of diastase, peroxidase and catalase.** H. MAGGI. Univ. Berne. *Helvetica chim. acta* 1, 433-51 (1918).—HCHO can function as a catalase, a peroxidase, and a diastase. The diastatic activity was shown by a study of the behavior of starch plus HCHO using the capillarization method, and by other expts. The aldehyde group may combine with  $H_2O_2$  to form a peroxide  $-CH(OH)(O-OH)$  which may react (a) with an excess of  $H_2O_2$  to liberate mol. O (catalase action), or (b) with a chromogen to form a pigment (peroxidase action). The aldehyde group may combine with water to form an unstable glycol  $-CH(OH)_2$ ; this decomposes with the liberation of H and OH which attack the starch substrate and hydrolyze it (diastase action) before they reunite to form water. Diastase may be considered as a complex radical  $R_F$  combined with an aldehyde (CHO) group. Study was also made of the development of a blue color in soln. containing I and starch-cleavage products and possessing a red color. It was concluded that unchanged starch must be present as well as a substance capable of liberating I. JOSEPH S. HERBURN.

**Amphoteric colloids. I. Chemical influence of the hydrogen-ion concentration.** J. LOEB. *J. Gen. Physiol.* 1, 39-60 (1918); cf. following abstract.—Gelatin which has been treated with NaOH and then washed free from excess alkali is influenced only by the cation of an added salt, e. g.,  $M/128 Na_2SO_4$  has the same effect in causing increased osmotic pressure, viscosity, alc. pptn. and swelling as  $M/64 NaCl$  has, or any neutral salt with monovalent cation, while salts with bivalent cations cause no such increase and if added in small quantity to a salt of a univalent cation may inhibit the effect of the univalent cation. Gelatin treated with HCl and then freed from excess by washing reacts only with the anion of neutral salts,  $M/128 Ca(NO_3)_2$  having the same effect as  $M/64 NaNO_3$ , and the Ca has no depressing effect, showing that the gelatin does not react with the cation. Bivalent anions inhibit the effect of monovalent anions. By making use of the depressing effects of bivalent ions and the opposite effect of univalent ions it can be detd. at which  $p_H$  the gelatin begins to combine with the cation and ceases to combine with the anion. This critical point lies at  $C_H = 2 \cdot 10^{-8}$  or  $p_H = 4.7$  which is the isoelectric point for gelatin, and gelatin when it ionizes can only exist as an ion on the less acid side of the isoelectric point ( $p_H = 4.7$ ), as a cation only on the more acid side of its isoelectric point. When gelatin has been transformed into sodium gelatinate by treating it for some time with  $M/32 NaOH$  and is then subsequently treated with HCl it shows, on the more acid side of the isoelectric point, effects of the acid treatment only, while the effects of the alkali treatment disappear completely, showing that the negative gelatin ions formed by the previous treatment with alkali can no longer exist in a soln. with a  $p_H = 4.7$ . When gelatin is first treated with acid and afterward with alkali on the alkaline side of the isoelectric point only the effects of the alkali treatment are noticeable. On the acid side of the isoelectric point amphoteric electrolytes can only combine with the anions of neutral salts, on the less acid side of their isoelectric point only with cations, and at the isoelectric point neither with the anion nor cation of a neutral salt. The alleged effect of the Hofmeister series of anions on the swelling and osmotic pressure of common gelatin in neutral soln. would mean, if true, that the anions of the neutral salts act on gelatin on the alkaline side of the isoelectric point. These statements are contrary to fact and are based on erroneous methods of work, and are also according to the present paper theoretically impossible. Cond. measurements confirm the conclusion

that gelatin cannot exist in ionized condition at the isoelectric point. Curves for osmotic pressure, viscosity, swelling and alcohol number run parallel to the cond. curve when the gelatin has been treated with acid, supporting the view that these physical properties are a function of the degree of ionization of the gelatin, although certain constitutional factors may alter the physical properties of the gelatin. The isoelectric point of an amphoteric electrolyte is a turning point for the physical properties and for the mode of chemical reactions of the ampholyte. This chemical influence of the isoelectric point upon life phenomena may overshadow its physical influence. The theory of amphoteric colloids is in its general features identical with the theory of inorganic hydroxides as  $\text{Al}(\text{OH})_3$ , whose behavior is adequately understood on the basis of the laws of general chemistry.

H. I. MATTILL.

**Amphoteric colloids. II. Volumetric analysis of ion-protein compounds; the significance of the isoelectric point for the purification of amphoteric colloids.** JACQUES LOEB. Rockefeller Inst. *J. Gen. Physiol.* 1, 237-54(1918); cf. preceding abstract.—At its isoelectric point,  $p_H$  4.7, gelatin combines with neither anion nor cation; on the alk. side of this point it combines only with cations, on the more acid side only with anions; therefore gelatin exists only as an anion on the alk. side, and only as a cation on the more acid side of the isoelectric point, and as neither an anion nor a cation at that point. The simplest method of obtaining amphoteric colloids approx. free from ionogenic impurities probably consists in bringing them to the H-ion concn. characteristic of their isoelectric point. When gelatin is combined with a monovalent ion (Ag, Br, CNS) the curve, which represents the amt. of ion-gelatin formed, runs approx. parallel to those for swelling, osmotic pressure, and viscosity. "The influence of ions on these properties is detd. by the chem. or stoichiometrical and not by the 'colloidal' condition of gelatin." These curves and the soly. of pure gelatin in  $\text{H}_2\text{O}$  drop sharply at the isoelectric point, and a ppt. forms; the decrease in soly. may be due to lack of ionization or to formation of an automeric or polymeric compd. of gelatin. "On account of this sudden drop slight changes in the H-ion concn. have a considerably greater chem. and physical effect in the neighborhood of the isoelectric point than at some distance from this point. This fact may be of biological significance since a number of amphoteric colloids in the body seem to have their isoelectric point inside the range of the normal variation of the H-ion concn. of blood, lymph, or cell sap. Our expts. show that while a slight change in the H-ion concn. increases the water soly. of gelatin near the isoelectric point, no increase in the soly. can be produced by treating gelatin at the isoelectric point with any other kind of monovalent or polyvalent ion, a fact apparently not in harmony with the adsorption theory of colloids, but in harmony with a chem. conception of proteins."

JOSEPH S. HEPBURN.

**Effect of "ground glass" on the gastro-intestinal tract of dogs.** JAMES S. SIMMONS AND WM. C. VON GLAHN. U. S. Army. *J. Am. Med. Assoc.* 71, 2127-8(1918).—Of 120 samples of food received at the Southern Dept. Lab., Fort Sam Houston, Texas, glass was found in 8. In a majority of these it could have been accidental and in a few it had evidently been added by those sending specimens. In an attempt to det. what lesions, if any, are produced by glass in the gastrointestinal tract, feeding expts. were carried out on 10 dogs. Daily records were made of the general appearance, wt., temp., blood count, and feces examn. (gross and microscopic) for blood, pus, epithelium, etc. At the completion of the expts. the dogs were chloroformed and examd. post-mortem. Broken chem. glassware was ground in a stone mortar and the product divided into 5 sizes by sieves. The dogs were divided into two series of five dogs each and given doses of 1 and 5 g. of each size, resp., the glass being mixed with lean meat. All grades of glass except the finest were easily detected by the naked eye. The first two doses were given at intervals of four days; then daily until the dogs were

chloroformed. Post-mortem examn. failed to find any lesion gross or microscopic, and with the exception of the presence of glass the appearances were precisely the same as those in control dogs. L. W. RIGGS.

**The formation of enzymes. VII. MARTIN JACOBY.** *Biochem. Z.* 88, 35-42 (1918); *J. Chem. Soc.* 114, I, 469; cf. *C. A.* 11, 2207, 2683, 3286; 12, 816, 1300, 2327.—The conditions for the formation of the catalase of *Proteus* were investigated. While leucine is essential for the formation of urease by this species of bacteria, this is not the case for the formation of the catalase. Other amino acids, such as aspartic acid and alanine, can be employed and a considerable development of this enzyme takes place in a medium containing, besides the essential inorg. salts and one of these amino acids, Na lactate. The catalase acts after the bacteria have been killed (that is, in the presence of toluene). If inactivated by not too large quantities of  $\text{HgCl}_2$  and too long a period of contact with this substance, its activity can be restored by treatment with KCN. C. J. WEST.

**The catalase of bacteria. MARTIN JACOBY.** *Biochem. Z.* 89, 350-4 (1918); *J. Chem. Soc.* 114, I, 517.—J. describes attempts to prepare a pure catalase. *Bacillus proteus* was grown on the medium already employed by the author, which contains, besides the inorg. salts, Na aspartate and lactate. From such cultures, an active catalase could be obtained by pptn. with  $(\text{NH}_4)_2\text{SO}_4$ ,  $\text{MgSO}_4$ , and NaCl. The ppt. obtained was dissolved in  $\text{H}_2\text{O}$ . A catalase could also be pptd. by  $\text{HgCl}_2$ ; in this case, an active prepn. was obtained by redissolving the ppt. in KCN soln. C. J. WEST.

**The photolytic and photodynamic action of an  $\alpha$ -furo- $\beta$ -diazole.** P. R. KOGLER. *Biochem. Z.* 89, 204-10 (1918); *J. Chem. Soc.* 114, I, 515.—The substance employed was  $\beta$ -naphthoxadiazole-4-sulfonic acid, which undergoes change on exposure to light. The photodynamic effects were demonstrated on the protozoön *Colpidium colpoda*. C. J. WEST.

**Arrest of alcoholic fermentation in the aldehyde stage. An experimental confirmation of the acetaldehyde pyruvic acid theory.** CARL NEUBERG AND ELSA REINFURTH. *Biochem. Z.* 89, 365-414 (1918); *J. Chem. Soc.* 114, I, 517-8.—N. has shown that yeast contains an enzyme which decomposes pyruvic acid into AcH and  $\text{CO}_2$ ; furthermore AcH is readily reduced during yeast fermentation to EtOH. It seemed, therefore, probable that AcH is an intermediate product in alc. fermentation. N. and R. now show that considerable amts. of AcH can be obtained in the ordinary yeast fermentation of sugars and can be isolated if the fermentation is carried out in the presence of  $\text{Na}_2\text{SO}_3$ . The equations representing the reactions are given. As 0.5 of the mol. should yield AcH, which acts as acceptor for the H evolved, it should not be expected that 1 mol. of sugar should yield more than 1 mol. of  $\text{CO}_2$  and one mol. of aldehyde. An amt. of aldehyde equiv. to 73.45% obtainable on this theory has been obtained. Details are given of the methods employed for the quant. determination of the aldehyde and alcohol formed during fermentation. C. J. WEST.

**Methylation of proteins. J. HERZIG AND KARL LANDSTEINER.** *Monatsh.* 39, 369-84 (1918); *J. Chem. Soc.* 114, I, 508-9.—In the earlier investigations, it was shown that for various proteins the action of  $\text{CH}_3\text{N}_3$  gives products containing a fairly uniform % of Me radical, as indicated by the figures 3.68-4.86% of MeO and 3.72-5.34% of Me attached to N; silk fibroin alone was exceptional, the product from this containing 2.79% MeO and 4.93% of imino-Me, even after repeated methylation. Wool, after being submitted repeatedly to the action of  $\text{CH}_3\text{N}_3$ , contains 5.89% of MeO and 6.28% of amino-Me. In a similar examn. of the alc.-sol. protein from grain, it was found that the zein of maize is rather resistant to  $\text{CH}_3\text{N}_3$ , giving after several treatments a product containing 4.17% of MeO and only 2.9% of amino-Me; gliadin from wheat is

more reactive, and gives a product containing 7.06% of MeO and 2.56% of imino-Me. Non-coagulated serum albumin from the horse gives results similar to those obtained with the coagulated product. (With F. ZIPPERER and M. QUITTNER.) A similar examn. was made of the effect on proteins of a 10-hr. treatment with a boiling 1% soln. of HCl in MeOH; the products gave the following analytical results: Silk fibroin, 1.4% MeO, iminomethyl almost identical with that of the original substance. Wool, 3.80% MeO, 1.49% iminomethyl. With zein, and particularly with gliadin, the HCl causes considerable hydrolysis, a similar result being also obtained with Witte's peptone. The product from zein contains 5.47-6.18% of MeO but the Me-N content is almost unaltered. With gliadin, a large proportion passes into soln., the undissolved residue as well as the portion of the dissolved material precipitable with  $\text{Et}_2\text{O}$ , containing approx. 7% of MeO; it is probable that the extent of the hydrolytic effect of the MeOH-HCl is greater than these figures indicate, because the resulting glutamic acid is remarkably resistant to esterification by this reagent. It is also probable that to some extent esterification products formed in the earlier stages of the treatment undergo subsequent hydrolysis by the action of  $\text{H}_2\text{O}$  resulting from the interaction of the HCl and MeOH. The product of the reaction between zein and gliadin and MeOH-HCl on treatment with  $\text{CH}_3\text{N}_3$ , undergoes a marked increase in the MeO content, which, however, is probably due to the presence of phenolic groups.

C. J. WEST.

**Biology of silicic acid and aluminium oxide in birds feathers.** MAX GONNERMANN. *Z. physiol. Chem.* 102, 78-84(1918); *J. Chem. Soc.* 114, I, 465.—Feathers almost always contain silicic acid and  $\text{Al}_2\text{O}_3$ . The amts. vary considerably in different birds and appear to depend largely on the content of these substances in the food. The largest quantity of silicic acid found was in the feather of the dove, *Columba palumbus* (77% of the total ash), while the feathers of the jay, *Corvus glandarius*, contained the most  $\text{Al}_2\text{O}_3$  (2.46%). Apparently, the feathers constitute a storing place for both substances.

C. J. WEST.

**Chemical studies on physiology. V. "Soluble" and "insoluble" colloids, genuine and spurious jellies, protoplasm and cell permeability.** E. HERZFELD AND R. KLINGER. *Biochem. Z.* 88, 232-82(1918); *J. Chem. Soc.* 114, II, 355; cf. *C. A.* 12, 809, 2094, 2373.—This is a theoretical paper in which H. and K. distinguish between "soluble and insoluble" colloids. They assume that in all cases of soln. the solute forms combinations with many mols. of the solvent, and solns. of all stages between molecularly dispersed and colloiddally dispersed particles exist. The latter form "soluble" colloids. In contradistinction to these, "insoluble" colloids exist, which owe their dispersion to the adsorption of the substances on their surface with great affinity for water. To the latter class proteins belong. These views have been expressed in previous papers. Gelatin is regarded as a mixt. of polypeptides polymerized by means of Ca salts. Jellies are formed from colloids with colloids with great power of combining with water, and come into existence when the whole of the water in the system is accumulated on the surface of the colloidal particles. Corresponding with the "soluble" and "insoluble" colloids are the "genuine" and "spurious" jellies, the former of which only are reversible. H. and K. discuss the applications of their ideas to the problems of cell permeability and metabolism.

C. J. WEST.

**Coenzyme of fermentation in the animal body. II.** OTTO MEYERHOF. *Z. physiol. Chem.* 102, 1-32(1918); *J. Chem. Soc.* 114, I, 464; cf. *C. A.* 12, 2092.—The coenzyme of zymase appears to exist in almost all the tissues of the frog and rabbit. It is present in relatively the largest amt. in the frog muscle; it is absent from blood serum. It is most readily extd. by boiling water. Cold water exts. contain the coenzyme, but an inhibitory substance is also present which is destroyed on boiling. The inhibitory substance exerts its action on zymase and not on the coenzyme and

appears to be of a protein nature. The chem. properties of the coenzyme in muscle resemble those associated with the coenzyme in yeast. It is dialyzable, not destroyed by boiling, pptd. by alc., adsorbed by charcoal, etc. The course of fermentation with the muscle coenzyme is analogous to that observed when the coenzyme from yeast is employed. The respiratory substance which accelerates the oxidation process in muscle appears to be identical with the coenzyme of yeast and muscle. A similar coenzyme is also present in germinating yeast.

C. J. WEST.

**Action of chymosin and pepsin.** IV. Action of the enzymes on sodium caseinogenate. OLOF HAMMARSTEN. *Z. physiol. Chem.* 102, 33-77(1918); *J. Chem. Soc.* 114, I, 459-60; cf. *C. A.* 9, 2904.—Two exts. of gastric mucous membrane may show equal enzymic activity when tested by their power of coagulating milk, and yet show considerable differences in their digesting power on fibrin or white of egg. This want of parallelism is found also when the substrate chosen in each case is caseinogen and the activity is tested first in the presence of alkali and then in that of acid. In the former case the solns. become opalescent and a ppt. forms, while albumoses are produced in considerable amt. and although there does not appear to be a direct proportionality between the strength of the chymosin and the time in which the opalescence becomes of a definite degree or the ppt. just perceptible, or between the quantity of chymosin present and the amt. of albumose produced in a given time, yet the relative strengths of two chymosin solns. may be compared in either of these ways. The results can be interpreted most easily by regarding chymosin and pepsin as sep. enzymes, and this view is confirmed by the fact that the differences observed between the coagulating and digesting powers of the 2 exts. are exactly paralleled by the differences in their behavior towards caseinogen in alk. and acid soln., resp. Thus, if one of two solns. of equal peptic power clots milk with greater rapidity than the other, then its action on caseinogen in alk. soln. is found to be much more marked and rapid than is the case with the other enzymic soln. V. Action of the enzymes on legumin from peas. *Z. physiol. Chem.* 102, 105-47; *J. Chem. Soc.* 114, I, 510.—Chymosin acts on other proteins besides caseinogen, forming albuminoses. Acid- and alkali-legumin are hydrolyzed by chymosin in neutral solns. or in the presence of so little acid that any pepsin present would exert little or no hydrolytic action. The results are considered by the author to support the theory that assigns a sep. identity to chymosin and pepsin.

C. J. WEST.

Cleavage of digitonin cholesteride (WINDAUS) 10.

CONKLIN, EDWIN G.: *Heredity and Environment*. Revized 2nd Ed. Princeton: Princeton University Press. 550 pp. \$2.00. For review see *J. Phys. Chem.* 22, 647.

## B. METHODS AND APPARATUS.

STANLEY R. BENEDICT.

**Detection of bile pigments.** DEJAGER. *Pharm. Zentr.* 58, 442(1917); *Schweiz. Apoth.-Ztg.* 56, 264(1918).—To test urine for bile pigment: Add 2 drops of 0.5%  $\text{NaNO}_2$  soln. to a 5 cc. sample and overlay with dil. HCl; a green ring in the latter indicates the presence of bile pigments. Another test is carried out as follows: To the sample add several drops of  $\text{ZnCl}_2$  soln. and filter off the ppt.; overlay the filtrate with a mixt. of 1 cc. concd. HCl, 9 cc. alc., and 2 drops of 0.5%  $\text{NaNO}_2$  soln. If bile pigment is present the filtrate shows an emerald-green color.

C. O. EWING.

**Detection of blood in urine.** FULD. *Pharm. Zentr.* 58, 467(1917); *Schweiz. Apoth.-Ztg.* 56, 265(1918).—The reagent is prepd. by dissolving 0.2 g. rhodamine in 50 cc. alc. and decolorizing the resulting strongly fluorescent light red soln. by boiling it with 5 g. Zn dust and 4 cc. 10% NaOH soln. A 1:10,000,000 soln. of dried blood produces a red color in the reagent.

C. O. EWING.

The determination of sugars in so-called "levulosuria." J. PRESCHER. *Pharm. Zentr.* 59, 43-4(1918); *Chem. Zentr.* 1918, I, 881.—The following method is more advantageous than the Soxhlet method for the detn. of levulose and dextrose in urine when the disparity between their amts. is not too great. A measured portion of urine is cleared with Pb acetate, made up to volume, and a portion polarized at 15°; in another portion the total sugars are detd. as invert sugar by the method of Meiszl. Since in about 10% soln.  $[\alpha]_D^{15}$  for dextrose is 52.5 and for levulose 95.5,  $[\alpha] = -0.955 l + 0.525 d$ , whence, since

$$d = s - l \text{ and } l = s - d, l = \frac{(0.525 s - [\alpha])}{1.48} \text{ and } d = \frac{(0.955 s + [\alpha])}{1.48},$$

where  $d$  = dextrose,  $l$  = levulose,  $s$  = total sugars, and  $[\alpha]$  = sp. rotation at 15° in a 100 mm. tube. If the reading is made at 20° the no. 1.48 should be replaced by 1.45.

C. O. EWING.

Modification of the technic of the Voges and Proskauer reaction. GEO. C. BUNKER, EDWARD J. TUCKER AND HOWARD W. GREEN. *J. Bact.* 3, 493-8(1918).—The use of 0.5 cc. of a 45% soln. of NaOH, Syracuse watch glasses, and 1 cc. of the culture results in the development of a greater number of positive Voges and Proskauer reactions in a shorter interval of time than the method given in the latest (1917) edition of "Standard Methods of Water Analysis." An incubation period of two days at 30° is recommended in place of that of 5 days in order to obtain the max. number of positive Voges and Proskauer reactions from glucose- $K_2HPO_4$  broth.

JOHN T. MYERS.

Determination of protein sugar. H. BERRY AND L. RANDOIN-FANDARD. *Compt. rend. soc. biol.* 81, 476-80(1918).—The blood or plasma must be dild. with at least 3 vols.  $H_2O$  for the former and 1½ vols.  $H_2O$  for the latter before hydrolysis of the protein-sugar compd. The same results were obtained by hydrolyzing this compd. with various acids ( $HCl$ ,  $H_2SO_4$ ,  $HF$ ), providing the proportion of acid and period of heating were properly varied. The following method is proposed for detn. of combined or protein sugar in the blood: Collect the blood in an equal vol. of 2:1000 NaF soln. (e. g., 50 cc. of each), add 90 cc. distd.  $H_2O$  and (drop by drop) 4 cc. of concd.  $H_2SO_4$  (free from  $HNO_3$  and  $HNO_2$ ) dild. with 10 cc.  $H_2O$  and heat 40 mins. in an autoclave at 120°. After cooling neutralize with dil. NaOH, add slowly with const. agitation 80 cc. of 40%  $Hg(NO_3)_2$  soln. (prepd. by dissolving  $Hg(NO_3)_2$  in  $H_2O$  containing  $HNO_3$ ), add NaOH to very slight alk. to litmus and then add 1-2 drops 50% AcOH to produce slight acidity. Complete the vol. to 400 cc., filter and remove excess Hg with  $H_2S$  or Zn powder. If it is necessary to concentrate the soln. owing to very low concn. of reducing sugar this should be done at a temp. below 50° *in vacuo*. For detn. of combined sugar in the plasma collect the blood in a vessel to which 0.10 g. finely powdered NaF has been added for each 50 cc. of blood, stir gently, centrifuge at once and separate the plasma by decantation. The operation requires 6-7 mins. and no coagulation or glycolysis occurs under these conditions. Fifty cc. of the plasma are then dild. with 75 cc.  $H_2O$ , mixed with 2.5 cc. concd.  $H_2SO_4$  and heated at 120° for 30 mins. The rest of the procedure is the same as for blood except that 35 cc. of  $Hg(NO_3)_2$  soln. are sufficient. Detn. of reducing sugar is effected in both cases by the Bertrand method and protein or combined sugar is calcd. by difference between total sugar as detd. above and free sugar. Results obtained with the blood of various animals at varying dilns. with  $H_2O$  and after hydrolysis with varying proportions of  $HCl$  and  $H_2SO_4$  are given in tabulated form.

H. S. PAINE.

Simple method of detecting methylene blue in urine; spectroscopic examination of biological liquids in layers of considerable depth. CL. GAUTIER. *Compt. rend. soc. biol.* 81, 496-7(1918).—Methylene blue may be readily detected by spectroscopic examn. after adding 1 drop of an aq. soln. containing 0.5 g. per l. to 200 cc. of filtered

urine; an observation of approx. 30 cm. length should be used. The above concn. of methylene blue does not represent the limit of sensitiveness of the method. Methylene blue exhibits a very intense absorption band in the red and a 2nd absorption band in the orange-yellow. Thionine may be detected by an intense absorption band in the yellow-orange-red with penumbra near the green. Fuchsin has a large (not very dark) absorption band in the green and eosin has a characteristic absorption band near the green and in the green-blue. H. S. PAINÉ.

**Estimations of the tension of carbon dioxide in the alveolar air by the Henderson-Russell modification of Haldane's method and their application for testing the stimulability of the breathing center.** EUGEN JENNI. *Biochem. Z.* 87, 331-58(1918); *J. Chem. Soc.* 114, I, 462.—By means of the modification by Henderson and Russell of Haldane's method, it was found that the  $\text{CO}_2$  tension of the alveolar air remained const. over prolonged periods. When the subject of expt. is used to the procedure, the variations amt. to but 2-3 mm. of Hg; the method is not, however, well adapted to clinical purposes. In case of emphysema investigated, the tension of  $\text{CO}_2$  was high. The method can be employed for testing the irritability of the breathing center. For inhibition, the drugs morphine and pantopone were employed; both cause marked increase in the tension of  $\text{CO}_2$  in the alveolar air. The preparation of Pavon-Ciba, in corresponding therapeutic doses, causes little alteration in this tension and its inhibitory action on the breathing center is less than that of morphine or pantopone. Ak. is an excitant of the inhibitory center in these doses used by J. C. J. WEST.

**Detection of *d*-glycuronic acid and other acids with similar behavior by the naphtha-resorcinol reaction.** A. W. VAN DER HAAR. *Biochem. Z.* 88, 205-12(1918); *J. Chem. Soc.* 114, II, 376.—An application of Neuberg and Saneyoshi's modification of Tollen's reaction, as applied to plant products. The substance is 1st hydrolyzed with 5%  $\text{H}_2\text{SO}_4$ , the mixt. is then neutralized with  $\text{Ba}(\text{OH})_2$ , and concd. after filtration,  $\text{Pb}(\text{OAc})_2$  is added, and after filtration, basic lead acetate; the glucuronate is contained in the ppt. thus produced, and this is then heated with 10 cc. of 10%  $\text{HCl}$  and 100 mg. of naphtha-resorcinol for 1 min. After cooling to  $50^\circ$ ,  $\text{C}_6\text{H}_6$  is added, and if glucuronic acid is present, this on shaking takes up a violet pigment, which gives a characteristic D band of the spectrum. C. J. WEST.

**Combined estimation of tyrosine and uric acid in the same solution.** E. HERZFELD AND R. KLINGER. *Biochem. Z.* 88, 283-5(1918); *J. Chem. Soc.* 114, II, 415.—Folin's phenol reagent is employed. It gives a color twice as strong with tyrosine as with uric acid. The color with the soln. of the 2 substances is 1st estd., then uric acid is destroyed by  $\text{H}_2\text{O}_2$  and  $\text{NaOH}$ , then the phenol reagent is added again, under conditions specified and the tyrosine alone is detd. colorimetrically. C. J. WEST.

**The Haldane-Henderson method for estimating the tension of alveolar carbon dioxide and the influence of oxygen on the stimulability of the respiratory centers.** MOTIO YAMADA. *Biochem. Z.* 89, 27-47(1918); *J. Chem. Soc.* 114, I, 511.—A new valve is described for use with Henderson's modification of Haldane's method for estg. alveolar  $\text{CO}_2$ . It was found that when the amt. of  $\text{CO}_2$  inhaled was greater than normal, the alveolar ventilation was better when the gas was mixed with pure O than when mixed with air. Hence O has a favorable influence on the breathing center. No influence could be found to be exerted on the respiratory center by the inhalation of pure O. C. J. WEST.

**Detection of mercury in urine, with employment of a new solvent for mercuric sulfide.** S. GUTMAN. *Biochem. Z.* 89, 199-203(1918); *J. Chem. Soc.* 114, II, 409.—The solvent is a soln. of  $\text{HI}$ , prepd. by dissolving 5 g.  $\text{KI}$  in 12 cc. 10%  $\text{H}_2\text{SO}_4$  and dilg. to 25 cc. The urine is treated 1st with  $\text{HCl}$  and  $\text{KClO}_3$  to destroy the

org. matter. From the slightly acid soln. Hg is pptd. by  $H_2S$ . The sulfide is purified by dissolving in aqua regia and repptn. with  $H_2S$ . This ppt., if it is  $HgS$ , should be insol. in hot  $HNO_3$  but sol. in aqua regia and the given soln. of HI. C. J. WEST.

**Standardization of antimeningococcic serum.** HAROLD L. AMOSS AND PENELOPE MARSH. Rockefeller Inst. *J. Exp. Med.* 28, 779-90(1918).—The results obtained were variable. A. and M. feel that the protective power for laboratory animals is an unsuitable index of its value in human medicine and is inferior to the agglutination titer as a standard of potency. C. J. WEST.

**Clinical value of freezing-point determinations.** FRITZ EIGENBERGER. *Z. physiol. Chem.* 102, 166-75(1918); *J. Chem. Soc.* 114, I, 512.—The addition of urea, dextrose or NaCl to a colloidal soln. of gelatin, starch or blood-serum produces scarcely any lowering of the freezing point, measured by Beckmann's method. When an acid or alkali is added, a considerable depression may be observed but it does not equal the calcd. value. E. draws the conclusion that the detn. of the freezing point of a pathological serum is not likely to furnish any valuable clinical information. C. J. WEST.

**The microchemical estimation of nitrogen.** IVAR BANG. *Biochem. Z.* 88, 416-9(1918); *J. Chem. Soc.* 114, II, 369.—A reply to criticisms of Sjollem and Hesseschly (*C. A.* 12, 1473). C. J. WEST.

**Normal salt solution (GERSHENFELD) 17.** New reaction for acetylcarbinol (BAUDISCH) 7. Quantitative determination of gold, especially in animal tissue (CADDWELL, LEAVELL) 7. Determination of nitrite and nitrate in presence of one another (OELSNER) 7. Determination of reducing sugars (CLARK) 7. Determination of aldehyde sugars (COLIN, LIEVIN) 7.

### C. BACTERIOLOGY.

**Synthetic medium for the direct enumeration of organisms of the colonaerogenes group.** S. HENRY AYERS AND PHILIP RUPP. *J. Bact.* 3, 433-6(1918).—A simple synthetic medium has been devised in which there is a single source of N, namely,  $Na(NH_4)PO_4$  and a single source of C, namely lactose. Compn. of the medium, Soln. I:  $Na_2HPO_4$  0.4%,  $KH_2PO_4$  0.2%, lactose 1.0%; dissolve in distd. water. Soln. II: filtered soln. of agar in distd. water, 3.0%. Mix soln. I and II in equal proportions while hot and put up in definite amts. of 100 cc., or more, in flasks or bottles and sterilize. At the time of plating, after the agar medium is melted and while at its highest temp. add for each 100 cc. of medium 0.5 cc. of a 1% alc. basic fuchsin soln. and follow at once with 0.5 cc. of a freshly prepd. 5%  $Na_2SO_4$  soln. JOHN T. MYERS.

**Endo medium for the isolation of *Bacillus dysenteriae* and a double sugar medium for the differentiation of *B. dysenteriae*, *shiga* and *flexner*.** I. J. KLIGLER AND J. DEFANDORFER. *J. Bact.* 3, 437-40(1918). JOHN T. MYERS.

**Influence of dicyanodiamide on the growth of various microorganisms.** LUISE MOLLER. *Biochem. Z.* 88, 85-96(1918); *J. Chem. Soc.* 114, I, 469.—Expts. were carried out with various wild yeasts, molds and bacteria, and these indicate that dicyanodiamide has no advantage as a sole source of N for organisms. On the contrary, it exerts a deleterious action on their growth. C. J. WEST.

**General relationship of aldehydes to alcoholic fermentation.** The coenzyme of yeast. CARL NEUBERG. *Biochem. Z.* 88, 145-204(1918); *J. Chem. Soc.* 114, I, 469-70.—N. gives detailed expts. which confirm his previous statement that aldehydes generally accelerate the alc. fermentation by yeasts of dextrose and mannose. His expts. include a series of fatty aldehydes from formaldehyde up to decaldehyde, chloral hydrate, hydroxaldehydes (aldol, acetopropionaldol), unsatd. aldehydes, citronellal and citral), aromatic aldehydes (benzaldehyde, *p*-isopropylbenzaldehyde, phenylacet-

aldehyde), aromatic hydroxyaldehydes and their ethers (salicylaldehyde, *p*-hydroxybenzaldehyde, anisaldehyde, piperonal, and vanillin, which is the only aldehyde which failed to give acceleration), the unsatd. aromatic aldehyde, cinnamaldehyde, cyclic aldehydes (furfuraldehyde and cyclocitral), dialdehydes (glyoxal, isophthalaldehydes, terephthalaldehyde), ketoaldehydes (methylglyoxal and phenylglyoxal) and aldehyde acids. N. also confirms his former statement that a mixture of keto-acids with  $K_2HPO_4$  acts as a co-enzyme. He suggests that certain differences in results on this point obtained by Harden may be due to the fact that the yeast preps. employed by the latter were not quite free from co-enzymes.

C. J. WEST.

## D. BOTANY.

CARL L. ALSBERG.

A simple method of demonstrating the production of aldehyde by chlorophyll and by aniline dyes in the presence of sunlight. W. J. V. OSTERHOUT. *Am. J. Botany* 5, 511-3 (1918).—The method consists in extg. chlorophyll from fresh leaves by means of alc., shaking the alc. with  $CCl_4$ , and sprinkling the latter on filter paper in sufficient amts. to give it a deep green color. This is placed in air-tight bell jars with a large Petri dish containing 5 cc.  $H_2O$ , some being kept in the dark and others in the light until the chlorophyll is bleached to a pale green, which may require several days. The  $H_2O$  in the dishes kept in the dark gives negative tests for aldehyde; that in the dishes kept in the light gives positive tests. Aniline dyes substituted for chlorophyll also gave positive results for aldehydes.

J. J. SKINNER.

Root absorption from solutions at minimum concentrations. R. B. HARVEY AND R. H. TRUE. *Am. J. Botany* 5, 516-21 (1918).—The equil. concn. of electrolytes established by the squash, peanut, soy bean, and sweet corn grown in  $H_2O$  cultures was found to be specific for each plant. At the point of equil. between the plant and the soln., the electrolyte content of the soln. is detd. 1st by certain factors which are const. for different plants under the same conditions, such as the  $CO_2$  equil. with the air, and 2nd by the rate of cleavage of ion-producing compds. of the cell and the absorption of the ions produced. The equil. concn. value is independent of the kind of nutrient salt used, the concn. of the electrolyte, or the vol. of the soln., provided the concn. is below the toxic limit for the plant, and that the quantity of salt is within the requirements of the plant.

J. J. SKINNER.

Legumin in peas. OLOF HAMMARSTEN. *Z. physiol. Chem.* 102, 85-104 (1918); *J. Chem. Soc.* 114, I, 509-10.—The legumin prepd. from peas by extn. with salt soln. and subsequent removal of the salt by dialysis is sol. in dil. salt solns. and thus differs from the insol. legumin obtained from the peas by extn. with  $H_2O$  or dil. alkali, followed by pptn. with dil.  $AcOH$ . H. proposes to designate the former as *a*-legumin and the latter as *b*-legumin. *b*-legumin appears to be an acid metaprotein. *a*-legumin also forms a compd. with acid, which, however, is not *b*-legumin, because the latter swells in water, giving a viscid, non-filterable soln., whereas the acid compd. of *a*-legumin does not swell in water but gives a limpid, milky emulsion, which filters readily, yielding an opalescent filtrate. Other slight differences in the properties of *a*- and *b*-legumins are described, which indicate that *b*-legumin is not formed from *a*-legumin by the action of acid, alkali or water but is a distinct protein.

C. J. WEST.

The distribution of the aluminium ion in plants. JULIUS STOKLASA, J. SEBOR, W. ZDOBNICKY, F. TYMICK, O. HORAK, A. NEMEC AND J. CWACH. *Biochem. Z.* 88, 292-322 (1918); *J. Chem. Soc.* 114, I, 475.—Al is widely distributed in plants. A large no. of analyses is tabulated. The xerophytes contain only small amts. of Al, whereas the hydrophytes and hygrophilic plants contain relatively large quantities. The mesophytes when growing on dry soils are very poor in Al, but contain an appreciable quantity when growing on marshy ground.

C. J. WEST.

**Physiological significance of potassium in plants.** TH. WEEVERS. *Biochem. Z.* 89, 281-2(1918); *J. Chem. Soc.* 114, I, 518.—A final reply to Stoklasa. Cf. *C. A.* 2, 1317; 12, 165. C. J. WEST.

**Biochemistry of seaweeds.** HARALD KYLIN. *Z. physiol. Chem.* 101, 236-47 (1918); *J. Chem. Soc.* 114, I, 476.—Various kinds of algae have been examd. for the presence of sol. carbohydrates and laminarin. Of 8 species of brown algae, two, *Desmarestia aculeata* and *D. viridis*, contained laminarin, while in all the % of sol. carbohydrates was small. Four species of *Floridæ* were found to contain trehalose but not mannitol. Of the *Chlorophyceæ* investigated, *Cladophora rupestris* contained 15% of sol. carbohydrates, including sucrose and a levorotatory polysaccharide resembling inulin. C. J. WEST.

### E. NUTRITION.

PHILIP B. HAWK.

#### NORMAL.

**The value of skim-milk and meat scraps for white plymouth rocks.** A. G. PHILIPS. *Purdue Agr. Expt. Sta., Bull.* 218, 20 pp.(1918).—The expts. consisted of feeding to 3 lots of pullets a mixed grain and mash feed of bran and shorts; 1 lot was fed in addition meat scraps, and a 2nd skim-milk, the 3rd serving as a check. Eggs from pullets fed meat scraps were more fertile but had weaker hatching power than eggs from those fed skim-milk. The egg production per year averaged 140.2 eggs per pullet when fed skim-milk, 135.9 for those fed meat scraps and 61.2 for those serving as checks. J. J. SKINNER.

**Nuclein metabolism. V. Destruction of the purine ring by bacteria in the human intestine.** S. J. THANNHAUSER AND G. DORFMÜLLER. *Z. physiol. Chem.* 102, 148-59(1918); *J. Chem. Soc.* 114, I, 513; cf. *C. A.* 8, 3580, 3581; 10, 182; 12, 929.—After 20 days' incubation of adenosine, guanosine or inosine with a culture of bacteria from the human intestine, from 60 to 100% of the N in the nucleosides is found to have been converted into  $\text{NH}_3$ . These results are in harmony with and explain the observation that the purines in ingested nucleic acid are not quantitatively excreted in the form of uric acid, but to a certain extent undergo degradation in the body and are eliminated as urea (doubtless through the intermediate formation of ammonia by the action of the intestinal bacteria). C. J. WEST.

### F. PHYSIOLOGY.

ANDREW HUNTER.

**Shock and its control.** W. B. CANNON. *Proc. Am. Physiol. Soc., Am. J. Physiol.* 45, 544(1918).—The observations were made at a casualty clearing station in France, a few miles back from the front lines trenches. The main conclusions are: (1) There is a discrepancy between the red counts, hemoglobin and hematocrit readings of venous and capillary blood in shock cases, indicating a concn. of blood in capillaries. (2) The shock cases, when received at the clearing station, have a diminished alk. reserve (an acidosis, in the Van Slyke sense). (3) A rough correspondence exists between the degree of acidosis and the degree of depression of the blood pressure. (4) Surgical operation, in many cases, lowers the alk. reserve, and in shock cases operation may in a short time reduce the reserve to a serious degree. (5) In shock cases the low alk. reserve and low arterial blood pressure are made worse by the necessary operation. (6) By the injection of  $\text{NaHCO}_3$  intravenously at the start of the operation both the

unfavorable effects of the operation are obviated—the pressure is higher at the end than at the start and the alk. deficiency is abolished. G. MCGUIRE.

Some reactions in the development of shock by diverse methods. J. ERLANGER, *et al. Proc. Am. Physiol. Soc., Am. J. Physiol.* 45, 546(1918).—"Shock supervenes in consequence of extensive tissue damage, not necessarily traumatic in origin." In all forms of shock there occurs a diminution in plasma vol. There is often a reduction in the vol. of blood as a whole. Usually the vasoconstriction is affected although it is possible to have shock with a normal vasoconstriction. In the mechanism of shock three factors predominate: (1) Generalized transudation, caused by slowing of the blood stream to the point of damaging the cells. (2) Low arterial reserve. (3) Diminished alk. reserve. Sometimes one, sometimes another, of these factors predominates.

G. MCGUIRE.

The blood volume changes in shock and the modification of these by acacia. H. S. GASSER, W. J. MEEK AND J. ERLANGER. *Proc. Am. Physiol. Soc., Am. J. Physiol.* 45, 547(1918).—"The forms of shock studied were those produced by exposure of the intestine, injection of adrenaline, and temporary partial occlusion of the vena cava or the aorta. The findings in all cases were essentially the same." The injection of acacia reduced the decrease of plasma from about 22.2% of the total blood vol. to 7.4%. "Loss of plasma accounted for all the decrease in blood vol. in one-third of the cases." It is concluded that the decrease in plasma loss upon the injection of acacia is most likely to be found in decreased permeability of the vessels. In the amts. used the colloidal osmotic pressure of the plasma would increase about 14.5%. This would act in the direction of absorption, but the blood counts gave no evidence that any appreciable expansion of the plasma vol. from the tissues takes place in one hr. The possibility that acacia acts as a Ca salt in decreasing the permeability of the vessels is suggested.

G. MCGUIRE.

The influence of the increase of osmotic pressure of the liquids of the body on the different cell substrata. S. DE BOER. *Proc. Acad. Sci. Amsterdam* 21, 151-7(1918).—Osmotic pressure was increased as follows: by placing frogs in Ringer soln. containing 18 g. NaCl so that all but the head and back were immersed, by immersing in a 1.38% soln. of glucose, by placing frogs in a dry bottle and passing dry air through it, and by replacing the blood from the vena abdominalis with the NaCl soln. used above. Under all 4 conditions the same phenomena of coma, passivity, and lack of reaction were observed, the respiration showed the periodicity known as the Cheyne-Stokes reaction and the surface of the pupils had the appearance of cataract. All the phenomena disappeared when the animal was placed in water. The cataract is attributed to a congelation of albuminous substances in consequence of the increase in the concn. of the body fluids.

F. POWDERMAKER.

Tropistic action of blood vessels on the migration of chromatophores. H. D. TAYLOR. Rockefeller Inst. *J. Exp. Med.* 29, 135-8(1919).—"The migration of the chromatophores of the yellow sac of *Fundulus heteroclitus* seems to be chemotropic in character. The determining factor seems to be a high tension of O or a comparatively low concn. of H ions.

C. J. WEST.

Agglutination of red blood corpuscles and the Hofmeister series. W. RADSMAN. *Biochem. Z.* 89, 211-9(1918); *J. Chem. Soc.* 114, I, 511-2.—Blood corpuscles, suspended in a large amt. of isotonic soln. of dextrose, readily agglutinate on addition of a small amt. of a salt; 0.04% of NaCl is sufficient to bring about this phenomenon. The anions, in their activity as regards this agglutinative effect, follow the order of the Hofmeister series and this indicates that some hydrophil colloid plays a part in maintaining the stability of a suspension of the corpuscles.

C. J. WEST.

**Possibilities of fractional gastric analysis.** MARTIN E. REHFUSS. Jefferson Med. Coll. *J. Am. Med. Assoc.* 71, 1534-7(1918).—The following conclusions are stated: "Fractional gastric analysis alone can reveal the evolution of gastric digestion. Gastric digestion, whether normal or pathol., consists of a series of constantly changing phases. Certain phases are normal, certain are obviously pathol. Normal gastric physiology consists in a rhythmic series of cycles in which we may differentiate the digestive and the interdigestive periods. In health, they succeed each other regularly; in disease, their sequence is seriously interfered with. The digestive cycle is the response of the stomach to a definite stimulus. The response is partly psychic and partly chem., but in its essential characteristics it differs from the interdigestive phase. There is always a physiol. active secretion in the stomach but the characteristics of the two periods are very different. The digestive secretion persisting into the interdigestive period is pathol. Studies of healthy men indicate that there is no acidity in disease which cannot be encountered in health, and the diagnostic value of high acidity must be very carefully worked out. Forty-five % of more than 800 normal cases gave a total acidity of 100 in excess. Normally, we point out three different secretory types. Pathologically every possible variation in secretory output occurs. At present it seems that there are many possibilities in the analysis of each variety of curve. It is at this point that circumstantial evidence by the study of the protein curve, pus, blood, mucus, bacteria and tryptic regurgitation may throw light on the subject. In every case the extragastric as well as the gastric causes must be reviewed. The gastric response may be shortened, delayed or exaggerated. It may be accompanied by the most marked variations in secretory and acid concn. output. It may be altered by the addition of pus, blood, mucus, and bacteria in every possible way, and these variations may occur only at certain portions of the curve, emphasizing the necessity for complete examn. The investigation of psychic secretion, tryptic and biliary regurgitation, hypersecretion, protein concn. and secretory velocity, and of the evidence of pathol. material is full of promise."

L. W. RIGGS.

## G. PATHOLOGY.

H. GIDEON WELLS AND ANDREW HUNTER.

**The influence of active normal serum (complement) upon meningococci. I. The opsonic activity of fresh normal serum alone and in combination with antimenigitis serum for meningococci.** J. A. KOLMER, I. TOYAMA AND T. MATSUNAMI. Univ. of Pa. *J. Immunology* 3, 157-200(1918).—The bactericidal activity *in vitro* of different antimenigitis sera was found to be quite low. Fresh or active antimenigitis serum was somewhat more bactericidal than the same serum after inactivation by heating at 60° for 30 min. The bactericidal activity of horse antimenigitis and normal human and guinea pig serum is largely independent of complemental bacteriolysis. The addition of active normal human and guinea pig to antimenigitis serum sometimes increased the bactericidal activity of the latter. Whole human and guinea pig blood was found slightly more bactericidal than the serum alone. Normal human and guinea pig serum frequently agglutinate meningococci in final dilns. up to 1:4, but not in higher dilns. These sera were practically without demonstrable protective value in mice infected with virulent meningococci, although the addition of these normal sera to antimenigitis serum appeared in some expts. slightly to increase the protective power of the latter. It is suggested as worthy of a clinical trial to complement the antimenigitis serum by the addition of active human or guinea pig serum prior to intraspinal injection and particularly in the treatment of severe and serum-resistant infections.

GEO. T. CALDWELL.

**The relation of the meningococcal activity of the blood to resistance to virulent meningococci.** T. MATSUNAMI AND J. A. KOLMER. Univ. Pa. *J. Immunology* 3,

201-12(1918).—Bactericidal tests with a strain of virulent normal meningococci and the blood of adult white mice, adult rabbits and young and older guinea pigs have shown that the blood of rabbits possesses more bactericidal activity; the blood of old guinea pigs was found somewhat more bactericidal than the blood of young guinea pigs and white mice. The blood of young guinea pigs was generally slightly more bactericidal than the blood of adult white mice. In the virulence tests consisting in the intraperitoneal injection of the same culture in graded doses and according to body wt., rabbits were found more resistant; young guinea pigs were about as susceptible as adult mice while older guinea pigs were somewhat more resistant than either. It seems that there is a general parallelism between the meningococcal activity of the blood and resistance to meningococci and at least one factor in natural immunity to the meningococcus is the presence of bactericidal substance in the blood. The meningococcal activity of blood of children is somewhat less than that of adults. It is probable that certain persons possess sufficient natural immunity to the meningococcus to afford protection against meningitis and it is highly desirable to discover a simple and accurate clin. test or measure of this resistance comparable to the Schick test for antitoxic immunity in diphtheria as a means of encouraging active immunization with meningococcus vaccines.

GEO T. CALDWELL.

The study of problems of immunity by the tissue culture method. I. A study of the cells and blood plasma of animals which are naturally resistant and others which are susceptible to diphtheria and tetanus toxins. Y. SUZUKI. *St. Louis. J. Immunology* 3, 233-46(1918).—The natural immunity of rats for diphtheria toxin and chickens for tetanus is due to two factors—a special resistance of at least certain of the cells of these animals, and the existence of neutralizing substances in their plasma. The plasma of these animals protects against lethal doses of toxin not only their own cells but also the cells of susceptible animals. Thus far heart muscle, ovary and connective tissue cells have been studied. As sufficient expts. have not been made to give quantitative results, a further investigation into the nature of the cellular resistance and the mechanism of neutralization as indicated in the plasma tests can be accomplished by this method. II. The tissue cultures as a means for quantitatively estimating toxin and antitoxin and determining the distribution of antitoxin in passively immunized animals. M. T. BURROWS AND Y. SUZUKI. *Ibid* 219-32.—It has been shown that chicken's tissues are sensitive in the tissue culture to the action of diphtheria toxin where this is added to the medium. Antitoxin when injected into chickens protects them against lethal doses of toxin. It seemed evident that the tissue culture method would be of use for the quant. standardization of toxins. In the expts. reported the tissue cells of young chickens and chick embryos were studied. The medium consisted of plasma prepd. from the blood of young or adult chickens, dild. with the substances to be tested. Fragments of tissue or single cells are placed on the surface of a cover glass and covered with a layer of medium about 0.5 mm. in thickness. A hollow slide rimmed with vaseline is inverted over the cover so that the tissue and plasma mixt. is sealed in the hollow air chamber. After clotting had taken place the slides were inverted and the cover glasses sealed more completely by running them with paraffin. Only diphtheria toxin was investigated, but its study indicated the value of the method for detg. the neutralizing power of a plasma for any given toxin.

GEO. T. CALDWELL.

Typhus fever. Observations on a serological test (Weil-Felix reaction). C. M. CRAIG AND N. H. FAIRLEY. *Lancet* 1918, II, 385-6.—Typhus serum possesses the power of agglutinating certain intestinal organisms. The stock culture here used is an organism of the strain known as X 19; it is a short Gram-negative, slightly motile bacillus, which grows under aerobic conditions only. It produces indole freely and acid without

clot formation in milk. A rapid agglutination in a diln. of  $1/10$  while not absolutely reliable is sufficiently suspicious to justify isolation of the case. Frequently the reaction appears early in the disease and as a rule rapidly increases in titer. GEO. T. CALDWELL.

The chemistry of diphtheria antitoxin—a review. ALBERT C. CRAWFORD AND MARJORIE G. FOSTER. *Am. J. Pharm.* 90, 765-82(1918). W. G. GAESSLER.

Electrolytic theory of dental caries. II. PAUL R. MANNING. *Dental Cosmos* 61, 21-7(1919); cf. *C. A.* 12, 937.—The dentin may function as a semipermeable membrane. When a plate of dentin 0.25 mm. thick was used as a membrane between a soln. of an electrolyte and distd. water, water passed through the plate in the direction of the soln. of the electrolyte. Diffusion of salts through the plate was not obtained. Enamel was apparently capable of assuming an electrical polar quality when immersed in a soln. of electrolytes. Presence of water was found essential for the inception and progress of dental caries. JOSEPH S. HEPBURN.

Constituents of alcoholic extracts of organs which are active in Wassermann's reaction. FRITZ SILBERSTEIN. *Biochem. Z.* 88, 1-12(1918); *J. Chem. Soc.* 114, I, 464-5.—Exts. of incompletely autolyzed organs are more active as "antigens" in the Wassermann reaction than are exts. of the fresh organs. If autolysis, however, proceeds too far, the exts. become inactive. Neither the fraction sol. in alc., but insoluble in ether (soaps), nor the fractions sol. in alc., ether and acetone (fatty acids, fats, and cholesterol) of either fresh or autolyzed livers give a reaction as marked as the whole ext. The fraction from the fresh organs containing the lipoids gives as good results as the whole ext. of the partly autolyzed organ. The best reaction, however, is obtained by a mixt. of the lipoid fraction with equiv. amts. of the fraction containing the soaps, fatty acids and cholesterol. Treatment of the organ with trypsin or steapsin destroys its power of giving antigens; this function of the organs is not, however, altered by their treatment with pepsin-HCl, ricin-lipase, or with dil. acid or alkali.

C. J. WEST.

Effect of feeding sugar upon the esterase content of the blood serum and organs in phosphorus poisoning. J. P. SIMONDS. Northwestern Univ. Med. School. *J. Exp. Med.* 28, 663-72(1918).—Clear, filtered glycerol exts. of chopped liver, spleen or kidney contain an esterase. The esterase content of exts. of liver and spleen of the normal dog is reasonably const. It does not appear to vary to any great extent from the normal in poisoning with  $\text{CHCl}_3$  and P. Feeding large quantities of sugar and increasing the amt. of glycogen in the liver is accompanied by a marked increase in the esterase content of that organ. This increase is also evident in P-poisoned animals which have been fed a large amt. of sugar. The feeding of sugar does not prevent the increase in esterase in the blood serum of animals poisoned with P. The esterolytic power of exts. of the kidney varies considerably in different dogs. C. J. WEST.

The peptolytic power of liver, spleen, and kidney in poisoning with phosphorus and chloroform. J. P. SIMONDS. Northwestern Univ. Med. School. *J. Exp. Med.* 28, 673-9(1918).—Glycerol exts. of liver, spleen and kidney contain an ereptic enzyme capable of splitting peptone into amino acids. Poisoning with P appears to reduce this ereptic power of the liver and to a less extent that of the kidney. Poisoning by  $\text{CHCl}_3$  appears to have no appreciable effect upon the ereptase content of these organs. Feeding of sugar to normal animals has little or no effect upon this power, but feeding before and after P poisoning appears to prevent the reduction of ereptic power of the liver. C. J. WEST.

The phosphorus in organic combination in human urine. Observations in acute yellow atrophy of the liver. JOH. FEIGL. *Biochem. Z.* 89, 126-34(1918); *J. Chem. Soc.* 114, I, 514.—This is chiefly a review of the literature and of methods.

C. J. WEST.

**Studies in cholelithiasis. I. The disturbances of the cholesterol metabolism as a factor in gallstone formation.** M. A. ROTHCHILD AND A. O. WILENSKY. *Am. J. Med. Sci.* 156, 239-47(1918).—A summary of the knowledge of cholesterol metabolism. The principal data on bile chemistry have been derived from studies on pathological cases. Normal bile, as detd. by R. and W., contains 20-80 mg. cholesterol per 100 cc. bile. In hypercholesterolemia, 850 mg. bile cholesterol percent may occur. Blood cholesterol in normal cases was found by these investigators to be 150-80 mg. %. A fairly definite relation was found to exist between food and cholesterol content of bile and blood. A review is given of the present state of the theories of cholesterol concretion formation, cholesterolemia and pregnancy and bacterial factors. II. The clinical relationships of the cholesterolemia to the pathological process. ABRAHAM O. WILENSKY AND MARCUS A. ROTHCHILD. *Ibid* 404-14.—A study of 70 cases. Normal blood cholesterol was found in a variety of diseases involving calculi, incomplete bile-duct obstruction, empyema of the gall-bladder, etc. Owing to the influence of diet, diseases such as nephritis, diabetes, atherosclerosis, pregnancy, etc., the cholesterol content varies. In heightening the blood cholesterol figure, it is not possible to utilize cholesterol as a diagnostic factor, except rarely as in differentiating between jaundice due to biliary obstruction and that caused by cirrhosis of the liver.

WITHROW MORSE.

#### H. PHARMACOLOGY.

ALFRED N. RICHARDS.

**Trinitrotoluene poisoning with a record of five cases.** ALBERT WM. GREGORSON. London. *Glasgow Med. J.* 8, 65-78(1918).—A jaundice is caused which resembles the jaundice of acute liver atrophy. There is a reabsorption of bile which causes a severe anemia, fall in % of hemoglobin and extreme polymorphonuclear leukopenia. Toluyl-enediamine is the active agent producing the jaundice. In some cases the principal paths of absorption were the lungs and stomach. The poisoning produces first gastrointestinal disturbances and peripheral neuritis followed by headache, anemia and jaundice.

F. HULTON-FRANKEL.

**The antagonistic action of salts.** L. W. H. VAN OYEN. *Biochem. Z.* 87, 418-24 (1918); *J. Chem. Soc.* 114, I, 472.—A preliminary account is given of attempts to correlate physical properties of salts in soln. with their biological action. It is shown that Cl is adsorbed less by various adsorbents from solns. containing Na, K, and Ca chlorides than from a soln. of NaCl alone. The proportions of the various cations in the expts. were those used by Osterhout in his biological expts. Expts. are also described on diffusion of Cl through a dialyzer from solns. of NaCl alone or mixed with KCl and CaCl<sub>2</sub>.

C. J. WEST.

**The biological action of convolvulin and jalapin.** G. HEINRICH. *Biochem. Z.* 88, 13-34(1918); *J. Chem. Soc.* 114, I, 467.—These substances are like the saponins and agaricin in that they exert a hemolytic action when they are in neutral soln. They are very sensitive to alkalis, however, and rapidly lose the hemolytic action in the presence of a slight excess of alkali. The hemolytic action could only be demonstrated *in vitro*, but not *in vivo*, as no blood appeared in the urine after intravenous or subcutaneous injection. Neither was any purgative action observed. They are both specific poisons for fish. For purgative action, direct contact of the glucosides with the mucous membranes of the intestines is necessary. This action is also lost when the substances are treated with alkali and the hemolytic action can therefore be used in testing the value of the preps. as drugs. They are less sensitive to the action of mineral acids, as, in spite of the hydrolysis which ensues, the purgative action is not lost. In this respect, they are similar to the saponins. Like the saponins, they are only incompletely resorbed in the alimentary tract and appear unchanged in the feces.

C. J. WEST.

**Influence of temperature on the capillary activity of narcotics.** B. VON ISSERKUTZ. *Biochem. Z.* 88, 213-8(1918); *J. Chem. Soc.* 114, I, 467-8.—Temp. alters the narcotic activity of indifferent narcotics in the same direction as it alters their capillary activity. Increase and decrease of the narcotic activity of the 6 substances investigated by H. H. Meyer can be ascribed not only to the differences produced in their distribution between  $H_2O$  and org. solvents on warming, but also to increase or decrease of their capillary activity. In the case of other poisons, increase of temp. can cause diminution of capillary activity, while their potency is enhanced. C. J. WEST.

**Narcosis and oxygen concentration.** B. VON ISSERKUTZ. *Biochem. Z.* 88, 219-31 (1918); *J. Chem. Soc.* 114, I, 462-3.—The action of narcotics is independent of the O concn., and there is no marked difference in their action on tadpoles in water rich and poor in O. During narcosis the O respiration of tadpoles diminishes from 18 to 40%. Ethylurethan and alc. in narcotizing doses cause the same amt. of diminution. KCN diminishes O respiration to the extent of 30-40% without causing paralysis. Increased partial pressure of O can increase O respiration of the tadpoles without inhibiting the action of narcotics; in fact, the O consumption of the animals under deep narcosis in water rich in O is greater than that of the non-narcotized animals in water with the normal amt. of O. C. J. WEST.

**Action of chlorates on the blood of man and certain animals.** EGBERT CAESAR. *Biochem. Z.* 89, 1-26(1918); *J. Chem. Soc.* 114, I, 512.—Details are given as to the concns. in which  $KClO_3$  exerts an injurious effect on the blood, giving rise to the formation of methemoglobin. The general conclusion is drawn that  $KClO_3$  can act toxically when taken *per os* and that it should not be used indiscriminately in tooth powders and analogous preps. The astringent action of  $Al(ClO_3)_3$  is due to the Al ion. A detailed criticism is given of a commercial prepn. of chlorates, known as Mallebrein's. C. J. WEST.

**Action of pilocarpine on respiratory metabolism and the gas content of the blood.** G. KELEMAN. *Biochem. Z.* 89, 135-55(1918); *J. Chem. Soc.* 114, I, 511.—The increased secretory activity of the salivary glands produced by pilocarpine is accompanied by an increased metabolism of energy (about 10%). There is also produced at the same time an increased  $CO_2$  content in the blood, both venous and arterial. There is no evidence, however, of an increased "secretion" of  $CO_2$  by the blood. C. J. WEST.

**The biochemical behavior of aminomethyl hydrogen sulfite.** E. SALKOWSKI. *Biochem. Z.* 89, 178-98(1918); *J. Chem. Soc.* 114, I, 514.— $H_2NCH_2OSO_2H$  yields HCHO in distn. of an aq. soln. and also, but very slowly, when it is kept in  $H_2O$  at ordinary temp. Expts. with urine and meat indicate that it is of little value as an antiseptic. No HCHO could be detected in the urine after the administration of the acid to a rabbit. When administered to a dog, part appears, from the increase of the neutral S in the urine, to be excreted unchanged. Indican disappears from the urine during administration and this fact seems to indicate that the sulfite acts as an intestinal antiseptic. C. J. WEST.

**The influence of temperature on the strength of action and surface activity of narcotics.** RUDOLF UNGER. *Biochem. Z.* 89, 238-78(1918); *J. Chem. Soc.* 114, I, 515.—The influence of changes of temp. on narcotic activity of various substances such as chloral hydrate, salicylamide, benzamide, nomaactin and EtOH was investigated, the subjects of the expt. used being tadpoles, the fish *Leuciscus*, and the sciatic nerve of frogs. In some cases, increase of temp. increased and in others it diminished narcotic activity. These changes could not always, however, be correlated with changes in the distribution of the narcotic between oil and water, as would follow from the Overton-Meyer theory, or with the change in surface tension of the solns.

Account has to be taken in investigations of this character of the effect of temp. changes on the general metabolic activity. C. J. WEST.

**The influence of atropine on respiratory metabolism and the blood gases.** GEORGE KELEMAN. *Biochem. Z.* 89, 338-49(1918); *J. Chem. Soc.* 114, I, 511.—There is a marked diminution of the respiratory metabolism of dogs after intravenous injection of atropine, which effect can be antagonized by the simultaneous injection of pilocarpine. The increased gaseous metabolism produced by pilocarpine can be diminished by atropine and the diminished gaseous metabolism produced by the latter alkaloid can be increased by the subsequent injection of the former. The content of the blood in  $\text{CO}_2$  is diminished by injection of atropine. This diminished output of  $\text{CO}_2$  produced by injection of atropine, already mentioned, is due, therefore, not to a diminished secretion of this gas by the lungs but to a general diminution of its production.

C. J. WEST.

**Relative irritant properties of the chlorine group of antiseptics.** G. E. CULLEN AND F. D. TAYLOR. Rockefeller Inst. *J. Exp. Med.* 28, 681-99(1918).—The use of the ears of rabbits is proposed in testing the irritant effect of antiseptics. It is necessary, because of individual variations, to use solns. having definite irritant actions as constants. 0.5%  $\text{NaClO}$  solns. have minimum irritant effects over a range of alkalinity of from about 100 to 1000 times that of  $\text{H}_2\text{O}$  ( $p_{\text{H}}$  above 9-10). Solns. may be adjusted within these limits by use of endpoints of powdered phenolphthalein or of alc. solns. of *o*-cresolphthalein or phenolphthalein.  $\text{NaClO}$  solns. kept within the above range by either borate or carbonate buffer salts (Dakin soln.) show the same irritant effect, whether made from  $\text{Ca}(\text{OCl})_2$  and  $\text{Na}_2\text{CO}_3$ , from  $\text{Cl}$  and  $\text{Na}_2\text{CO}_3$  or electrolytically. Solns., however, that have an alkalinity of less than that indicated by the endpoint to alc. phenolphthalein ( $p_{\text{H}}$  8.5-8.8) or greater than that indicated by the endpoint to powdered phenolphthalein are intensely irritating. 0.5%  $\text{NaClO}$  solns. from which most of the  $\text{Ca}$  has been pptd. or  $\text{Ca}(\text{OCl})_2$  solns. of equiv.  $\text{HOCl}$  concn. are only slightly irritating. 2% chloramine-T soln. has no irritant action. 5% dichloramine-T in chlorosane or chlorosane alone irritates rabbit ears to a slight degree only.

C. J. WEST.

**Action of chlorinated antiseptics on blood clot.** H. D. TAYLOR AND M. G. STEBBINS. Rockefeller Inst. *J. Exp. Med.* 29, 125-31(1919).—Chlorinated antiseptics have no power to penetrate blood clots and destroy bacteria contained therein.

C. J. WEST.

**Effects of various systemic agents on superficial hemorrhage.** PAUL J. HANZLIK. Western Reserve Univ. *J. Pharmacol.* 12, 119-28(1918).—The most effective hemostatic agent on superficial bleeding by systemic (intravenous) administration was adrenaline; tyramine somewhat less; pituitary ext. was variable. Fatal doses of ergot and digitalis (1 expt. each) also lessened and arrested, respectively, the bleeding. The effects of the following systemically on bleeding are roughly parallel to the changes in blood pressure: coagulen (Ciba), cephalin (Howell), thromboplastin (Squibb), horse serum, stypticin, gelatin, saline, emetine and possibly peptone. Nitrite and hydrastis increased bleeding with a fall in blood pressure. The results with the thromboplastic agents might be different with prolonged administration.

C. J. WEST.

**Effects of various agents on superficial hemorrhage and the efficiency of local hemostatics.** PAUL J. HANZLIK. Western Reserve Univ. *J. Pharmacol.* 12, 71-117(1918).—Beginning with the most efficient, the order of efficiency of the more important of all the hemostatic agents tested is adrenaline, pituitary ext., tyramine, acetic acid,  $\text{FeCl}_3$ , quinine-urea-hydrochloride, tannin,  $\text{NaHCO}_3$ ,  $\text{BaCl}_2$ , cane sugar,  $\text{NaCl}$ . A no. of other agents, which were tried, can lessen local hemorrhage in variable

degrees, but on the whole they are inferior and undesirable for various reasons. The following, among the more important of this class and for which hemostatic claims have been made, were found to increase bleeding on local application: cotarnine salts (stypticine and styptol), antipyrine, peptone, emetine, sometimes alum. Orthoform (1% soln.) also quite markedly increased local bleeding. Under the conditions, cephalin, coagulen and thromboplastin were all variable, or did not affect the course of bleeding.

## I. ZOÖLOGY.

R. A. GORTNER.

Pigmentation of a clypeastroid, *Mellita sesquiperforatus* Leske. W. J. CROZIER. Bermuda Biol. Sta. *Am. Nat.* 52, 452-6 (1918).—Detailed reports of expts. with this organism are given. "Evidence afforded by intracellular substances capable of behaving as indicators of acidity, shows that the tissues of marine animals are much more acid (less alk.) than sea water." The green color is produced when the tissue fluids become more alk. than usual.

L. W. RIGGS.

Toxic action of potassium cyanide and its relation to the state of nutrition and age of the cell as shown by *Paramecium* and *Didinia*. BARBARA LEE LUND. *Biol. Bull.* 35, 211-31 (1918).—The following summary is given: An attempt was made to discover what factor or factors are responsible for the observed differences among individuals of a pure line of *Paramecia* and *Didinia* living in the same culture medium, e. g., hay infusion. What are the differences in a protozoan cell which cause differences in response to apparently identical external conditions at different times? Survival time (resistance) of these organisms in solns. of KCN was selected and used as an index because of the generally supposed relation of the toxic action of KCN and the rate of oxidation in cells. All data on survival time were obtained by observation on individual cells and not by estg. the av. survival time of large numbers of the cells, as is usual in such expts. In this way the variation in resistance of the cell at different times during the period between cell divisions was followed accurately and is summarized by curves. The cessation of movement of *Paramecium* is a less variable endpoint than cytolysis for detg. the death point in KCN solns. *Paramecia* can be cultivated in pure line mass cultures in tap water when fed compressed yeast. In this way the chem. compn. of the medium and food can be kept more const. than has been possible previously in work on *Paramecium*. Resistance of *Paramecia* to KCN when allowed to feed on bacteria shows a marked increase, and when fed on yeast the resistance increases to a smaller degree from the time of division up to the following division. The resistance of *Didinia* to KCN when fed with *Paramecium* increased from the time of completion of division until a max. was reached sometime previous to the second division, and then gradually fell before the second division. This rhythm is directly comparable with that found by Lyon and others in echinoderm eggs (cf. C. A. 5, 1921). When *Paramecia* and *Didinia* are prevented from obtaining food the resistance to KCN gradually decreases below its value at the completion of division. Starvation of sister cells of *Didinia* results in a decrease in difference of survival time in KCN. This original difference in sisters is apparently due to the fact that the food content is not always distributed equally to the daughter cells at division. In *Paramecium* the distribution of food is practically equal, and here the av. difference in survival time between sisters is the same immediately after division as it is after a period of 24 hrs. The differences noted above are attributed to a change in the permeability of the cell. Penetration of KCN into the cell and hence its toxic action as a measure of survival time, is dependent upon the permeability of the cell at different times. On this assumption rhythm in susceptibility depends primarily upon rhythm in permeability.

L. W. RIGGS.

**The influence of oxygen on metabolism. I. Experiments on meal-worms.** TORBJORN GAARDER. *Biochem. Z.* 89, 48-93(1918); *J. Chem. Soc.* 114, I, 512.—The metabolism of the *Tenebrio chrysalis* is independent of the O tension of the atm. as long as the O tension of the tissues is positive. As the O tension of the atm. sinks, the gradient between the O tension of the tissues and the atm. remains const. until the former tension becomes zero. With further diminution of the tension of the O of the atm. beyond this point, the gradient of O tension between the tissues and atm. sinks, and the O consumption of the chrysalis diminishes. Numerous numerical data are given in support of these statements. The expts. were carried out by means of a modified micro-respirator of Krogh. If the chrysalis is allowed to remain in an atmosphere so poor in O that the metabolism is subnormal, certain anaerobic processes take place. On removing the animal to an atm. of normal O content, the metabolism remains subnormal for some time; it then increases and becomes greater than normal. This is apparently due to the destruction of products formed during the anaerobic conditions.

**II. Experiments with carp.** *Ibid* 89, 94-125; *J. Chem. Soc.* 114, I, 512-3.—An app. is described for passing water with known O content through gills of fish and estg. the consumption. It is found that there is very slow increase in O consumption with increasing tension of the O dissolved in the water. The increase is so small that the conclusion is drawn that the changes in O tension in water which take place normally are without any appreciable effect on the metabolism. There is a linear relationship between O consumption and the O tension of the water passing the gills; that is, the O consumption is in accordance with laws governing the absorption of gases by a liquid and the increase of the consumption can be explained by assuming that the oxygen dissolved physically in the blood is utilized.

C. J. WEST.

## 12. FOODS.

W. D. BIGELOW and F. F. FITZGERALD.

**Influence on health of antiseptics added to food products.** T. J. RUMI. *Anales soc. quim. Argentina* 6, 210-4(1918).—R. discusses a paper by P. Brouardel. In considering this question it is not always sufficiently kept in mind that certain preservatives ingested with food in small daily amts. for a long time may by their toxicity produce symptoms quite distinct from those which ensue after a limited no. of medicinal doses in larger amt. The matter must, furthermore, be decided on the basis of the total daily amt. ingested regardless of the proportion, however small, of preservative which may be present in any given food product. The fixing of a max. legal proportion of preservatives, as suggested by certain food interests, is not feasible in view of the fact that the min. toxic dose is dependent not only on the nature of the substance employed but also on such varying factors as the age, state of health, etc., of the individual. In view of the above and the fact that exact proof as to the cause of injury to health is often difficult in cases where there is strong probability that such injury to health is due to preservatives in food, R. concurs with B. that debated questions of injuriousness to health should be decided in favor of the public and that prohibition of the use of preservatives in foodstuffs should be more sweeping in character.

H. S. PAINÉ.

**Rules and regulations of the Secretary of Agriculture under the food products inspection law of Oct. 1, 1918.** ANON. U. S. Dept. Agr., Office of Sec., *Circ.* 120, 8 pp.

J. J. SKINNER.

**Utility of blanching food in food canning—effect of cold shock upon bacterial death rates.** EVA M. BRUETT. *J. Ind. Eng. Chem.* 11, 37-9(1919).—The belief is

disproved that cold shock after heating so injures the vitality of the bacteria as to make them more susceptible to subsequent heating. The organism used was *Bacillus pseudotetanicus* (Kruse) Migula. Several tables show that the velocity coeff. of the death rate of shocked and unshocked bacteria is nearly const. The value of blanching is the cleansing action of the process which leaves a smaller number of spores in the canned product.

DOROTHY B. SCOTT.

The determination of milk sugar. GRIMMER AND E. URBSCHAT. *Milchwirtschaft. Zentr.* 46, 257 (1917); *Biedermanns Zentr.* 47, 222-3 (1918).—Cow and goat milk were deproteinized by means of a colloidal  $\text{Fe}(\text{OH})_3$  soln. instead of  $\text{CuSO}_4$  as in the Ritt-hausen method, and the results of detns. of sugar were found to agree very closely with those obtained by use of  $\text{CuSO}_4$ . Twenty-five cc. milk are brought to 400 cc. with  $\text{H}_2\text{O}$  and the colloidal  $\text{Fe}(\text{OH})_3$  is added from a buret till the supernatant fluid, after settling of the ppt., appears clear and colorless. Ten cc. of cold satd.  $\text{NaF}$  soln. are added to the mixt. and the whole is diluted to 500 cc. After filtration sugar is detd. in 100 cc. by the usual Fehling method.

ALBERT R. MERZ.

Table for sorting of milk samples. L. J. HARRIS. *Analyst* 43, 375-7 (1918).—This table allows the analyst to see at a glance from the sp. gr. and total solids whether the milk is deficient in fat or solids-not-fat. The table is calcd. on Richmond's formula.

H. A. LEPPEL.

Additive factors for the calculation of fat in milk from the specific gravity and total solids. L. J. HARRIS. *Analyst* 43, 263-7 (1918).—In order to obtain rapidly where many routine samples of milk are analyzed H. submits two tables of factors for calcg. the fat when the total solids and sp. gr. are known. Formulas used in the prepn. of the table are given.

H. A. LEPPEL.

The reductase test in the service of cream production. A. E. SANDELIN. *Helsingfors. Molkerei-Ztg.* 27, 281-2, 290-1, 298-9 (1917); *Biedermanns Zentr.* 47, 140-3 (1918).—The reduction periods of the whole milk, skim milk and cream of test samples which were obtained and handled with the greatest possible protection against bacterial infection were detd. and their bacterial contents ascertained or calcd. Cultures were planted on gelatin with the fluids according to the method of Barthel and Orla-Jensen (*C. A.* 7, 1063, and *Kgl. Landbruks-Akad. Handl. Tid.* 1912, p. 13) kept at room temp. and counted after 7 days. The reduction periods were detd. according to the method of the same authors, using Blauenfeldt and Tvedes plates. Uniform distribution of acids was insured by previous vigorous shaking. The fat content of the whole milk and the cream was detd. according to Gerber, that of the skim-milk by Roesse-Gottlieb's method. The % of cream was calcd. by the formula  $x = (Vf - Mf) / (Rf - Mf)$ . ( $Vf$  = fat in whole milk,  $Mf$  = fat in skim-milk.  $Rf$  = fat in cream.) Knowing the % of cream and the bacterial content of the cream and the skim-milk, it can be calcd. how many of the bacteria present in the whole milk are obtained in the cream and how many in the skim-milk or what effect centrifuging had on the bacterial content. Of 30 tests the bacterial content of the cream was greater than that of the skim-milk in 12 cases, smaller in 16 and equal in 2. The bacterial content of the cream and skim-milk, as a close inspection of results and consideration of the sources of error shows, is dependent entirely on chance. The reduction period was longer for cream in 20 cases, shorter in 6 cases and the same in 4 cases as that of the whole milk. Differences between whole milk and cream were in most cases not great. The cause of the longer duration of the time of reduction with cream is ascribed to the influence of acids on the decoloration of methylene blue since the cream enriched with air bubbles gave the bacteria more acid to consume than did the whole milk, the self-reduction of the milk and the reducing substances produced by the bacteria not becoming effective till

later. Similarly with skim-milk, the acid-producing air is not excluded by a fat layer so that the time of reduction was longer in 26 cases and the same in but 4. Expts. showed that the relative bacterial content as well as the relative time of reduction of whole milk, cream and skim-milk was not changed by preservation 48 hrs. in sterilized bottles. The following conclusions are drawn: the quality of cream can be judged by means of the reductase test as well as can that of whole milk. This holds good for cream coming directly from the centrifuge as well as that kept 1 to 2 days. The reduction period of skim-milk is at times a little longer than that of whole milk, presumably because of the fact that there is no layer of cream on its surface to prevent access of air. The expts. furnish no support for the assertion that de-creaming by the centrifuge makes the cream richer and the skim-milk poorer in bacteria. No obvious effect of centrifuging on the division of bacteria could be observed. ALBERT R. MERZ.

**New method for the analysis of butter.** PAUL ERCULISSE AND HENRI DACKWEILER. *Ann. chim. anal.* 23, 225-34(1918).—Proposals are made for the modification of the following numbers in the analysis of butter: (1) sapon. or Koettstorfer no., (2) volatile, sol. acids or Reichert-Meissl-Wolny no., (3) insol. volatile acids or Polenske no., (4) fixed fatty acids or Hehner no. A brief outline of the methods proposed and their advantages are given. LOTTIE M. MANROSS.

**Nematode galls as a factor in the marketing and milling of wheat.** D. A. COLEMAN. U. S. Dept. Agr., *Bull.* 734, 16 pp. (1918).—Black gall resulting from the infection of wheat heads by the nematode (*Tylenchus tritici*) is encountered as a new foreign material in marketing wheat. It has a limited distribution, occurring only in Virginia and California. Chem. analysis of the nematode gall wheat shows that the N-free ext., which in the normal wheat berry consists mostly of starch grains, has been greatly reduced. The crude fiber, crude protein, ash and fat have been largely increased. The acidity of the whole wheat berry has been raised 10 times above that of sound wheat. Starch grains are almost completely absent. Whether the nematodes consumed the starch or whether their presence in the plant resulted in physiol. disturbance precluding starch formation was not detd. The lack of starch in the wheat results in a lower flour yield. The presence of nematodes will increase the percentage of lower grade flour. The loaf made from flour containing the ground galls was inferior in color and had a dark gray crumb. The infected grain when used for planting can be cleaned by immersing seed for 10 to 15 min. in H<sub>2</sub>O at a temp. of 135°. The galls can also be floated out in cold H<sub>2</sub>O, as they are lighter than sound wheat kernels, the difference in wt. being made use of in its sepn. J. J. SKINNER.

**Determination of cellulose in wheat.** V. HASENFRATZ. *Compt. rend. soc. biol.* 81, 457-8(1918).—Five ~~g~~ finely ground wheat and 150 cc. HCl (21.3 g. per l.) were boiled under a reflux condenser for 20 mins.; the residue and 100 cc. KOH soln. were boiled under a reflux condenser for 15 mins. The final residue was then washed with boiling H<sub>2</sub>O (to disappearance of alk. reaction), abs. alc. and Et<sub>2</sub>O, dried and weighed. Native (French), Australian and Manitoba wheats were treated in this manner and the alk. soln. used in various detns. contained 10, 25, 50, 75 and 100 g. per l., resp. The proportion of "cellulose" thus detd. decreased progressively as the concn. of the KOH soln. increased. The max. and min. values for French, Australian and Manitoba wheats were 2.48 and 1.52, 2.76 and 1.68, 3.02 and 1.86%, resp. The relations between the min. and max. values for French, Australian and Manitoba wheats were 1:1.63, 1:1.64 and 1:1.62, resp., thus showing remarkable constancy for the different samples. H. raises the question whether this relationship between these min. and max. values is const. regardless of the kind and origin of wheat and whether a different but const. ratio could be found for other cereals, thus giving this relationship a sp. character.

H. S. PAINE.

**The determination of the moisture content of flour.** F. T. SHUTT AND P. J. MOLONEY. *Trans. Roy. Soc. Canada* 11, III, 101-6(1917).—In detg. the moisture content of flour, satisfactory results were obtained by heating at 100° for 5 hrs. in a Freas electrically heated vacuum oven in which a steady vacuum of 29.5 in. was maintained. Portions of samples approx. 2 g. each were weighed to 0.1 mg. into Al dishes 4.5 cm. diam., 2 cm. in depth. Triplicates showed close checks such as 12.66, 12.67 and 12.64%. Lower results were obtained by heating at atm. pressure in a Freas elec. oven at 100° or in a double-jacketed water oven heated by gas. The temp. of the latter was about 98°, and a period of at least 48 hrs. was required to bring to const. wt. It is shown that the difference in results, comparing those obtained from the vacuum oven with those from the air ovens, is not to be accounted for by any oxidation of the flour, as was at first suspected. Samples dried in the vacuum oven at 100° apparently took up moisture after being transferred to the air oven, being heated therein at 100°. Evidently the ovens operating under atm. pressure are inefficient in drying flour samples. The figures from the vacuum oven are obtained more quickly, are more consistent and represent more nearly the absolute moisture content of the flour. H. M. LANCASTER.

**The chemical composition of wheat, rye and corn germs.** H. KALNING. *Z. ges. Getreidew.* 9, 167 (1917); *Biedermanns Zentr.* 47, 114-6(1918).—The carefully cleaned germs contained dry-matter: wheat, 91.17%; rye, 84.49%; corn, 90.65%. The dry matter contained:

|                                                           | Wheat germs.  | Rye germs.   | Corn germs. |
|-----------------------------------------------------------|---------------|--------------|-------------|
| Ash.....                                                  | 5.50%         | 5.54%        | 6.05%       |
| Fat.....                                                  | 12.00         | 11.95        | 24.36       |
| Protein.....                                              | 40.75         | 44.74        | 15.11       |
| Crude fiber.....                                          | 2.50          | 3.94         | 5.76        |
| N-free ext.....                                           | 39.25         | 33.83        | 48.72       |
| Pentosans.....                                            | 11.55         | 7.32         |             |
| Starch (Ewers).....                                       | 13.00 approx. | 6.00 approx. | 24.75       |
| P <sub>2</sub> O <sub>5</sub> .....                       | 2.52          | 3.11         |             |
| % P <sub>2</sub> O <sub>5</sub> H <sub>2</sub> O-sol..... | 65.10         | 56.30        |             |
| Reducing sugar.....                                       | 4.07          | 6.66         |             |
| Sugar after inversion.....                                | 18.56         | 22.62        | 8.00        |
| H <sub>2</sub> O-sol. protein.....                        | 19.76         | 21.55        |             |
| Alc.-sol. protein (60% alc.).....                         |               | 5.55         |             |
| Aq. ext.....                                              | 34.61         | 51.44        |             |

The large starch content of the corn germs is to be attributed to the fact that they cannot be sepd. as well in milling as the others. A number of cleavage products such as allantoin, betaine, choline and lecithin were found in the wheat germs. Comparison of nutritive values according to König's method (nitrogenous matter × 5, fat × 3, carbohydrate × 1) gives rye first place with 293, wheat, 279 and corn 197. Comparative digestibility expts. by Honcamp using sheep and swine gave high digestion coefficients which are given in a table. It is concluded that the most important food elements are accumulated in germs in especially high amts.

ALBERT R. MERZ.

**A preliminary study of the bleaching of oats with sulfur dioxide.** G. H. BASTON U. S. Dept. Agr., *Bull.* 725, 11 pp.(1918).—It is shown that it is possible to bleach weather-stained, discolored and damaged oats, giving them the appearance of natural oats of good quality. The viability of oats is greatly reduced by S bleaching and the bleached oats are not safe to use for seed.

J. J. SKINNER.

**Banana flour and other flours from tropical starchy products with notes on banana cultivation.** B. J. EARRON. *Agr. Bull. Fed. Malay States* 6, 430-6(1918).—Com-

parison of analysis of banana flour with flours of cereals as well as a discussion of its nutritive value, its prepn. and use. H. A. LEPPER.

**Physical chemistry of bread making.** E. J. COHEN AND L. J. HENDERSON. *Science* 48, 501-5(1918).—To get good dough the fermentation and acidity must be controlled. This fermentation is decreased by addition of salt or by using less yeast, but is increased by its own activity, which increases the acidity of the dough and makes it rise more rapidly. The acidity of the dough is the most important variable factor. Acidity may be increased by adding more acid or prolonging the process of fermentation. Bread must be baked at the right time so that right amt. of  $\text{CO}_2$  may be retained. Wheat flour dough is more tenacious and elastic than flours from other grains, the latter do not retain the gas. Presence of substitutes makes yeast less active and dough less acid. Serum proteins may be added as substitute for gluten of wheat. Rope occurs often in summer and in low acidity. Proper acidity may be shown by development of full red color when methyl red is put on slice of bread.

LOTTIE M. MANROSS.

**Control of rope in bread.** E. J. COHN, S. B. WOLBACH, L. J. HENDERSON AND P. H. CATHCART. *J. Gen. Physiology* 1, 221-30(1918).—Rope is a condition of bacterial decompn. of bread which leads to a peculiar slimy or ropy consistency of portions of the interior of the loaf, produces an odor resembling ensilage, and renders the loaf unacceptable. *B. mesentericus* was identified from a ropy loaf and inoculation with it produced ropiness. The development of rope from this bacillus depends upon the existence of a H-ion concn. in bread sensibly less than  $10^{-5}$  N. This condition is likely to exist in war bread or other breads containing other than wheat flour. The addition of acids will prevent ropiness. The growth of yeast tends to produce a very acid reaction and prevents the development of *B. mesentericus*. Methyl red, when colored red, indicates the reaction to be acid enough to prevent ropiness. H. A. LEPPER.

**The utilization of some nuts as food.** F. A. CAJORI. Yale Univ. *J. Home Econ.* 10, 304-11(1918).—Metabolism expts. on the utilization of the N in protein-rich nuts, and on the utilization of the carbohydrates and proteins of the chestnut, litchi nut and coconut. Various nuts were added to a uniform diet given to men and to dogs. The dietary intake was made sufficient for the calorific needs of the subjects. The "coeff. of digestibility" of the N in the various diets was as follows: almond 84-89, almond paste 88-89, peanut 81-85, peanut paste 90-92, pecan 83-84, pecan paste 81-83, pine 89, English walnut 83, coconut 87-89, litchi 81-82, brazil 88. A basal diet gave 84-90. L. D. ELLIOTT.

**Calcium oxalate in the dasheen.** O. F. BLACK. *Am. J. Botany* 5, 447-51(1918).—The experimental evidence submitted shows that  $\text{CaC}_2\text{O}_4$  crystals cause the acrid taste of the dasheen by the mechanical irritation of the mucous membrane of the mouth. The dasheen synthesizes  $\text{CaC}_2\text{O}_4$  in the form of "raphides." Such crystals when mixed with paraffin and taken in the mouth produce a similar sensation. The acrid flavor of dasheen can readily be removed by proper methods of cooking. J. J. SKINNER.

**The preservation of potatoes, especially by means of "megasan."** L. HILTNER. *Praktische Blätter für Pflanzenbau und Pflanzenschutz* 15, 66-0(1917); *Biedermanns Zentr.* 47, 125-8(1918).—"Megasan" is a manufd. prepn. consisting mainly of Na boroformate which slowly evolves formic acid and is claimed to destroy putrefactive fungi and prevent decay. Megasan II contains talc, megasan III contains washed kieselguhr and megasan K is a solid soln. of Na boroformate in ignited kieselguhr. Comparative expts. of the effect of megasan III and of S,  $\text{CaO}$ ,  $\text{CaCO}_3$ , gypsum, chaff, saw-dust and peat mull on the preservation of potatoes kept over winter in wooden boxes in a cellar show that only saw-dust and peat mull brought about a pronounced

decrease of decay. Best results were obtained from the latter. Treatment with megasan III actually increased the % of decayed tubers.  $\text{CaO}$ ,  $\text{CaCO}_3$  and gypsum caused very high losses in wt. which is apparently not due altogether to loss of  $\text{H}_2\text{O}$ . Other investigators have had good results with megasan K. This has the power of absorbing  $\text{H}_2\text{O}$  and drying the air in the heap and H. questions the benefits as derived from the formic acid. Further work is in progress on the detn. of the cause of the losses in wt. and with the use of megasan K.

ALBERT R. MERZ.

Teas of commerce. INES PIEROTTI. Univ. La Plata. *Anales soc. quim. Argentina* 6, 329-43(1918).—P. reports analyses of a large no. of teas from various sources. The min. and max. values (as %) for various detns. were as follows: loss of wt. at  $100^\circ$ , 6.699, 9.974; ash, 5.421, 6.091; aq. ext., 24.046, 38.993; total N, 3.501, 4.399; matter sol. in  $\text{CCl}_4$ , 0.502, 2.546; matter sol. in  $\text{CHCl}_3$ , 1.110, 5.881; matter sol. in  $\text{EtOH}$ , 3.314, 15.186; theine, 2.071, 3.646; dextrin and gums, 4.044, 6.967; protein, 22.568, 27.493; cellulose, 11.944, 14.933; tannin, 9.092, 14.553. Dextrins and gums were detd. by pptn. with alc., theine by the Grandval and Lajoux method, and tannin by the method of F. Jean. Cellulose was detd. in the residue remaining after treatment with  $\text{CCl}_4$ ,  $\text{CHCl}_3$  and  $\text{EtOH}$ .

H. S. PAINE.

Criticism of the volumetric ferric chloride method proposed by Sabatini for determining the purity of maté (*Ilex paraguensis* St. Hil.). LUIS GUGLIALMELLI AND CARLOS GUERRERO ESTRELLA. *Anales soc. quim. Argentina* 6, 136-50(1918).—G. and E. have made a critical study of Sabatini's method (*C. A.* 12, 1218) which, according to the latter, is based on the reducing action of caffeine on  $\text{Fe}^{++}$  salts. The procedure recommended by S. was followed and samples of *Ilex paraguensis* from various localities (including portions of Brazil and Paraguay) were tested as were also various adulterants such as *Ilex dumosa* Reiss, *Ilex affinis* Gaertner, etc. S.'s procedure provides for a variation in which the concn. of the  $\text{Fe}_2\text{Cl}_6$  soln. used for titration, the wt. of material employed and the vol. of hot  $\text{H}_2\text{O}$  used for extn. are increased 10 fold. G. and E. tested both the original method and the variation and the aq. exts. obtained in both cases were titrated (1) while hot and (2) after cooling to room temp. Discordant results were obtained not only with respect to the original method and the variation, but also as regards hot and cold titration and *Ilex paraguensis* as compared with its adulterants. The discrepancy in results was found to be due in part to varying degree of hydrolysis of  $\text{Fe}_2\text{Cl}_6$  at different dilns. and temps. in the aq. soln., thus causing a variation in the vol. of added  $\text{Fe}_2\text{Cl}_6$  for which the reaction with  $\text{KSCN}$  first became perceptible. Expts. with aq. solns. of caffeine showed that this compd. has no reducing action on  $\text{Fe}_2\text{Cl}_6$ . The discordant results obtained with infusions of pure maté and its adulterants are attributed on the whole to hydrolysis of  $\text{Fe}_2\text{Cl}_6$  and reaction of the latter with polyphenols present in the plant infusions examd. The method proposed by Sabatini is regarded as having little value, although it might possibly, after some modification, be used for evaluating the polyphenols present in the plant exts.

H. S. PAINE.

Witgatboom. A substitute for chicory. J. McCRAE AND A. KLOOT. *Analyst* 43, 373-4(1918).—Roots of "witgatboom" (white-hole trees) are used as substitutes for chicory in South Africa. *Boscia transvaalensis*, Pest., *B. rehmanie*, Molrua *pedunculata*, Sim., and *Capparis albivernca* are the four most used. Analyses of the first and third named as well as botanical descriptions are given.

H. A. LEPPER.

Chemistry of certain mushrooms ("täublinge"). EMIL HERRMANN. *Pharm. Zentr.* 59, 73-5(1918); *Chem. Zentr.* 1918, I, 925.—A short compilation of present knowledge of the content in "täublinge" of acids, bases, carbohydrates, enzymes and coloring materials. [The term "täublinge" is applied to mushrooms derived from several species of *Lactarius* and *Russula*.—ABSTR.]

C. O. EWING.

**Odors of fungi.** E. HERRMANN. *Pharm. Zentr.* 59, 1-4, 7-10, 19-21(1918); *Chem. Zentr.* 1918, I, 840.—A comprehensive compilation of the odorous characteristics of some of the higher fungi, including a discussion of the relation between odor and edibility, and of the value of the odor as a means of identification. Cf. C. A. 10, 1767. C. O. EWING.

**The fruits of the moriche palm.** ANON. *Bull. Dept. Agr. Trinidad and Tolo* 17, Pt. 2, 104(1918).—A description of the palm. An analysis of the air-dry shell and kernels by A. E. Collens is reported. The dried kernels of the fruits are extremely hard and horny, resembling white ivory and they appear to be suitable for making artificial buttons, though subject to weevil attacks in tropical climates.

R. B. DEEMER.

**The composition and digestibility of reeds (*Arundo phragmites*) and rushes (*Scirpus maritimus*).** F. HONCAMP AND E. BLANCK. *Versuchsstationen* 90, 113-22 (1917); *Biedermanns Zentr.* 47, 225-6(1918).—These have been used in Germany as cattle food because of scarcity of feed. Analyses are given and the digestion-coeffs. secured by feeding to 3-yr. old sheep are reported.

ALBERT R. MERZ.

**Feeding experiments with dairy cows in Denmark.** A. V. LUND. Copenhagen. *Mitt. deutsch. Milchwirtschaft. Vereins.* 34, 172(1917); *Biedermanns Zentr.* 47, 230-2 (1918).—The results of comparative feeding expts. with beets and turnips are reported. Expts. with "cacao cake" indicate that it should be considered rather as a poison than a feed.

ALBERT R. MERZ.

**The losses involved in the preparation of dry hay and the production of silage.** J. AHR AND CHR. MAYR. Weihenstephan. *Fühlings landw. Presse* 66, 185-211 (1917); *Biedermanns Zentr.* 47, 69-78(1918).—The losses of dry matter occurring under the various conditions of the prepn. of hay on meadows were studied. The amt. of grass obtained from each exptl. plot was weighed immediately after mowing and an av. sample taken therefrom and immediately weighed. The content of dry matter was detd. in this sample after drying as rapidly as possible in an oven. After carefully drying the grass by one of the local methods of making hay the hay on each plot was weighed before harvesting and the content of dry matter again detd. in an av. sample. The amts. of dry matter in the fresh grass and the hay were calcd. from the data thus obtained and their difference represents the loss of dry matter. The hay was prepd. either by drying the grass on the ground or by hanging it up in "so-called hay-huts" which insured the crop as to quantity and quality. The 133 sep. expts. comprize 7 series. Observations on meadow fertilization expts. were carried on simultaneously with the detn. of losses. Series I, Pfaffanger, 1915: The effect of fertilization with  $P_2O_5$  and  $K_2O$  was shown by slight increases in the amt. of clover. N in addition to  $P_2O_5$  and  $K_2O$  increased the yields in the following order:  $NaNO_3$ ,  $(NH_4)_2SO_4$ ,  $CaCN_2$ . With complete fertilization, drying on the ground caused losses of dry matter as follows: with  $NaNO_3$ , 3.7%;  $(NH_4)_2SO_4$ , 4.6%;  $CaCN_2$ , 10%. Without N the loss was 11.9% and with no fertilizer at all the loss was 17%. The very great differences were explicable by the different compn. of the herbage. Series II, Muhlanger, 1915: The clover herbage was very slightly increased by unbalanced fertilization with  $P_2O_5$ . Unfertilized plots were almost devoid of clover.  $K_2O$ - $P_2O_5$  fertilization brought about the greatest increase in yield as well as an increase in the papilionaceous plants. N salts in addition to the  $P_2O_5$ - $K_2O$  somewhat lessened the crop yield and promoted the growth of the grasses with the suppression of clovers. The loss of dry matter was greatest with the N-free fertilization, less with simultaneous N fertilization and least with extensive suppression of clover, on plots having unbalanced fertilization with  $K_2O$  or  $P_2O_5$ . Series III, Schelter, 1915:  $K_2O$ - $P_2O_5$  fertilization brought about an increase of yield with simultaneous increase in the amount of clover. Differences in losses on drying were

very small. Series IV, Pfaffanger, 2nd cutting, 1915: There was complete absence of effect due to fertilization; also no differences in the relative amts. of the herbage. Series V, 2nd cutting, 1915, on plots of Series II: Unbalanced fertilization with  $P_2O_5$  increased the yield 800 kg. per ha.;  $K_2O$ , 500 kg. per ha. and  $K_2O-P_2O_5$ , 1600 kg. per ha. Clovers were increased in amount. N fertilization was unfavorable, least so cyanamide. Losses of dry matter in "hut-drying" and with full fertilization with  $(NH_4)_2SO_4$  and cyanamide were small. With "ground drying" the unfertilized plots showed least losses. Series VI, Pfaffanger, 2nd cutting, 1916: The previous year's fertilization with  $P_2O_5$  and  $K_2O$  showed good after-effects while the 3 N fertilizers failed to show any crop increasing effect. There were no significant differences in the composition of the herbage. "Detns. of losses of dry matter confirmed the results of Series V." Series VII, Muhllanger, 2nd cut, 1916: The previous year's fertilization with  $P_2O_5$  showed no noticeable after effect.  $K_2O$  produced an increased yield of 300 kg. per ha.  $K_2O-P_2O_5$  increased the 2nd crop by 400 kg. and the total yield of the year by 1550 kg. per ha. "Untergräser" and clovers predominated.  $NaNO_3$  increased the first cutting more than cyanamide. The differences in loss of dry matter for ground drying varied between 4.3 and 13.5% with the different kinds of fertilizer. Losses in drying are in general attributable to respiration and oxidation processes. Losses by respiration are less after wilting by exposure to the sun's rays, air-drying, heat and aeration. The assumption that the more digestible parts of the organic matter of highest value are concerned in the losses is justified. After harvesting, fermentation processes take place in storage according to the moisture content, ripeness, and composition of the herbage. Losses by fermentation in making silage can be limited to 10%.

ALBERT R. MERZ.

**Feed substitutes.** BALLAND. *Compt. rend. acad. agr. France* 4, 969-71(1918).—Analyses are reported of distillery malt (1 sample), beet flour (1), cacao bran (1), peanut meal cake (6), and carambola meal cake (2). The av. analysis of carob pods is also given. These contain 30 to 40% sugar and almost as much starch. Carobs are food for both man and beast.

ALBERT R. METZ.

**Utilization experiments with wooly seed meal, rumen mixture feed, horse chestnut refuse, bone feed meal, albumin economizing feed, Badersche meat meal, detanned leather scraps and horn meal.** A. MORGEN, C. BEGER, H. WAGNER, H. v. BREEREN, ELISA OHLMER AND J. MICHALOWSKI. *Landw. Verssta.* 89, 269(1917); *Biedermanns Zentr.* 47, 132-6(1918); cf. *C. A.* 11, 1702.—The expts. were conducted with sheep, using meadow hay as the main constituent of their food to which the above named feeds were added. Wooly seed meal (1) differs essentially from cotton seed meal only in a higher content of crude fiber. It is a very good source of protein for feeds. The animals must be gradually accustomed to it. Rumen feed (2) consists chiefly of the dried contents of rumens with some molasses and other additions. The water content should not be higher than 20% or it will deteriorate. It may be best compared with wheat bran. Horse chestnut refuse (3) is obtained in the manuf. of starch from horse chestnuts. Its value lies almost entirely in its N-free ext., as the protein is indigestible, and it contains only small amts. of fat and crude fiber. Bone feed meal (4) can be used only in small amts. because of its high content of mineral matter. Albumin economizing feed (5) consists mainly of gelatin with some bits of bone and a little horn. Badersche meat meal (6) is apparently made from the scraps which are obtained prior to the conversion of hide into leather. The crude protein consists mainly of gelatin or collagen. Detanned leather scraps (7) are said to be produced by a special process from the scraps of chrome-tanned leather reconverting them into the former raw hide. In external characteristics it resembles the Badersche meat meal but chemically more nearly the albumin economizing feed. Only traces of Cr were found. The horn meal (8)

gave poor results as a feed. Only 15% of its N was digested. Analyses of these feeds were as follows:

|                       | 1.    | 2.    | 3.    | 4.   | 5.    | 6.    | 7.    | 8.   |
|-----------------------|-------|-------|-------|------|-------|-------|-------|------|
| H <sub>2</sub> O..... | 10.62 | 19.79 | 10.96 | 3.00 | 12.12 | 14.91 | 10.60 | 4.2  |
| Crude protein.....    | 40.85 | 14.50 | 5.81  | 20.7 | 77.80 | 57.80 | 70.78 | 94.6 |

| Org. matter.....      | 81.41 | 70.39 | 87.60 | 33.2 |       |       |       |      |

Coeffs. of digestibility are given for the different food elements. ALBERT R. MERZ.

**Coconut meal vs. cottonseed meal for dairy cows.** P. V. EWING AND E. R. SPENCE. Texas Agr. Expt. Sta., *Bull.* 225, 9 pp.(1918).—For economy of production of butter fat there was not much difference between feeding cottonseed meal, coconut meal and a mixt. of the two. Coconut meal feeding produced on the av. 0.2% more of butter fat. It is not as palatable as cottonseed meal and often becomes rancid.

J. J. SKINNER.

The foodstuff content of various brewery yeasts and of mineral yeast (MEYER) 16.

**Fats in powdered form for use in foods.** F. C. ATKINSON. U. S. 1,286,903, Dec. 10. A fat is melted, mixed with an active constituent of baking powder such as KH tartrate and the mixt., while hot, is sprayed into a chamber in which the temp. is below the congealing point of the fat. The powdered product may then be mixed with NaHCO<sub>3</sub> to form a baking powder.

**Baking powder.** F. C. ATKINSON. U. S. 1,286,904, Dec. 10. Hydrogenated corn oil is used for coating NaHCO<sub>3</sub> or other constituents of baking powder according to the method of U. S. pat 1,286,903 (*supra*).

**Deodorizing cream.** J. PRISKEY. U. S. 1,286,404, Dec. 3. Compressed air is forced into the cream through a body of hollow porous material immersed in it.

**Flour and meal.** J. SLEEMAN. Brit. 119,923, Oct. 26, 1917. In a process of preparing flour and meal from fruits, roots, vegetables, berries, and the like, the materials, after washing if necessary, are sliced or pulped, the liquid portion being expressed if necessary, and the slices further dried until the moisture is reduced to between 5 and 12%. The dried material is then ground and sifted. The coarser particles are used as cattle food, while the finer flour may be mixed with flour or malt, or with wheaten flour or the like. The expressed liquid may be fermented and converted into spirit, for potable or power purposes, or may be used for the extn. of sugar or starch. Cf. 21,038, 1892, 2,981, 1903, 26,794, 1905, 1,074, 1909, 16,651, 1909, 17,723, 1913 (C. A. 9, 339), and 8,371, 1915.

#### 14. WATER, SEWAGE AND SANITATION.

EDWARD BARTOW AND W. F. MONFORT.

**Graphic representation of the chemical composition of natural waters.** ENRIQUE HERRERO DUCLOUX. *Anales soc. quim. Argentina* 6, 102-7(1918).—The system proposed is based on the classification of the analytical data into 2 groups, i. e., (1) those which refer to the saline compn. and (2) those which serve as an index of potability. The data of group 1 are composed of detns. of 6 electropositive and 6 electronegative radicals (calcd. as ions), viz.: SiO<sub>3</sub>, SO<sub>4</sub>, CO<sub>3</sub> (also CO<sub>3</sub>H and CO<sub>3</sub>), Cl, NO<sub>3</sub>, SH, Fe,

Al, Ca, Mg, K, Na. A hexagon is drawn with sides 20 mm. in length. Two ions (one electropositive and one electronegative) are arbitrarily assigned to each point of the hexagon in a const. order, viz.: K, NO<sub>3</sub>, Al, S (SH); Na, Cl; Ca, SO<sub>4</sub>; Mg, CO<sub>3</sub> (CO<sub>2</sub>, CO<sub>2</sub>H); Fe, SiO<sub>2</sub>. The radii (of the circle circumscribing the hexagon) which pass through the points of the hexagon are extended and the magnitudes of the contents of the 2 ions in question are represented linearly and simultaneously on the extension of each corresponding radius on a scale where 0.01 g. = 1 mm. The points on the extensions of the radii which are thus detd. by the electronegative ions are connected by straight (red lines) and the points detd. by the electropositive ions are likewise connected (by blue lines), thus producing 2 distorted hexagons enclosing the original hexagon; the distortions of the 2 hexagons are thus graphically characteristic of the saline compn. of the H<sub>2</sub>O. The data (color, odor, dissolved organic matter, nitrites, NH<sub>3</sub>, etc.) of group 2 are regarded as indicating that the H<sub>2</sub>O is (1) pure, (2) suspected or (3) non-potable; these conditions are, respectively, represented by (1) leaving the central hexagon white, (2) ruling this hexagon in one direction, and (3) by ruling it crosswise. In making the above graphical representation the values for Al and Fe are multiplied by 10 on account of their small magnitude. CO<sub>2</sub>H is represented on the extended radius corresponding to CO<sub>3</sub> by measuring outward from the point of the hexagon on the same scale used above, the magnitude of CO<sub>2</sub>H being, however, represented linearly on this radius rather than by the distortion of the hexagon as in the case of CO<sub>3</sub>. CO<sub>2</sub> is represented linearly by a line drawn at an angle from the extremity of the CO<sub>3</sub> radius. The lines representing CO<sub>3</sub>, CO<sub>2</sub>H and CO<sub>2</sub> converge, therefore, at one point, i. e., the extremity of the CO<sub>3</sub> radius. The saline residue at 180° is indicated in the center of the central hexagon and the temp. of the H<sub>2</sub>O is shown below the source of the latter above the hexagon. The electronegative ions of H<sub>2</sub>BO<sub>3</sub>, H<sub>2</sub>PO<sub>4</sub>, HF and H<sub>2</sub>AsO<sub>4</sub> and the ions Mn, Li, etc., are shown, if desired, at the side of their related ions (periodic classification), their relative proportions being indicated by exclamation marks. The above graphic representation gives a practically complete, condensed picture of the data of the usual H<sub>2</sub>O analysis.

H. S. PAINE.

Ilkeston and Heanor water-softening plant and the utilization of refuse lime. ALFRED E. SMITH. *Surveyor* 53, 238-40(1918).—A hard water is softened by the use of CaO. The sludge is dried and sold for use in hardening waters to reduce plumbosolvency; to manufacturers of toilet, face, tooth, and polishing powders, of aerated waters, and to other smaller users.

W. D. C.

The hot mineral springs of Rio Hondo. HÉRCULES CORTI. *Anales soc. quim. Argentina* 6, 215-29(1918).—C. reports the results of physical and chem. examn. of the H<sub>2</sub>O from a no. of hot springs in Rio Hondo (Argentina) in a locality called "Las Termas." Chem. examn. included the following detns.: mineral substance in suspension, reaction (hot and cold) to litmus and phenolphthalein, total and true alkalinity, organic matter, residue at 100-5° and at redness, H<sub>2</sub>SO<sub>4</sub> residue, hardness (total, permanent and temporary), SiO<sub>2</sub>, SO<sub>3</sub>, CO<sub>2</sub>, NaCl, N<sub>2</sub>O<sub>5</sub>, N<sub>2</sub>O<sub>3</sub>, H<sub>2</sub>S, Al<sub>2</sub>O<sub>3</sub>, Fe<sub>2</sub>O<sub>3</sub>, CaO, MgO, NH<sub>4</sub>, O and N. Nitrites and NH<sub>3</sub> were only detected in traces if at all. The H<sub>2</sub>O from a no. of the springs contained traces of As, Mn, F, Br, I, P and Ti. Abundant evolution of gas composed of 2 parts N, 1 part O and traces of CO<sub>2</sub> was noted in some of the springs. Samples of H<sub>2</sub>O from a no. of the springs showed varying degrees of radioactivity. The waters of these springs are to be classified as thermal, slightly mineralized and ferruginous (cf. Ducloux's classification of Argentine mineral waters). C. discusses the various characteristics of mineral waters to which therapeutic efficacy may be ascribed and points out the many instances of therapeutic efficiency which still cannot be explained on the basis of these characteristics.

H. S. PAINE.

**Study of the waters of the Atlantic ocean along the Argentina coast.** HÉRCULES CORTI AND HECTOR H. ALVAREZ. *Anales soc. quim. Argentina* 6, 108-20(1918).—C. and A. report analyses of samples of  $H_2O$  of the Atlantic Ocean taken at various points along the Argentina coast, this being the beginning of a systematic oceanographic investigation modeled somewhat after that conducted by the Oceanographic Institute of Monaco. The analyses include the usual detns. of a  $H_2O$  analysis; the examn. of these waters has also been considered from the standpoint of their efficacy in thalassotherapy, samples having been taken at various watering places on the Argentina coast. No general deductions have so far been indicated and reference must be made to the original for data.

H. S. PAINE.

**Temporary and semi-permanent water supplies.** V. P. SMITH. *Professional Papers R. Eng., 4th Series*, No. 10(1918); *Water Water Eng.* 20, 269-71.—A discussion of military practice in construction and operation of camp and field supplies. "Possibly the expert engineer will find little new to him; but for the purpose of military engineers in the field or young engineers in charge of a large staff of workers in an unsettled country, the details supplied cannot fail to be of great assistance." M. C. PERRY.

**Distilled water and its substitutes.** P. CARLES. *Rev. prod. chim.* 21, 314; *Repert. pharm.* 29, 313-5; *Water and Water Eng.* 20, 289.—Owing to coal shortage distd. water is difficult to obtain, and must be replaced in many uses by water decalcified by some other methods. For industrial purposes lime may be eliminated by simple dosage with oxalic acid, proportioned to the degree of hardness as detd. by chemical analysis; where the hardness is unknown, the successive approximation test must be resorted to until the  $H_2O$  is no longer whitened by the acid. C. also warns against the growing use of leaden condenser pipes in the distn. of potable liquids. M. C. PERRY.

**The elimination of spurious presumptive tests for *Bacillus coli* in water by the use of gentian violet.** IVAN C. HALL AND LILLIAN JORDAN ELLEFSON. *Univ. Cal. J. Bact.* 3, 329-54(1918).—An investigation of the inhibitory action of gentian violet on gram-positive bacteria.

JOHN T. MYERS.

**The control of small sewage works.** JAMES H. EDMONDSON. *Surveyor* 54, 183 (1918).—The following tests are recommended: *Oxygen absorbed*: In a stoppered bottle place 100 cc. sample and 10 cc.  $KMnO_4$  soln. (0.4 g.  $KMnO_4$  and 100 cc.  $H_2SO_4$  in 1 liter). Note the time required for the color to disappear. *Nitrates*: Mix 5 cc. effluent and 2.5 cc. 1% brucine soln. in a Nessler tube and pour down the side of the tube 2.5 cc.  $H_2SO_4$ . Note the formation of a pink zone gradually changing to amber. *Turbidity*: Measure depth in a Nessler tube required to obscure black lines ruled on white paper under the tube. *Odor and stability*: Good effluents should have no offensive odor in a stoppered bottle 4-6 days at 80° F. Color from 6 drops of methylene blue soln. should persist 4 days in a stoppered bottle at 80° F.

W. D. C.

**Two sludge problems.** ARTHUR J. MARTIN. *Surveyor* 54, 195-6(1918).—Sewage treated by the activated-sludge process requires from 20 to 70 times the amount of air necessary to furnish the O needed to combine with the organic matter. This excess is required to perform the mixing and because the air passes rapidly through the sewage. M. proposes the use of long horizontal cylindrical tanks, the contents of which are maintained in a state of rapid rotation, combined with a slow longitudinal flow. The rotation may be produced by jets of sewage or air. For removal of a considerable part of the water or sludge it is suggested that the sludge be allowed to settle in tall shafts, where its own weight would consolidate the material and force it out through doors at the base of the shaft. With activated sludge it might be necessary to blow air through the shaft to prevent de-aeration.

W. D. C.

**Sewage treatment at Manchester: Activated-sludge research work.** ANON. *Surveyor* 53, 4-5(1918).—The operation of the works for the fiscal year 1917 was satis-

factory, although reduction of the load on the filtration areas was necessary in order to secure effective operation with the effluents from chemical works. Experimental runs indicated that the activated-sludge treatment is successful in the presence of wastes from manuf. of sulfate of ammonia, products from benzene and aniline, and from a dye works, but more time is required for aeration.

## 15. SOILS, FERTILIZERS AND AGRICULTURAL POISONS.

---

J. J. SKINNER.

**Relationship between the unfree water and the heat of wetting of soils and its significance.** G. J. BOUYOUCOS. Michigan Exp. Sta., *Bull.* 42, 23 pp.(1918).—Thirty-two soil samples, 1 of lampblack, 1 of silica, and 1 of quartz sand were studied by means of a special calorimeter, or thermos jar, which detd. the heat of wetting of the material when treated with  $H_2O$ . The heat of wetting was found to bear a close relationship to the unfree  $H_2O$ , and in particular to that portion of the unfree  $H_2O$  which does not freeze even at  $-78^\circ$  and which has been termed combined  $H_2O$ . It was found that both of these factors tended to vary in the same parallel order in almost all of the soils. In the examn. of 7 soils, quartz sand, kaolin, silica, lampblack,  $Ca_3(PO_4)_2$ ,  $CaO$ , and  $BaSO_4$ , as affected by ligroin alone, ligroin and  $H_2O$ , and  $H_2O$  alone, it was found that with the exception of silica, lampblack, and  $Ca_3(PO_4)_2$  the heat of wetting of the solid materials in ligroin was either entirely absent or very small, while when  $H_2O$  was added to them while still immersed in the ligroin heat was evolved in all of the agr. soils except peat, and in all artificial materials except quartz sand, lampblack, and  $BaSO_4$ , the rapidity and magnitude being almost the same as in  $H_2O$  alone. The article contains full references to previous work leading up to this investigation and gives a full discussion of the theories advanced to explain the results reported.

R. B. DEEMER.

**Soil solution as an index of the biological changes in the soil.** J. F. MORGAN. Michigan Agr. Exp. Sta., *Bull.* 39, 24 pp.(1918).—The van Suchtelen and Itano

method for obtaining the soil soln. was used to obtain solns. which could be studied to observe the effect thereon of various fertilizers. Dried blood, tankage, cottonseed meal,  $\text{NaNO}_3$ ,  $(\text{NH}_4)_2\text{SO}_4$ , were used and the solns. were tested for sp. gr., sp. cond., f.-p. depression, total solids, reaction, and for N as  $\text{NH}_3$ , as nitrite and as nitrate. It was found that the solns. from the treated soils were more concd. than their respective controls, and the treated soils contain more microorganisms. M. concludes that the soil soln. thus obtained furnishes a suitable means of studying microbial changes in the soil, and since the soil soln. contains the plant ingredients in a form utilizable by the plant it furnishes a better means of detg. in what the soil is deficient. R. B. DEEMER.

**Investigation of peat bogs.** A. ANREP. Canada Dept. of Mines, *Summary Rept.* 1917, 56-8.—This rept. is a statement of the result of surveys of several of the larger bogs of Canada. These bogs cover approx. 7,115 acres. Several of them are recommended as being suitable for the manuf. of peat litter on a commercial scale. The more valuable ones are formed of sphagnum mosses and are practically free from humus. R. L. SIBLEY.

**The partial sterilization of soils and the influence of soil protozoa on their fertility.** GEORGES TRUFFAUT. *Compt. rend. acad. agr. France* 4, 1049-57(1918).—See C. A. 13, 153. ALBERT R. MERZ.

**The partial sterilization of the soil.** *Compt. rend. acad. agr. France* 4, 1030-8 (1918).—A discussion of the preceding paper by members of the Academy.

ALBERT R. MERZ.

**The occurrence of *Azotobacter* in cranberry soils.** SELMAN A. WAKSMAN. *Science* 48, 653-4(1918).—The portion of a Savannah bottom cranberry bog which had been limed gave almost double the crop of the unlimed plot. The unlimed soil had H-ion concn. of  $P_H$  5.4 to 5.6, while for the limed soil  $P_H$  was 6.2-6.4. Cultures from limed soil in N-free mannitol solns. showed *Azotobacter* cells and *Actinomyces* filaments; those from the unlimed soil showed neither. "This will confirm the results of Gainey (C. A. 12, 2221) and Christensen (C. A. 12, 1807) that hydrogen-ion concn. of the soln. =  $P_H$  6.0 is the limiting reaction for the activities of *Azotobacter* in the soil."

ALBERT R. MERZ.

**Theories concerning soils as media for plant growth.** C. B. LIPMAN. Univ. Calif. *School Sci. and Math.* 18, 686-791(1918).—An address in which is given a survey of the important theories in the history of soil studies. J. J. SKINNER.

**Utilization of phosphate deposits of Australia.** J. W. PATERSON. Commonwealth of Australia, Advisory Council of Sci. and Ind., *Bull.* 7, 96-107(1918).—A review of the research bearing upon the utilization of phosphates in plant production and a special plea for a systematic investigation of the value of local deposits to encourage, if advisable, their use in the manuf. of superphosphate. R. B. DEEMER.

**Condition of fertilizer potash residues in Hagerstown silt loam soil.** WILLIAM FREAR AND E. S. ERB. Penn. Agr. Expt. Sta. *J. Agr. Research* 15, 59-83(1918).—Comparative studies were made of two plats of Hagerstown silty loam, of which one had received 18 biennial dressings of 200 lbs. of KCl, while the other had received no KCl. Analyses were made of total  $\text{K}_2\text{O}$ , and  $\text{K}_2\text{O}$  sol. in HCl (d. 1.115), 0.2 N HCl, distd.  $\text{H}_2\text{O}$ ,  $\text{CO}_2$  soln., and N/3  $\text{NH}_4\text{Cl}$ . The total  $\text{K}_2\text{O}$  of the two soils was about the same, that of the untreated being slightly higher, 3.821% to 3.543% in the treated soil, while percentages of the total  $\text{K}_2\text{O}$  dissolved by the various solvents were as follows, the first number being for the untreated plot: strong HCl 9.65, 11.49; 0.2 N HCl 0.374, 0.850; distd.  $\text{H}_2\text{O}$ , 0.084-0.118, 0.138-0.226;  $\text{CO}_2$  soln., 0.199, 0.395; and N/3  $\text{NH}_4\text{Cl}$ , 0.246, 0.528. A second extn. with N/3  $\text{NH}_4\text{Cl}$  gave 0.052, 0.059. Samples of each soil were sepd. into clay and non-clay portions and each was treated with

$N/3$   $NH_4Cl$ ; the percentages of total  $K_2O$  removed from each were: Clay 0.761, non-clay 0.102, 0.32. Analyses from previous work upon the same plots by other investigators, showing the  $K_2O$  content of oats, corn, wheat and hay grown upon these or similar plots, are included, and show that in every case more  $K_2O$  is removed from the treated soil, the increase over the amt. removed from the corresponding untreated soil ranging from 15% in the case of corn to 75% in the case of hay. The total  $K_2O$  removed by these crops, however, would account for only one-fourth of the total amt. applied, leaving a residue of 1300 lbs. per acre applied during the 36-yr. period yet unaccounted for. The soils are naturally rich in  $K_2O$  and the yield of the above mentioned crops was no greater upon the treated than upon the untreated plots. On the basis of the quantities removed annually by the plants, the amt. dissolved by distd.  $H_2O$  is sufficient to last the plants 4 yrs., while the corresponding numbers for the other solvents are: carbonated  $H_2O$ , 7 yrs.;  $NH_4Cl$ , 9 yrs.; and 0.20  $N$   $HCl$ , 13 yrs.

R. N. HARGER.

**Effect of hydrocyanic acid gas under vacuum conditions on subterranean larvae.** E. R. SASSER AND H. L. SANFORD. Federal Horticultural Board. *J. Agr. Research* 15, 133-37(1918).—To test the efficiency of fumigation with  $HCN$  upon plants the roots of which have been balled in wet earth, 3 species of subterranean larvae were buried from 1 to 3 inches deep in dry, moist and soaked earth and the soil was fumigated with  $HCN$  under varying conditions of pressure and time. The fumigation chamber was first partly evacuated and the  $HCN$  then allowed to enter. Very good results were obtained with the dry and moist soils using 0.5-1.5 ounces of  $HCN$  per 100 cu. ft. with an initial vacuum of 27 in. for 15 min. and then atm. pressure for 1.5 hrs., but with the soaked soil even 3 oz. of  $HCN$  per 100 cu. ft. under pressures ranging from 26 in. vacuum to 10 lbs. pressures failed to kill 100%.

## 16. FERMENTED AND DISTILLED LIQUORS.

ROBERT WAHL.

**Chinese wines.** Y. P. SUN. *Far Eastern Rev.* 14, 365-6(1918).—S. reports upon the use and manuf. of spirits by the Chinese, indicating 3 general types. Two of these are fermented liquors containing about 10% alc., the other is a distd. liquor averaging 45% in alc. content. All are mistakenly termed "wines." The author describes crude forms of distg. app. still in use. Rice and "kao-liang" are the grains commonly used.

WM. H. ADOLPH.

**The food-stuff content of various brewery yeasts as well as of the new so-called mineral yeast.** D. MEYER. *Landw. Wochenschrift für die Provinz Sachsen* 1916, No. 45; *Z. angew. Chem.* 1917, No. 90, p. 355; *Biedermanns Zentr.* 47, 189-90(1918).—The av. crude protein content of brewery yeast is 52.74%. Calcd. on the basis of the same ash content that of the mineral yeast is 50.9%. Brewery yeast contains 38.55% pure protein; mineral yeast, 37.21%. The low content of pure protein in the mineral yeast is attributed to the low crude protein content and in the brewery yeast to the

extraordinarily high amide content. There is but slight difference in the N-free exts. (including fat and crude fiber), these being 27.91% for the brewery yeast and 25.14% for the mineral yeast. The ash of the mineral yeast contains mainly calcium phosphate; that of the brewery yeast, alkalies. Brewery yeast has an av. ash content of 7.86%, mineral yeast 18.28%.

ALBERT R. MERZ.

The nutritional physiology of alcohol and acids in yeasts and other widely distributed fungi. TH. BOKORNY. *Allgemeine Brauer-und Hopfenzeitung* 1917, No. 57, p. 747; *Z. angew. Chem.* 1917, No. 90, p. 355; *Biedermanns Zentr.* 47, 191(1918).—The alcohols and org. acids observed in fermentation are grouped together. Two tables show which of these fermentation products can serve as food for fungi and green plants. The injurious effects of the acids and of some bases are discussed. All acids hinder fermentation at a certain concn. which is high even for mineral acids. Formic and oxalic acids are the most harmful. Bases hinder fermentation more effectively than acids.

ALBERT R. MERZ.

Reducing the alcohol content of beer. H. HÄUSER. U. S. 1,286,315, Dec. 3. In reducing the alc. content of beer, a charge of beer is caused to flow in a thin film on the inner surface of a vacuum pan and the opposite side of the wall of the pan is heated by steam under pressure to boil off alc. The area of the wall to which steam is applied may be varied to regulate the process as desired.

## 17. PHARMACEUTICAL CHEMISTRY.

W. O. EMERY.

The determination of morphine in complex products. I. A revision of the analytical reactions employed. ALFRED TINGLE. *Am. J. Pharm.* 90, 689-706(1918).—All the data which might have a bearing on the analytical behavior of morphine have been studied, carefully revized and results are briefly set forth. A method has been devised, founded on these data, by which morphine in medicinal prepn. can be accurately detd. II. Mixtures containing morphine as a simple salt. *Ibid* 788-95.—A method is given for the detn. of morphine, not only in simple powders and tablets but in pills of complex compn.: Weigh a sample of 6 g. and transfer it to a 100-cc. graduated flask. Add approx. 2 g. of pure  $\text{CaCO}_3$  and mix by gently shaking, then add 20 cc. of water and warm on the water bath till a uniform, thin paste has been formed. While the warming is in progress the flask should be loosely closed by a rubber stopper. Cool the mixt., then add 60 cc. of a cold satd. soln. of  $\text{Ba(OH)}_2$ . Mix the contents of the flask thoroughly and allow to stand for 20 to 30 min. Dil. with water to 100 cc., mix well, and pour on a dry 15-cm. filter paper. Transfer the residue on the filter to a beaker, add a slight excess of  $\text{HCl}$ , warm almost to boiling, and filter. Collect as much as possible of this filtrate and conc. to about 15 cc. Test this with  $\text{FeCl}_3$  for meconic acid. Its presence indicates that any morphine in the pills being examd. is in the form of opium, in which case the method described in Part III (below) must be employed. If no meconic acid is found, transfer 50 cc. of the filtrate to a flask graduated to contain 55 cc. such as is commonly used in the analysis of sirups and sugars. Add  $\text{H}_2\text{SO}_4$  (1:5) very cautiously, till all Ba has been pptd. and the soln. is just acid to litmus. Dil. the contents of the flask to the 55-cc. mark and mix thoroughly. Allow the ppt. to settle; filter through a dry 7-cm. paper. Transfer 50 cc. of the filtrate to an evapg. dish, and add  $\text{NaOH}$  soln., drop by drop, till the stirred liquid is just alkaline to litmus paper. Add  $\text{HCl}$  with equal care till the soln. is acid once more, then evap. as rapidly as possible on the water bath till the vol. of liquid remaining does not exceed 5 cc. Do not evap. to dryness. Transfer the contents of the dish to a small sepg. funnel,

washing the dish very clean with alc. and water, used alternately, and wiping it thoroughly with a rubber-tipped glass rod. The total vol. of washings should not exceed 15 cc., of which not more than 5 cc. should be alc. Add 25 cc. of  $\text{CHCl}_3$ -alc. mixt. (2 vols. of  $\text{CHCl}_3$ :1 vol. of alc.) to the contents of the sepg. funnel, followed by a cold satd. soln. of  $\text{NaHCO}_3$ . This latter should be added almost drop by drop, till complete alkalinity is ensured, but an undue excess must be avoided. An excess tends to encourage emulsification and also unduly to dil. the aq. layer to be extd. Shake the sepg. funnel well and steadily for not less than 3 min., then allow to stand. Sepn. into layers is generally very rapid. Run the lower layer into a flask and repeat this extn. and sepn., using the same vol. of solvent and shaking for the same period. Four such extns. should always be made, but if there is any tendency to the formation of an emulsion a 5th extn. is desirable as a safeguard. The combined exts. are distd., the flask being heated on a water bath almost to dryness. Dissolve the residue in an appropriate measured quantity of 0.1  $N$   $\text{H}_2\text{SO}_4$  or a standard acid of approx. that strength (1 cc. acid = 0.0300 g. morphine is very convenient), and titrate back with 0.1  $N$  or 0.05  $N$   $\text{NaOH}$  soln. Lacmoid or cochineal is a very suitable indicator. III. **Opium and mixtures containing opium.** *Ibid* 851-61.—T. recommends the following method which can be applied equally well to dry or moist opium, to opium ash (so often a constituent of Chinese pills for the "cure" of the opium habit) or to complex pills containing these substances: Place 6 g. of the sample in a flask graduated to contain 100 cc. and digest for 10 min. on the water bath with 2 g. (approx.) of  $\text{CaCO}_3$  and enough water to form a thin paste. While warm, close the flask lightly with a rubber stopper. After digestion, cool the flask and add 60 cc. of a cold satd. soln. of  $\text{Ba}(\text{OH})_2$ . Shake the flask, now closely stoppered, at intervals. After 20 to 30 min. add water to bring the total vol. to 100 cc. Filter the soln. through a dry 15 cm. paper, and transfer an aliquot portion of the filtrate (50 cc.) to a flask graduated to contain 55 cc. (meantime the residue on the filter may be examd. for meconates as described in Part II). Add  $\text{H}_2\text{SO}_4$  (1:5) by drops till the soln. is faintly acid and no more ppt. forms, warming the flask on the water bath to promote settlement. Make the soln. faintly alk. by the cautious addition of concd.  $\text{NaOH}$ . Next, add salicylic acid, in crystals, till acidity is restored, warming the flask after each addition to induce rapid soln. of the acid. When an acid reaction has developed, add the further quantity of 0.5 g. of salicylic acid and heat the flask for 10 min. by immersion in boiling water. Allow to cool to normal temp. and add enough water to bring the contents to 55 cc. Filter the liquid through a dry 7-cm. paper, and take an aliquot portion of the filtrate (preferably 50 cc.) for further operations. Evap. the clear soln. on the water bath (best in a platinum dish) almost to dryness. Cool the dish and add enough water to make the vol. of its contents as nearly as possible 5 cc. To this add 5 cc. of  $\text{CHCl}_3$  and about 3 drops of concd.  $\text{NH}_4\text{OH}$  soln. or as much more as is needed to produce decided alkalinity. Mix the liquids well with a stirring rod by scratching the bottom of the dish lightly, thus breaking up undissolved aggregates, and promoting rapid pptn. of the morphine. When the latter substance begins to sep. cover the dish and set aside for 4 hrs., during which time it should be occasionally agitated with a rotary motion. Filter the contents of the dish through a cotton plug with the aid of suction. Wash the dish and morphine with small quantities of cold water (morphinated water may be substituted at the analyst's discretion) till the washings become colorless. About 10 cc. of water, if care is used, should suffice for this washing, in most cases. The morphine thus obtained is yellowish and not pure enough to give reliable results on titration. The plug with adherent alkaloid is lifted into a small sepg. funnel. Dissolve the morphine remaining in the dish in a small quantity of dil.  $\text{H}_2\text{SO}_4$  and transfer the soln. to the sepg. funnel through the funnel previously used for the filtration. Wash the dish and funnel with water.

Washings and acid together should not exceed 20 cc. Make the soln. of morphine sufficiently alk. to liberate all the alkaloid by the addition of either a few drops of concd.  $\text{NH}_4\text{OH}$  or a satd. soln. of  $\text{NaHCO}_3$ . Shake for 3 min. with 25-30 cc. of  $\text{CHCl}_3$ -alc. mixt. (2 vol. of  $\text{CHCl}_3$  to 1 vol. of alc.). After sepg. the lower layer of liquid, repeat the extn. on the aq. layer with 3 further similar quantities of the  $\text{CHCl}_3$ -alc. mixt., the time of shaking being 3 min. in every case. Dist. the combined exts. on the water bath. Dissolve the residue of almost white morphine in a known vol. of 0.1  $N$   $\text{H}_2\text{SO}_4$  and titrate the excess with 0.1  $N$  or 0.05  $N$   $\text{NaOH}$ . Lacmoid, cochineal or methyl orange is a suitable indicator. The wt. of morphine found by this titration will be  $\frac{10}{13}$  of that present in the original 6 g. sample, if the aliquot parts taken were those recommended above.

W. G. GAESSLER.

**Normal salt solution.** LOUIS GERSHENFELD. *Am. J. Pharm.* 90, 782-8(1918).—Results of expts. show that heating in the steam sterilizer is the best sterilization method to be employed by the average physician and practitioner so as to avoid concn. of the soln. The autoclave is to be preferred as it is undoubtedly a more effective method of rendering material sterile, while an average concn. to 0.871% of  $\text{NaCl}$  will not bear any marked relationship to the isotonicity (0.85%) of the end product. Mere boiling is not to be recommended, unless the water of evapn. be replaced by freshly distd. sterile water. Another series of expts. to ascertain what effect salt solns. of different strengths will have on the red blood cells, showed that hypoisotonic saline solns. increase the size of the red blood cells and pharmaceutically speaking may be said to have a solvent effect on these corpuscles, while hyperisotonic solns. produce a most marked toxic effect and create the erythrocytes (either by dehydrating or due to its high osmotic pressure).

W. G. GAESSLER.

**Surgeon's liquid adhesive.** E. FULLERTON COOK. *Am. J. Pharm.* 90, 808-9 (1918).—C. suggests the use of a water-sol., liquid adhesive for fastening bandages and recommends the following inexpensive and practical formula: 1000 g. liquid glue (a commercial glue, such as Dennison's, is readily obtained in bulk), 200 g.  $\text{ZnO}$ , 15 cc. oil of peppermint; mix and rub to a smooth paste.

W. G. GAESSLER.

**The percentage of stems in belladonna herb and its effect on the quality of the herb.** ARTHUR F. SIEVERS. *Am. J. Pharm.* 90, 838-51(1918).—Sprouts of belladonna were cut at 8 different stages of growth. Tabulated results (Table I) show that in the smaller sprouts cut, the 1st stage, the stems represent 18% of the total dry wt. As growth continued, this % gradually increased until it reached 41.58% at the 8th stage. Although the first material was picked when the stems were only 9 to 14 cm. long, the % which these represent by the total dry wt. is 8% more than allowed by the U. S. P., namely, 10%. The % of alc. ext. which can be obtained from the material decreases steadily from the 1st to the 8th stage. The stems show the greatest range in the amt. of ext. yielded, the highest being 44% at the 1st stage and the lowest 18.1% at the 8th stage. The leaves show a decrease of only about 10% from the first to the 8th stage. While the decrease in % of alc. ext. is general it is evident from the tables that 25% of stems may be included in the herb without reducing the % of ext. more than 6%. The % of total alkaloids also decreases through the different stages. This is decidedly marked in the stems, 0.898% being present at the first stage and 0.170% at the last stage. In the leaves the % decreases gradually and reaches the minimum of 0.537% at the 7th stage. The whole herb decreased in total alkaloids from 0.756 to 0.471% and at no stage was the % as low as the minimum 0.3% set by the pharmacopeial standard. Expts. to det. how the quality of the leaf is affected by the successive admixture of stems of certain diameter show that a mixt. of "a fair quality of herb such as is readily produced in this country containing about 20% of stems up to 7 or 8 mm. in diameter when green," contains about 10% of ash, about 23% of alc. exts., and about

0.5% of total alkaloids. S. concludes that a mix. of approx. this compn. should be a very suitable product for practically all purposes for which belladonna is marketed and suggests increasing the % of stems allowed to 20% provided it is not made possible thereby to increase the foreign matter to a similar extent. W. G. GAESSLER.

**Essential oil of *Pinus thumbergii*, Parl.** Y. SHINOZAKI. *Kōgyō-Kwagaku Zasshi* (J. Chem. Ind.) 21, 763-74(1918).—The crude oil obtained from the pine tree grown in Akita, Japan, contains 22.92% essential oil, 73.36% colophonium, 3.61% H<sub>2</sub>O and 0.21% impurities. The essential oil b. 154-252° and shows the following physical properties:  $d_{15}$  0.840,  $n_D^{20}$  1.4738,  $[\alpha]_D$  -19.17°, acid value 0.53. By fractional distn. of the purified oil *in vacuo*,  $\alpha$ -pinene (73%), camphene and a tricyclic sesquiterpene (16.6%) were isolated. The latter b. 105-6°,  $d_{20}$  0.9342,  $n_D^{20}$  1.9055,  $[\alpha]_D$  +43.5°, gave no solid compds. with HCl and HNO<sub>3</sub>. S. KOMATSU.

**Essential oil of *Amorpha fruticosa*.** Y. SHINOZAKI AND K. HOSHINO. *Kōgyō-Kwagaku Zasshi* (J. Chem. Ind.) 21, 774-81(1918); cf. Nakatogawa, C. A. 13, 384.—By steam distn. of dry fruit of *Amorpha fruticosa* grown in Manchuria, China, was obtained in 11% yield a pale yellow oil,  $d_{15}$  0.9126,  $n_D^{20}$  1.5032, sapon. value 40.51. The oil consists of a fraction b. 115-120° 48% and a fraction b. 120-125° 23%, from which codinane and another sesquiterpene, C<sub>15</sub>H<sub>24</sub>, were isolated. A sesquiterpene alc. m. 118-119° was obtained from the fraction b. 125-38°. S. KOMATSU.

**The constituents of Korean ginseng.** II. H. KONDO AND S. YAMAGUCHI. *Yakugaku-Zasshi* (J. pharm. Soc., Japan.) No. 440, 747-64(1918).—By passing steam into the ether ext. of the ginseng, a volatile oil and non-volatile substance were obtained. The latter was decompd. by alc. KOH into phytosterol m. 133-4° and fatty acids. The fatty acids sepd. from the alk. soln. on acidifying with HCl, were purified by distn. *in vacuo*, b. 220°. Solid satd. and liquid unsatd. acids were sepd. by transforming into their Pb salts. The solid part, m. 56-7°, mol. wt. 267.7, was found to consist of 44.3% stearic and 55.7% palmitic acids by Hausmann and Zulkowsky's formula. In the liquid part, linoleic acid was isolated and also confirmed by its tetrabromo compd., m. 113-4°. From 18 kg. ginseng cultivated in Aidzu, Japan, 10 g. colorless volatile oil of the compn. (C<sub>6</sub>H<sub>8</sub>)<sub>x</sub> was obtained, which shows the following properties: b. 140-143°; b. 247°,  $d_{15}$  0.9194,  $[\alpha]_D$  -5.41,  $n_D^{20}$  1.49455. In the AcOH soln., it gives with concd. H<sub>2</sub>SO<sub>4</sub> greenish brown color changing to deep green. According to the authors' expts. the ether exts. of ginseng grown in Korea and in Aidzu, Japan, contain the same constituent. S. KOMATSU.

**Hydrocyanic acid in the fern, *Gystopteris alpina* Desv.** MARCEL MIRANDE. *Compt. rend.* 167, 695-6(1918); cf. Greshoff, C. A. 3, 1764.—HCN is contained in the green parts of this fern. Under the influence of an enzyme, which acts like emulsin, the compd. containing the HCN is decompd. and upon distn. of the macerated leaves HCN and C<sub>6</sub>H<sub>5</sub>CHO are obtained, the quantity of the acid being 0.01107 g. in 100 g. of fresh leaves. When drying, the plant exhales the odor of bitter almonds.

L. W. RIGGS.

**Citronellol.** H. J. PRINS. Zaandam. *Chem. Weekblad* 15, 1378-80(1918).—Attempts to sep. citronellol (made by reduction of natural citronellal) into its isomers by fractional distn. yielded mixts. The completeness of the sepn. was checked by careful sp. gr. detns. There were 3 principal fractions which could not be further sepd. by fractionation. Their b. p. ranges and av. sp. gr. were as follows: 215-7° (0.8742); 217-9° (0.8670); 220-2° (0.8694). The variations in both properties were sufficient to indicate that neither of the fractions was homogeneous. The following constants may be assumed for the purest citronellol obtainable by this means:  $d_{15}$  = 0.867-69;  $n_D^{20}$  = 1.4586-89. It is free from geraniol. JULIAN F. SMITH.

**Zinc chloride.** T. C. N. BROEKSMIT. Haarlem. *Pharm. Weekblad* 55, 1409-10 (1918).—The  $ZnCl_2$  used in irrigating liquid is always contaminated with a basic chloride if prepd. by neutralizing  $ZnO$ ,  $Zn(OH)_2$  or  $2ZnCO_3 \cdot 3Zn(OH)_2$  with  $HCl$ . It forms a ppt. which can be removed by filtration or adding  $CaCO_3$  or  $MgCO_3$ , but either treatment decreases the concn. of  $ZnCl_2$  below the required minimum. The soln. is best prepd. by mixing thoroughly 21.1 g. of  $ZnSO_4$  and 17.9 g. of  $BaCl_2$  (both finely powdered), and adding 100 cc. of  $H_2O$ . If carefully filtered, this yields approx. an 8% soln. of  $ZnCl_2$ , free from basic salt, and giving a clear soln. in  $H_2O$ . JULIAN F. SMITH.

**The acid reaction of the juice of *Rubi idaei*.** T. C. N. BROEKSMIT. Haarlem. *Pharm. Weekblad* 55, 1410-2 (1918).—The juice of *Rubi idaei* contains  $HOAc$  and citric acid, but no tartaric nor malic acid. JULIAN F. SMITH.

**Thyroid glands.** D. VAN OS. Amsterdam. *Pharm. Weekblad* 55, 1426-31 (1918).—Unlike most pharmaceuticals, thyroid preps. are not standardized according to any adequate system. The usual plan of stating strength in germs of the wt. of the fresh glands and gaging the dose accordingly, is very unreliable because of wide variations in the amt. of fat and  $H_2O$  in the fresh glands. This is especially true of the glands from sheep. The I content of the dried, fat-free powder is fairly const. in preps. from sheep (ranging in 5 samples from 0.355 to 0.38%), but less so in those from swine (ranging in 7 samples from 0.15 to 0.266%). The Holland Pharmacopeia requirement of 0.4% should be lowered to not more than 0.3%. Expts. failed to show that I takes any part in the action of thyroid prepn. Since neither a chem. nor a physiological method of standardization is practicable, the most reliable basis for expressing the strength and calcg. the dose is the wt. of the dried, fat-free powder. J. F. S.

**The phenol occurring in the leaves of *Coleus amboinicus* Lour (*C. carnosus* Hassk).** F. WEZHUZEN. *Pharm. Weekblad* 55, 1470-2 (1918).—*Coleus amboinicus* bears a considerable reputation in the Orient as a medicinal herb. Analysis of the essential oil obtained from the leaves showed that about half the oil consists of carvacrol. The plant therefore possesses medicinal value. JULIAN F. SMITH.

KANTHACK, R.: **Tables of Refractive Indices. Vol. I. Essential Oils.** Edited by J. N. Goldsmith. London: A. Hilger, Ltd. 148 pp. 15s.

---

**Trimethyleneglycol disalicylate.** A. M. CLOVER. U. S. 1,286,944, Dec. 10. Trimethyleneglycol disalicylate,  $CH_2(CH_2O_2CC_6H_4OH)_2$ , softens  $74-5^\circ$ , m.  $77^\circ$ , colorless, odorless, nearly tasteless, insol. in  $H_2O$ , readily sol. in  $CHCl_3$ ,  $C_6H_6$ , acetone and ether and sparingly sol. in alc. and petroleum ether, is made by heating trimethyleneglycol with  $H_2SO_4$ , adding salicylic acid and heating the mixt. to  $100^\circ$ . It may be used as a remedy for rheumatism.

**Synthetic drugs.** J. TCHERNIAC. Brit. 120,081, Oct. 23, 1917. Hydroxyallylethers of *p*-acetaminophenol and its substitution products are prepd. by the reaction of alkylene halohydrins or hydroxyalkylene halohydrins in  $H_2O$  on *p*-acetaminophenol or its substitution products, in the presence of a substance fixing halogen hydride. According to an example, the  $\beta$ -hydroxyethylether of *p*-acetaminophenol is prepd. by heating ethylene chlorohydrin with a soln. of *p*-acetaminophenol in aq.  $NaOH$ .

**4-Diallylamino-1-phenyl-2,3-dimethyl-5-pyrazolone.** Soc. ANON. POUR L'IND. CHIM. A. BALE. Ger. 204,983, 1918. 4-Diallylamino-1-phenyl-2,3-dimethyl-5-pyrazolone, colorless crystals, m.  $90^\circ$ , possessing antipyretic and narcotic effect, is obtainable by the action of allyl halides on 4-amino-1-phenyl-2,3-dimethyl-5-pyrazolone in the

heat, preferably in the presence of a solvent or diluent, and with the addition of some substance to remove the acid produced.

**Salt of fructosediphosphoric acid.** BAYER & Co. Ger., 302,094, 1918. The Ca salt of fructosediphosphoric acid (from metaphosphoric esters and fructose) is only sparingly sol., but is, nevertheless, easily absorbed in the organs, and is claimed to be good in such cases as rickets.

**Amylene bromohydrin (bromoamyl alcohol).** EMIL RATH. Ger. 301,905, 1918. Mixts. of hypobromites and such acids as  $H_2BO_3$  yield with amylene ( $\beta$ -Me- $\Delta^2$ -butylene) in the cold the bromohydrin, which may be useful in the production of pharmaceutical preps.

**1,8-Dihydroxyanthranol.** BAYER & Co. Ger., 296,091, 1917. 1,8-Dihydroxyanthranol, m.  $178-80^\circ$ , a valuable agent in cases of psoriasis and other skin diseases, is prepd. by the reduction of 1,8-dihydroxyanthraquinone by means of Zn and an acid.

**Derivatives of homatropine.** CHEM. WERKE, GRENZACH. Ger. 299,806, 1917. The pharmacologically inactive homatropine can be rendered active by esterification with organic acids such as benzoic, tropic, or mandelic acid, the resulting esters (cf. *Ber.* 1918, 51, 235-52) resembling atropine in their effect on the animal organism. In this way, anhydroecgonine, hitherto valueless, can be converted into therapeutically useful products.

## 18. ACIDS, ALKALIES, SALTS AND SUNDRIES.

T. LYNTON BRIGGS.

**Science in relation to the industries of the Swansea district.** C. JOHNS. *Engineering* 106, 542, 622-3(1918).—A lecture. F. W. SMITHER.

**How to promote our (Japanese) chemical industry.** K. KONDO. *J. Chem. Ind. Japan* 21, 783-94(1918).—A lecture. S. KOMATSU.

**The fixation of nitrogen as cyanide.** Y. MORIMOTO. *Kogyo-Kwogaku-Zasshi (J. Chem. Ind.)* 21, 881-98(1918).—This is a study of Bücher's method (*C. A.* 11, 1020). The materials used were Fe turning, charcoal (3.16% to ash) and  $Na_2CO_3$  (*Jap. Pharm.*). They were briquetted in the proportions 2:2:1 or 2:2:1.35. N obtained from  $NH_4NO_3$  was passed over the briquets placed in a horizontal tube furnace heated to  $820-950^\circ$ . NaCN can easily be obtained in a yield of 75%. S. K.

**Effect of phosphine and hydrogen sulfide on the oxidation of ammonia to nitric acid.** GUY B. TAYLOR AND JULIAN H. CAPPS. *J. Ind. Eng. Chem.* 11, 27-8(1919).— $PH_3$  has a marked deleterious effect, somewhat cumulative, on oxidation of ammonia to nitric acid by catalytic platinum. Small concns. of  $H_2S$  have no immediate toxic effect.

E. M. BILLINGS.

**Treatment of crude ammonias.** A. HUTIN. *Rev. chim. ind.* 27, 147-50(1918).—A brief outline, with discussion, of processes in use for removing free S,  $(NH_4)_2SO_4$ ,  $NH_4CNS$ , and alkali ferrocyanides. The official methods (French) for the analysis of S for agricultural purposes are also given (detn. of fineness, moisture, ash, free S, insol. in  $CS_2$ ). A table is appended showing analyses of crude ammonia by Sorel and by the author, the free S content varying from 5.4 to 50.2% in the 5 lots reported. The author emphasizes the economic possibilities in the recovery and utilization of the S (by the  $Ca(OH)_2$  process). F. W. SMITHER.

**The recrystallization of niter cake.** BLAIR SAXTON. *J. Ind. Eng. Chem.* 10, 897-901(1918).—Equations have been developed for the system  $Na_2SO_4-H_2SO_4-H_2O$  at  $25^\circ$  by means of which can be calcd. (a) how much of any one solid phase will sep.

from a soln. if the compn. of the original solute and the acid concn. of the soln. after crystn. are known; and (b) the wt. of  $H_2O$  in the soln. after crystn. or the wt. of  $H_2O$  to be added to the solid niter cake in order to leave a calcd. wt. of one of the solid phases. Calcns. are also made of the max. amt. of each solid phase which can be removed from soln. at  $25^\circ$  and  $0^\circ$ . Processes are suggested whereby the  $H_2SO_4$  may be concd. in the soln. and  $Na_2SO_4$  in the solid at the 2 temps. mentioned. The sepn. can be made much more efficiently at the lower temp.

A. L. FIELD.

**Sodium sulfide and other products from niter cake.** H. P. BASSETT. *Chem. Met. Eng.* 19, 790(1918).—A discussion of some of the methods that have been proposed for the utilization of niter cake, *e. g.*, the production of  $Na_2SO_4$  by neutralizing with  $CaO$ ; the manuf. of  $HCl$ ,  $HNO_3$ , and  $H_2SO_4$ , etc. The author considers the production of  $Na_2S$  as the best soln. of the problem, and suggests that the partial oxidation taking place in Berthier's method be obviated by using C in the form of bituminous coal. The volatile matter given off keeps the furnace (of a special, air-tight design) full of reducing atm. This reaction does not require a high temp., 96% conversion being obtained at  $650^\circ$  in a cast or wrought Fe tube furnace. Means must be provided for cooling the material as discharged from the furnace out of contact with the air. As the added C is in excess of that required for the reduction, the cinder will contain some free C and will require leaching and crystallizing to recover the  $Na_2S$  in marketable form.

F. W. SMITHER.

**Some applications of ferric sulfate.** A. HUTIN. *Rev. prod. chim.* 21, 313-4 (1918).—For the prepn. of technical  $Fe_2(SO_4)_3$ , the author recommends: (1) treating pyrites cinder with warm  $40^\circ$  to  $45^\circ$  B $\acute{e}$ .  $H_2SO_4$ ; (2) fusing the cinder with  $NaHSO_4$  residue (yields a mixt. of  $Fe_2(SO_4)_3$  and  $Na_2SO_4$ ). This material is used for coagulating blood and preventing nauseous odors in abattoirs, etc., and for water purification. The economic prepn. of  $FeSO_4$  may be effected by: (1) treating  $Fe_2(SO_4)_3$  with scrap Fe; or, treating the mixt. of  $Na_2SO_4$  and  $Fe_2(SO_4)_3$  with scrap Fe, finally obtaining by crystn. a double sulfate of Fe and Na; (2) the action of  $Fe_2(SO_4)_3$  on crude pyrites ( $Fe_2(SO_4)_3 + FeS_2 + O_2 = 3FeSO_4 + 2SO_2$ ; or,  $Fe_2(SO_4)_3 + FeS_2 + 4H_2O = 3FeSO_4 + 2SO_2 + H_2$ ). The odor of  $SO_2$  is always noted, that of  $H_2S$  at times. The  $Fe_2(SO_4)_3$  used is obtained from pyrites cinder.

F. W. SMITHER.

**Seaweed as a source of iodine.** W. DOHERTY. *Chem. Eng. Mining Rev.* (Australia) 11, 53(1918).—The large brown variety of the *Laminaria*, identified as *Ecklonia radiata*, obtained in the vicinity of Sydney Heads, N. S. W., contained I in the following amts.: fresh weed 0.06, dry weed 0.40, ash 1.5%. The fresh weed yielded 4% of ash containing, besides I and Br, about 18%  $K_2O$ . Dry seaweed from other sources (coasts of Scotland, Ireland, Spain, and France) contain I as follows: *Laminaria digitata* 0.45%, *L. stenophylla* 0.48%, *L. saccharina* 0.28%, Japanese edible seaweed 0.31%. The following analysis is reported of the ash of kelp (ash produced in Scotland):  $K_2SO_4$  12.71,  $KCl$  18.09,  $NaCl$  6.8,  $Na_2CO_3$  3.5,  $Na_2S_2O_3$  0.2,  $NaI$  1.5, total  $K_2O$  18.32%.

F. W. SMITHER.

**The Canadian graphite industry.** H. S. SPENCE. Canada Dept. Mines, *Summary Rept.* 1917, 49-50.—Two deposits of graphitic shales which carry a very finely divided amorphous graphite of 25% C content are described. The flake graphite occurs in disseminated form either in cryst. limestone or in more or less calcareous bonds intercalated in gneiss. At present only 3 mines are being operated steadily while 9 mines are operated intermittently.

R. L. SIBLEY.

**The recovery of volatile solvents by simple condensation.** PONCHON. *Chimie & industrie* 1, 481-91(1918).—A review and discussion, with examples, drawings, tables, and curves, from the physico-chem. viewpoint.

F. W. SMITHER.

**Exhaust steam at high back pressures.** CROSBY FIELD. *Chem. Met. Eng.* 20, 18-24(1919).—The author gives a system of charts plotted from thermodynamical formulas, data and plant tests for use in solving heat problems with exhaust steam graphically. In illustration an 8-ton dye plant problem is given requiring a wide range of temps. in general chem. equipment, *e. g.*, steam-jacketed evapg. pans, vacuum driers, kettles and hot chambers. F. W. SMITHER.

**Patent legislation.** ANON. *Engineering* 106, 650-1(1918).—A review and discussion of a critical report of the Inst. of Elec. Engineers (also adopted by about 30 of the leading scientific and technical societies) on a bill (now abandoned) introduced into parliament about a year ago to amend the Patents and Designs Act of 1907. The contemplated legislation is to be revived and a new bill introduced. F. W. S.

**Ammonia.** NORSK HYDRO-ELEKTRISK KVAELSTOFAKTIESELSKAB. Brit. 120,034, July 13, 1918. In the manuf. of  $\text{NH}_3$  by hydrolysis of cyanamide, the  $\text{H}_2\text{O}$  used has a temp. of at least  $40^\circ$ . Considerably less  $\text{Na}_2\text{CO}_3$  is then necessary to effect the hydrolysis.

**Mono-, di- and tri-metallic alkali perphosphates and perarsenates.** S. ASCHKENASI. Ger. 299,300, 1914. By the addition of the necessary quantity of alkali to a soln. of  $\text{BaO}_2$  in aq.  $\text{H}_2\text{AsO}_4$  or  $\text{H}_3\text{PO}_4$ ,  $\text{Ba}_3(\text{AsO}_4)_2$  or  $\text{Ba}_3(\text{PO}_4)_2$  is pptd., and the filtrate contg. the per-salt is then evapd. with slight warming and under reduced pressure; an aq. soln. of a mixt. of  $\text{Na}_2\text{O}_2$  with the primary or secondary alk. salts can also be submitted to evapn. If a soln. of an arsenate, phosphate, or borate in dil.  $\text{H}_2\text{O}_2$  is evapd. to dryness with gentle warming and under reduced pressure, the corresponding per-salt, *e. g.*,  $\text{NaBO}_3$ , can be obtained with scarcely any loss of O.

**Aluminium salts.** W. B. LLEWELLYN, H. SPENCE and P. SPENCE & SONS. Brit. 119,924, Oct. 29, 1917. Addition to 112,881 (*C. A.* 12, 1111). The process of the principal patent is applied to clays, fire-clays, lithomarge, and the like, except such as contain much potash. The materials, which may be ignited if desired, are broken into small pieces for the  $\text{H}_2\text{SO}_4$  treatment, but when they are of a hard character, having a conchoidal fracture, the pieces are preferably of less thickness than would otherwise

be the case, preferably not exceeding  $\frac{1}{8}$  in. The process may be combined with the processes described in 3,805, 1912 (cf. C. A. 7, 2668), and 22,590, 1912 (C. A. 8, 996), in which case the pieces of the raw materials are treated in conjunction with underground coal-measure and like shales in the same vessel in the manner described in the specifications referred to. Cf. also 3,870, 1868.

**Calcium nitrate.** C. T. THORSSELL and H. L. R. LUNDEN. U. S. 1,286,839, Dec. 3.  $\text{CaCN}_2$  is dissolved in  $\text{H}_2\text{O}$  and mixed with a soln. of  $\text{Ca}(\text{NO}_3)_2$  and the mixt. is then treated with nitrifying bacteria and air to effect further production of  $\text{Ca}(\text{NO}_3)_2$ .

**Potassium chloride from saline waters.** G. B. BURNHAM. U. S. 1,286,932, Dec. 10. Saline waters containing K, Na, chloride, sulfate and carbonate, approx. satd. with  $\text{NaCl}$ , are cooled to cryst. out  $\text{Na}_2\text{SO}_4$  and  $\text{Na}_2\text{CO}_3$ , the liquor is removed from the deposited crystals and its temp. is sufficiently raised to evap. off a portion of the  $\text{H}_2\text{O}$  and effect crystn. of  $\text{NaCl}$  and produce an approx. satd. soln. of  $\text{KCl}$ . The latter is then sepd. and the  $\text{KCl}$  recovered from the soln. by crystn.

**Nitrates by bacterial action.** C. T. THORSSELL and H. L. R. LUNDEN. U. S. 1,286,838, Dec. 3. A porous mass of  $\text{CaCO}_3$  is treated with a soln. of  $\text{Ca}(\text{NO}_3)_2$ ; inoculated with nitrifying bacteria, the porous mass thus prepd. is then treated with a dil. soln. of  $\text{NH}_3$  or other N compds. to be oxidized and compressed air is passed through it to facilitate nitrification.

**Manganese dioxide.** M. L. KAPLAN. U. S. 1,287,041, Dec. 10. Manganous nitrate, mixed with  $\text{NaNO}_3$ , is decomposed by heating at a temp. of about  $170^\circ$  to form  $\text{MnO}_2$  and the  $\text{NO}_2$  liberated in this reaction is used to react on mineral  $\text{MnO}_2$  to produce additional  $\text{Mn}(\text{NO}_3)_2$ . The use of  $\text{NaNO}_3$  together with the  $\text{Mn}(\text{NO}_3)_2$  results in the formation of an artificial  $\text{MnO}_2$  which is readily pulverized and which is suitable for use as a depolarizing material in dry cells.

**Extracting potassium compounds from feldspar.** H. BLUMENBERG, JR. U. S. 1,286,513, Dec. 3. Feldspar is mixed with powdered  $\text{CaCO}_3$  and with acid sludge produced in refining petroleum with  $\text{H}_2\text{SO}_4$  and the mixt. is heated in air to form  $\text{K}_2\text{SO}_4$  and an insol. Ca Al silicate. Temps. of  $700$ – $1000^\circ$  are employed.

**Decomposing potassium-bearing silicates.** H. N. MORSE. U. S. 1,286,718, Dec. 3. Silicates, such as feldspar which has been treated with caustic alkali, which contain K and Al and which are attacked by  $\text{SO}_3$  are heated in a current of  $\text{SO}_3$  to a temp. (preferably about  $250^\circ$ ) at which the  $\text{SO}_3$  reacts with the K but not with the Al.  $\text{K}_2\text{SO}_4$  is formed and then oxidized by the air to  $\text{K}_2\text{S}_2\text{O}_8$ .

**Acid-resisting compositions.** CHANCE & HUNT, A. E. HOLLEY and H. W. WEBB. Brit. 119,966, Jan. 12, 1918.  $\text{PbCO}_3$  or basic Pb carbonate is added to ground acid-resisting siliceous material and then mixed with  $\text{Na}_2\text{SiO}_3$  soln. Proportions are: finely ground stoneware 8, sand 7, less finely ground blue brick 2,  $\text{PbCO}_3$  0.25,  $60^\circ$  Tw.  $\text{Na}_2\text{SiO}_3$  soln. 3.

**Hydrogen peroxide.** R. MORITZ. Brit. 120,145, Oct. 8, 1918.  $\text{H}_2\text{O}_2$  is produced by hydrogenating a tube, ribbon, or wire of Pd or a Pd alloy and then acting with it upon a soln. of O in  $\text{H}_2\text{O}$  or weak  $\text{H}_2\text{O}_2$ . The process may be carried out by passing an endless Pd ribbon or wire through an atm. of H and then through a tube lined with ebonite and contg. a soln. of O; or by passing H through a Pd tube immersed in an O soln. in an Fe tube lined with ebonite; or electrolytically by passing a stream of acidulated  $\text{H}_2\text{O}$  satd. with O over a cathode of Pd or Pd alloy and an anode of Pt, Au, fused Fe oxide, graphite, etc., with or without a diaphragm, preferably in a horizontal Fe tube lined with ebonite, Sn, Ag, rubber, etc. In all cases, the H may be replaced by mixts. such as water-gas and the H and O or air may be under pressure.

**Titanium oxide.** TITANIUM ALLOY MFG. CO. Norw. 28,673, Mar. 25, 1918. The initial material is fused in the presence of a sulfide and an alkali metal, obtaining thereby ferro-Na-sulfide and alkali titanate. The mass is maintained in a molten state until it seps., by gravity, into two portions, one containing more Ti and less Fe than the other.

**Hydrogen.** H. KELLER. U. S. 1,286,650, Dec. 3. H is produced by alternately passing steam and a reducing gas at a high temp. over spongy Fe which has been produced by embedding an O-compd. of Fe, *e. g.*,  $\text{Fe}_2\text{O}_3$ , in C and heating. "Swedish Fe sponge" may be used.

**Nitrogen from combustion gases.** M. SHOELD. U. S. 1,287,472, Dec. 10. A gaseous mixt. containing N and  $\text{CO}_2$ , *e. g.*, gases produced by combustion of coke, is scrubbed with an absorbent of  $\text{CO}_2$  such as  $\text{K}_2\text{CO}_3$  soln. to remove the  $\text{CO}_2$  and obtain N. The soln. obtained is then heated to drive off  $\text{CO}_2$  and the residual soln. then may be reused for further absorption of  $\text{CO}_2$ .

**Aluminium compounds.** NORSK HYDRO-ELEKTRISK KVAELSTOFAKTIESELSKAB. Brit. 120,035, July 23, 1918. Al compds. are prepd. from clay, argillite, or similar minerals by treatment with acids in an autoclave under pressure. When  $\text{HNO}_3$  is employed, the pressure is stated to prevent dissociation at the temp. employed. The silicic acid is said to be obtained in a grainy state, and readily separable by filtration.

**Oxygen practically from free chlorine.** CHEM. FABRIK GRÜNAU, LANDSHOFF & MEYER, E. FRANKÉ and F. SCHMIEDT. Ger. 299,505, 1915. By the addition of a small quantity of Ni or Co in the form of metal, oxide, or salt, the "first period" of development of O from chlorates or perchlorates is prolonged;  $\text{CeO}_2$  also can be used as catalyst. The last traces of Cl can be removed from the gas by passing this through a filter of  $\text{MgO}$ , whiting, or anhydrous  $\text{Na}_2\text{CO}_3$ , which may be distributed over some inert material, such as glass wool or asbestos.

**Decolorizing carbon.** R. W. MUMFORD. U. S. 1,287,592, Dec. 10. Decolorizing C adapted for use in decolorizing oils or sugar solns. is produced by placing a dough-like mass of comminuted vegetable material such as coal, peat, sawdust or lignite, mixed with starch or molasses, in thin layers, in mixt. with pulverized dolomitic limestone and heating progressively to above  $800^\circ$ , dumping the carbonized product into  $\text{H}_2\text{O}$  while excluding air, removing the mineral matter by sedimentation and then drying the carbonaceous material obtained.

**Carbon-removing composition.** C. A. LEWIS. U. S. 1,287,589, Dec. 10. A mixt. adapted for removal of C from internal-combustion engines is formed of acetone 50% or more, alc. 15-40%,  $\text{H}_2\text{O}$  3-20% and oil of citronella 3% or less.

**Phenolic-formaldehyde condensation product.** J. O. HANDY. U. S. 1,287,299, Dec. 10. A mixt. of commercial "cresylic acid" of 97-99% purity is boiled with such a proportion of 40%  $\text{CH}_2\text{O}$  soln. that the mixt. contains more than one mol.  $\text{CH}_2\text{O}$  for each mol. of cresylic acid and the boiling is continued until the solids, detd. at a temp. of  $110^\circ$ , equal at least 40% of the product and are infusible, hard and tough and insol. in acetone. The final boiling during which  $\text{H}_2\text{O}$  and  $\text{CH}_2\text{O}$  are distd. off is conducted at a temp. of  $110-120^\circ$ . The product obtained by this method is suitable for use as a binder in making brushes and for various other purposes.

**Plastic composition.** J. SANDERSON. U. S. 1,287,453, Dec. 10. A mixt. suitable for use in surgical work and for other purposes is composed of plaster of Paris 41, boiled linseed oil 2, resin 11 and carnauba wax 3 parts.

**Molded electrical insulation from pitch.** J. P. A. MCCOY. U. S. 1,286,370, Dec. 3. Coal-tar pitch is heated sufficiently to drive off its more volatile constituents, preferably at a temp. of about  $260-300^\circ$ , finely divided, then treated with  $\text{C}_2\text{H}_4$  or other

liquid which will cause swelling and softening of the material and molded under pressure. The product is especially intended for use as a binder with fillers such as wood flour or asbestos.

**Molded mixture of sodium silicate and portland cement.** J. P. A. McCoy. U. S. 1,286,371. A dry mixt. of Na or K silicate 1-20 and portland cement 99-80 parts is moistened sufficiently for molding but not sufficiently to dissolve the silicate, the moistened material is molded and the molded article then is subjected to the action of steam to indurate the mass. The material thus formed is suitable for use as a binder with various fillers.

**Electrical insulation.** J. P. A. McCoy. U. S. 1,286,372, Dec. 3. A material suitable for use as an elec. insulation is formed by mixing about equal amts. of pyrogallol and gum arabic with about 5% their weight of trioxymethylene and about 50% of a filler such as sawdust, asbestos or wood flour and then compressing the mixt. in a hot mold.

**Effecting catalytic reactions.** J. WALTER. Ger. 296,507, 1917. Thorough exposure of the catalyst to the reagents is achieved by electromagnetic means. The catalyst itself may be magnetic and if desired spread on a non-magnetic material, or a non-magnetic catalyst may be deposited on a magnetic substance, and parts of the app., such as baffle plates or gauze in a gas tube, or mechanical agitators, are made magnetic or magnetizable. During the reaction, or during the removal of the products, magnetic fields are established and broken by elec. means, so that the catalyst is kept moving, but near the exit of the app. a permanent field is maintained to prevent loss of the agent as dust. Examples given in the original specification include the hydrogenation of train oil, the prepn. of  $\text{CH}_4$  from CO, and the reduction of cinnamaldehyde to  $\beta$ -phenylpropaldehyde and  $\beta$ -phenylpropyl alc., levulose to mannitol, and quinine to di- and tetrahydroquinine.

## 19. GLASS AND CERAMICS.

G. E. BARTON AND A. V. BLEININGER.

**The effect of certain impurities in causing milkiness in optical glass.** C. N. FENNER AND J. B. FERGUSON. *J. Am. Ceram. Soc.* 1, 468-76(1918).—In connection with optical glass making at Bausch & Lomb Optical Co. there was occasional but irregular occurrence of opalescence or milkiness in the light flint glass (containing about 33.5%  $\text{PbO}$  and with  $n_D =$  about 1.572). The cause was sulfate and chloride in Russian potash used after the German supply was exhausted. Even with such impurity no trouble resulted after reliable temp. control was instituted and a finishing temp. of 1400-1420° was maintained. Analyses of potash and of glass samples are given. One analysis of a milky glass showed 0.14%  $\text{SO}_2$  which, after clearing up by heat treatment at 1100° or a little higher, showed only 0.06%  $\text{SO}_2$ . In another case 2 pots of glass made alike except for some possibility of slight temp. difference showed 0.10%  $\text{SO}_2$  and 0.17% Cl for one portion which was milky and 0.05  $\text{SO}_2$  and 0.17% Cl for the other which was clear. Probably the Cl is much less objectionable than the  $\text{SO}_2$ . The milkiness is not due directly to the  $\text{SO}_2$  or Cl but to some result which their presence favors. Evidence indicates that the minute particles causing milky color are submicroscopic crystals of crystalbite. C. H. KERR.

**Effects of heat on chemical glassware.** R. G. SHERWOOD. *J. Am. Chem. Soc.* 40, 1645-53(1918).—In exhausting to high vacuum it is common practice to heat vessels to 200 to 400°. The large quantities of gaseous products obtained can hardly be due entirely to surface adsorption. Expts. are described. Two kinds of gaseous evolution

were found: (1) adsorbed products readily removed below  $300^{\circ}$ , (2) from chem. decompn. of the glass itself, this becoming important above  $400^{\circ}$  for softer glasses (ordinary Na and Pb glasses) and above  $500^{\circ}$  for harder glass (Corning G702P). There seems to be a definite characteristic rate for each temp. C. H. KERR.

**Investigation of clay and shale resources of Canada.** J. KEELE. Canada Dept. Mines, *Summary Rept.* 1917, 97-120.—Results are given on absorption, fire shrinkage tests and color after heating samples from a number of clay deposits in various Canadian provinces. Descriptions of many of the clay beds are also included. A large bed of diatomaceous earth is reported in British Columbia. The earth is a soft, white, chalky material, with little or no plasticity when wet. It makes a good insulating brick when mixed with 25% of good plastic clay and some sawdust, and then molded and burned as in ordinary brick making. Clays suitable for the manuf. of tableware, stoneware goods, art pottery, and flowerpots are also described. The manuf. of magnesite brick is described with chem. analysis of several bricks. Lightly calcined magnesite when wet in amts. varying from 6 to 15% will cohere for molding and can be made into brick shapes. If dead-burned magnesite is ground fine it is possible to mold it in a damp state without a bond in presses. Various samples of quartzite and sandstone were tested to det. their suitability for the manuf. of silica brick. The results showed that there was a tendency to undue swelling under heat treatment common to quartzites. The addition of an impalpable powder to good quartzite was found to make an improvement in the strength of the bricks when burned. Cf. C. A. 12, 1505.

R. L. SIBLEY.

**Semi-translucent illuminating glass.** J. O. HANDY. U. S. 1,287,005, Dec. 10. A white semi-translucent illuminating glass free from "fire" is formed by fusing together a foundation lead soda batch with  $\text{Al}(\text{OH})_3$ ,  $\text{Na}_2\text{SO}_4$ ,  $\text{Na}_2\text{PO}_4$  and NaCl.

## 20. CEMENT AND OTHER BUILDING MATERIALS.

C. N. WILEY.

Two letters on effect of coal ash on the nature of cement mill potash. A. E. ANDERSON and R. J. NESTELL. *J. Ind. Eng. Chem.* 10, 1030-3(1918).—Exception is taken to assertions made by Potter and Cheesman (C. A. 12, 756) that  $\text{H}_2\text{O}$ -sol.  $\text{K}_2\text{O}$  in fume from cement stacks is largely from the insol.  $\text{K}_2\text{O}$  in the coal dust and raw material; also that  $\text{K}_2\text{O}$  content of coal ash must be figured in calculating liberation. The authors demonstrate (1) that the coal used in cement burning carries comparatively small amts. of  $\text{K}_2\text{O}$ , the av. being only 0.24% for 9 plants investigated, (2) that the amt. of coal-ash  $\text{K}_2\text{O}$  introduced into the kiln is ordinarily very small as compared with amt. of  $\text{K}_2\text{O}$  entering the kiln with the raw material, and (3) that the sum of the insol. and slowly sol.  $\text{K}_2\text{O}$  collected from coal-burning kilns exceeds the sum of the total  $\text{K}_2\text{O}$  contained in the coal and in the raw material mechanically blown from the kiln. B. E. O. RHODES and J. J. PORTER. These authors also contest conclusions drawn by Potter and Cheesman and cite expts. made at the plant of the Security Cement & Lime Co. in Maryland, concluding that the effect on  $\text{K}_2\text{O}$  liberation is not greatly influenced by the low percentages of  $\text{K}_2\text{O}$  in coal used and that by addition of NaCl to raw mixt. the % of  $\text{H}_2\text{O}$ -sol.  $\text{K}_2\text{O}$  in "treater dust" increases at the expense of the acid-sol.  $\text{K}_2\text{O}$ . C. N. WILEY.

The nature of the recombined potash in cement-mill dust. ALBERT R. MERZ and WILLIAM H. ROSS. *J. Ind. Eng. Chem.* 11, 39-45(1919).—The recombined potash of cement-mill dust occurs in the form of a potash slag or impure glass and is due to a

recombination of a portion of the potash volatilized in kiln practice with the ash of the coal used for fuel and to a lesser extent with the siliceous material originally occurring in the raw mix. The extent of recombination would probably be reduced by burning the cement under oxidizing rather than reducing atm. conditions and by any procedure that would introduce  $\text{CaO}$  or  $\text{NaCl}$  into the dust at the hottest part of the kiln. The greater the amt. of potash volatilized the lower will be the proportion that will undergo recombination in the dust.

ALBERT R. MERZ.

**Waterproofing cement.** D. DAVIDSON. U. S. 1,285,636, Nov. 26. About 0.25-1.00% of naphthenic acids such as are obtained in refining Russian petroleum are added to cement as a waterproofing agent. The acids may be allowed to combine with the lime of the cement or  $\text{BaCl}_2$  or  $\text{AlCl}_3$  may be added to form insol. naphthenates of Ba or Al.

**Artificial stone.** W. WEILER. Swed. 43,945, Apr. 17, 1918. Peat is disintegrated by freezing, the mass is mixed with a binder such as cement, and molded.

**Treating wood.** L. PATERSEN-HVID. Swed. 43,965, Apr. 24, 1918. In a process of preserving and coloring wood, the articles are subjected to the action of steam in a closed vessel together with  $\text{NaOH}$  or the like, which collects at the bottom of the vessel, and  $\text{NH}_3$  which serves to neutralize the organic acids formed by the action of the steam, the volatile  $\text{NH}_3$  salts being decomposed by the  $\text{NaOH}$  with the liberation of the  $\text{NH}_3$  for continued action.

## 21. FUELS, GAS, TAR AND COKE.

J. D. PENNOCK.

**The fusibility of coal ash and the determination of the softening temperature.** A. C. FIELDNER, A. E. HALL, AND A. L. FEILD. U. S. Bur. Mines, *Bull.* 129, 118 pp. (1918).—An exptl. study reported in detail with a review of the literature, discussions, illustration, curves, tables, etc. "The publication gives the effect of various oxidizing, reducing, and neutral atms. such as are found in various parts of the fuel bed on the softening temp. of ash when molded in the form of Seger cones. A practical method of detg. fusibility has been developed whereby the ash is caused to soften and form slags in which the Fe exists in approx. the same state of oxidation as the Fe in fuel-bed clinkers. Although it is believed that this method will indicate the probable clinkering characteristics of a coal better than any fusion tests heretofore described, the bureau does not recommend the general use of this method in coal specifications until it is justified by actual trial in furnace tests of different coals. As no fusibility test of a well mixed sample of the av. ash of a coal takes into account the physical distribution of the impurities in the coal as burned, much additional investigation is needed to establish the exact relation of these lab. fusibility tests to clinker formation." *Summary and conclusions:* "Attention is called to the empirical nature of the 'fusing or softening-temp.' test and the necessity of adopting some standard and duplicatable method if it is to be used in specifications for the purchase of coal. The influence of the more important factors affecting the softening temps. of the coal ashes tested are: *Fineness of ash:* Ash ground to an impalpable powder tended to soften at a slightly lower temp. than ash that would pass a 100-mesh screen. The difference averaged  $6^\circ$ , and in no test exceeded  $40^\circ$ . Ash pulverized to at least 200-mesh was preferred, as it could be molded into more substantial cones than 100-mesh material. *Inclination of cones:* Mounting the cones with a considerable inclination ( $35^\circ$  or  $40^\circ$  from the vertical) caused premature deformation points in some cones, which bent only at or near the

base at a comparatively early stage in the fusion process, before the ash had softened to the flowing point. Vertical or nearly vertical cones were more free from this source of variation. Horizontally mounted cones usually gave lower softening points than vertical cones, the difference varying from  $0^{\circ}$  to nearly  $200^{\circ}$ . The av. difference for 15 samples was  $49^{\circ}$ . In general, horizontal or inclined cones indicated a softening point at too early a stage in the fusion process; hence vertically mounted cones are recommended. *Size and shape of cone:* The deformation of a cone depended to some degree on its size and shape. Within limits of 0.5–2.5 in. high the actual size had little influence provided the shape was the same, *i. e.*, the ratio between the dimensions of the base and of the altitude. Cones made of coal ash did not bend as uniformly as the standard pyrometric cones. Attempts to modify the ratio of base to altitude in order to obtain a more uniform deformation, like the usual Seger-cone bend, resulted in the selection of a rather slender type of cone—each side of base  $\frac{3}{16}$  in.; altitude, 1 in.—as having less tendency to soften to a lump without a bending. Later experience showed that certain ashes when molded into slender cones would bend when only a relatively small part of the ash mixt. had fused, thus indicating a premature softening temp.; it was also impossible to prevent some ashes from fusing down to a lump even with the slender type of cone. It was, therefore, decided to eliminate entirely the bending tendency by increasing the width of the base; and to take as the softening temp. the point where the cone had softened and flowed down to a somewhat spherical lump. The optimum size for this purpose was found experimentally to be a cone  $\frac{3}{4}$  in. high and  $\frac{1}{4}$  in. wide at the base. This end point was found reproducible within  $30^{\circ}$ , and was practically free from the occasional large variations experienced with the slender bending cones. *Carbonaceous matter in the ash:* Tests in which all traces of C were removed and in which the cones were made up exclusively with distd.  $H_2O$ , showed no appreciable difference in softening temp. when compared with similar tests in which the same ashes were made into cones with 10% dextrin soln. which was not burned out before the cones were inserted in the furnace. These tests were made in atms. of air, of H and  $H_2O$  vapor, and of CO and  $CO_2$  at rates of heating not exceeding  $5^{\circ}$  per min. In certain tests in the gas furnace with a reducing atm., more rapid rates of heating caused swelling and intumescence, which was much less pronounced when the ash was previously ignited in O for 2 hrs. In routine work, ignition of the reground ash in O promotes more definite and reliable softening points, especially when the original ash has been incompletely ignited. *Rate of heating:* In general, slower rates of heating gave lower softening points. Rates slower than  $2^{\circ}$  or faster than  $10^{\circ}$  per min. are not advisable. The effect of variations between these limits in purely oxidizing atms. was negligible. In a reducing atm. of H the lowest and most uniform results were obtained with a heat increase of  $2^{\circ}$  per min.; however, a temp. increase of  $5^{\circ}$  per min. until initial deformation of the cone occurred, and then reducing the rate to  $2^{\circ}$  per min. gave practically the same results and saved considerable time in making the test. In the gas furnace with reducing atm., the optimum rate of temp. increase was between  $5^{\circ}$  and  $10^{\circ}$  per min. These limits are recommended for a standard rate of heating. *Oxidizing or reducing atm.:* The atm. in which the ash was heated proved by far the most important factor in causing large variations in the softening temp. The highest softening points were obtained either in an atm. of air (Pt-wire resistance furnace), or in a strongly reducing atm. of CO (Northrup furnace), which prevented the Fe oxide from acting as a fluxing agent by reducing it to metallic Fe before the softening of the ash began. The lowest softening temps. were obtained in those atms. of mixed gases in which reduction of  $Fe_2O_3$  proceeded mainly to FeO, the most active phase in the reduction of Fe ore as regards slag formation at lower temps. The max. variation in softening temps. due to differ-

ent atms. ranged from  $134^{\circ}$  to  $396^{\circ}$ . *Fusibility of ash in various mixts. of H and H<sub>2</sub>O vapor:* The softening temps. of 5 different coal ashes were detd. in various mixts. of H and H<sub>2</sub>O vapor, ranging from 100% H to 100% H<sub>2</sub>O vapor. These results, plotted in the form of curves, showed that for each of the ashes tested there was a high softening temp. in pure H on one end owing to reduction of Fe oxide to metallic Fe; similar high softening temp. in H<sub>2</sub>O vapor or air on the other end owing to the Fe oxide remaining for the most part in the form of Fe<sub>2</sub>O<sub>3</sub> or Fe<sub>3</sub>O<sub>4</sub>; and a somewhat lower softening temp. in the middle part; in an atm. ranging from 30 to 70% H<sub>2</sub>O vapor, owing to the reduction of most of the Fe to the Fe<sup>++</sup> state, in which it combined to form fusible Fe<sup>++</sup> silicates. *Fusibility of ash in various mixts. of CO and CO<sub>2</sub>:* Softening-temp. tests in various mixts. of CO and CO<sub>2</sub> were also made with 4 of the ashes that had been tested in mixts. of H and H<sub>2</sub>O vapor. Softening-temp. curves similar to the curves obtained in tests with atms. of H and H<sub>2</sub>O vapor were obtained, each having a minimum region of fusion between approx. limits of 75 and 10% CO. It was found necessary to heat the ash cones more slowly in CO-CO<sub>2</sub> atms. to attain approx. the same minimum point as was found in H<sub>2</sub>-H<sub>2</sub>O atms. at faster rates of heating. Even with a slower rate of heating in the former atm. the av. difference in the minimum softening temps. (down points) of a series of ashes tested in the 2 atms. was  $66.1^{\circ}$ . The max. difference was  $197^{\circ}$ . The results obtained in H<sub>2</sub>-H<sub>2</sub>O atms. were generally lower than in CO-CO<sub>2</sub> atms. The initial deformation points were practically the same in CO-CO<sub>2</sub> and in H<sub>2</sub>-H<sub>2</sub>O atms. *Fusibility of ash in the reducing atm. of a gas furnace:* It was found possible so to operate 2 types of gas furnaces, in which the combustion products had free access to the coal ash, that an atm. of approx. 60% oxidizing and 40% reducing gases was maintained around the coal ash. Softening temps. similar to those previously obtained in mixts. containing equal parts of CO and CO<sub>2</sub> were thus obtained in a much simple type of furnace. By operating the gas furnace with the max. excess of gas over air, the desired reduction of Fe<sup>+++</sup> to Fe<sup>++</sup> was obtained without the production of any metallic Fe. *State of oxidation of Fe in ash cones fused in various atms:* Ash cones fused in oxidizing atms. of air, CO<sub>2</sub>, and H<sub>2</sub>O vapor contained 67 to 88% of the total Fe in the Fe<sup>+++</sup> form; in reducing atms. of H and CO, 49 to 78% of the Fe was present as metallic Fe. In mixts. containing equal parts of H<sub>2</sub> and H<sub>2</sub>O or of CO and CO<sub>2</sub>, 78 to 94% of the Fe was present as Fe<sup>++</sup>. *State of oxidation of Fe in clinker and slags:* Analyses of clinker-slugs from 2 different boiler furnaces and one hand-fired exptl. furnace showed that fuel-bed conditions are such as to favor the formation of clinkers containing Fe principally in the Fe<sup>++</sup> state as was found in ash cones fused in mixts. of equal parts of H<sub>2</sub> and H<sub>2</sub>O or of CO and CO<sub>2</sub>. *Standard method of detg. the softening temp. of coal ash:* The method of detg. the softening temp. of coal ash in a gas furnace with a reducing atm. is recommended as a standard method. The furnace is simple, it can be easily operated, and a no. of tests can be made simultaneously. When a furnace is operated under the prescribed reducing conditions reproducible results can be obtained, approximating those of the more definite mixts. of equal proportions of CO and CO<sub>2</sub>. A standard furnace design and procedure are recommended."

F. W. SMITHER.

*Fusibility of coal ash in West Virginia coals.* WALTER A. SELVIG. *Chem. Met. Eng.* 19, 826-8(1918).—Test made at the Bur. of Mines to det. clinkering properties of certain coals for industrial use. The method employed was the standard gas furnace method of the Bur. of Mines (cf. preceding abstract). The coal samples, ground to 60-mesh, are placed in shallow fire-clay roasting dishes and completely ashed at a temp. of  $800-900^{\circ}$ . This ash is then ground in an agate mortar to pass a 200-mesh sieve. To ensure complete ashing, the ash is then placed in fused silica capsules and ignited at  $800^{\circ}$  for 2 hrs., O being passed through the furnace meanwhile. A portion of the ash is

transferred to an agate mortar, moistened with a 10% dextrin soln. and worked into a plastic mass with a spatula. It is then molded into solid triangular pyramids 0.75 in. high by 0.25 in. wide at the base. These cones are then removed, dried and mounted in a vertical position in a refractory base made up of a mixt. of 2 parts kaolin to 1 of calcined alumina. Usually 5 cones are mounted in the same base. The base with the cones is dried over a hot plate until all  $H_2O$  is driven off; then the dextrin is burned out of the cones by igniting them in a muffle furnace at a dull red heat, after which the cones are ready for use. The furnace used was a No. 3 melter's furnace of the American Gas Furnace Co., natural gas and air pressure of 2-3 lbs. to the sq. in. being used. The cones, on a suitable mounting, are placed within a covered fire-clay crucible. For observation purposes a fused silica tube with a thin glass window is placed in a 2-in. hole drilled through the furnace jacket and fire-clay crucible. At right angles to this a 0.25 in. hole is drilled through the furnace and crucible, through which a Pt-Rh thermocouple, protected by a glazed porcelain tube, is inserted. A reducing atmosphere is maintained within the furnace by using the min. amt. of air necessary for combustion. Under these conditions, the iron in the ash is reduced to the ferrous state, which condition gives the lowest melting points and therefore the lowest temp. at which clinkering may result. The temp. is gradually increased to  $800^\circ$  when the rate is slowed down to not less than  $5^\circ$  nor more than  $10^\circ$  per min. and maintained to the end of the test, when a max. temp. of  $1500^\circ$  ( $2732^\circ F.$ ) is attained. If higher temps. are needed to fuse the cones, a Mo wire resistance furnace with an atm. of H can be used. However, a coal whose ash fuses above  $2730^\circ F.$  should cause little trouble due to clinker formation. The temp. readings taken were: (1) The initial deformation temp. The temp. at which the first bending of the apex of the cone takes place. (2) The softening temp. The temp. at which the cone has fused down to a spherical lump. A summary of tests on W. Va coals, including the Monongahela, Conemaugh, Allegheny and Pottsville, is given.

J. L. WILEY.

(Carbon disulfide elimination from benzene.) Inaugural address (Midland Section Gas Engineers). J. A. WILSON. *Gas World* (Coking and By-Products Sec.) 69, No. 1794, 13-15(1918); *Gas. J.* 144, 465-7(1918).—W. described his process for eliminating S present as disulfide from com. benzene (cf. C. A. 11, 703). The method consists in washing with NaOH at a temp. just below the b. p. of benzene. The following details of a complete washing are given: Forerunnings charged to mixer 1241 gals., sp. gr. 0.907,  $CS_2$  8.83%. First wash NaOH 715 gals. of  $27.5^\circ Tw.$ , sp. gr. after run 0.892,  $CS_2$  3.57% = 59.55% reduction. Second wash. Treated spent liquor from first wash 550 gals., sp. gr. after run 0.885,  $CS_2$  0.396% = 35.96% reduction. Total disulfide removed = 95.51%.

The rational utilization of coal. RENÉ MASSE. *Chimie & Ind.* 1, 665-73(1918).—A plan for conserving the coal resources of France by gasifying the entire production, recovering the by-products, and utilizing the gas and tar oils in engines for production of elec. energy. M. advocates placing all the plants under centralized control and at central stations located at the mines.

J. L. WILEY.

A rapid volumetric method for the determination of sulfur in coal and coke. R. M. STRICKER. *Chem. Analyst* 26, 6(1918).—Ignite 1 g. pulverized coal or coke in a Pt crucible with 1 g. Eshka mixt. until all the C is consumed. Place the residue in a 120-cc. beaker, wash the crucible with 25 cc.  $H_2O$ ; boil 2 min. and decant through a filter. Wash with 2 more 25-cc. portions., finally wash with 10 cc.  $H_2O$  and discard both residue and filter. Add 2 drops HCl in excess to acidify filtrate, add 25 cc. benzidine reagent (6.7 g. benzidine in 18 cc. 1.17, HCl dild. to 1000 cc.), stir rapidly during the addition, allow to settle 15 min. in cold  $H_2O$  or until at about  $20^\circ$ , filter, wash three times with cold  $H_2O$  (15 cc.). Transfer the filter to a 350 cc. erlenmeyer, add 100 cc.

H<sub>2</sub>O and agitate until the paper is disintegrated. Add several drops phenolphthalein and titrate with standardized Ba(OH)<sub>2</sub>. Just before the end point is reached, boil 3 min. and carry the titration to a faint 5 min. pink. H. M. LANCASTER.

Peat in 1917. C. C. OSBON. U. S. Geol. Survey. *Mineral Resources of U. S.*, 1917, Part II, 257-83 (Preprint No. 20, published Dec. 19, 1918). E. H.

Power alcohol—proposals for its production and utilization in Australia. THOMAS R. LYLE, *et al.* Commonwealth of Australia, Advisory Council of Sci. and Ind., *Bull.* 6, 69 pp.(1918).—Owing to the fact that Australia has as yet no domestic supply of mineral oils, and to the fact that the price of such oils, which at present are imported, has steadily risen, a committee was appointed to investigate the production and use of alc. as a fuel for internal-combustion engines. It is concluded that: The world's supply of liquid mineral fuels is not sufficient to meet the demand which is rapidly increasing. Enterprises for the production of mineral oils in Australia have not so far proved successful. Climatic conditions in that country are, however, favorable for the growth of plants containing sugars and starches, from which alc. can be manufd. Alc. is in every way suitable for use as a liquid fuel, and possesses certain advantages over petroleum. The calorific value of alcohol is 11,000 B. t. u. per lb., compared with 18,500 B. t. u. for petroleum. But owing to the greater degree of compression that can be used with alcohol without danger of pre-ignition, a thermal efficiency of 30% can readily be obtained in a properly designed alc. engine, as against 20% in a petroleum engine. From a technological standpoint, the most suitable raw material at present available is the sugar molasses now wasted in Queensland. Since the one source would not meet requirements the cultivation of sorghum grain was suggested as being desirable. The results of the engine tests show that alc. can be used with entire success in internal combustion engines. The distillates obtained from coal-tar oil at a temp. of 170-230° meet the requirements of a good denaturant for alc. to be used as a fuel.

J. H. YOUNG.

Crops for the production of power alcohol. W. R. GRIMWADE. Commonwealth of Australia, Advisory-Council of Sci. and Ind., *Bull.* 7, 153-61(1918).—The importance of alc. as a substitute for gasoline is pointed out and data are presented regarding price, source, and production of alc. The factors influencing the selection of a crop for its production are fully outlined, and stress is placed upon the fact that the commercial success of the industry rests mostly with the proper choice of the crop.

Manufacture of benzene from coal gas. G. F. VAN LIMBORCH VAN DER MEERSCH. Amsterdam. *Het Gas* 38, 124-6(1918).—A description and diagram of an installation for recovering the volatile oils from 60,000 cu. m. of gas per day. J. F. S.

Benzene and naphthalene recovery. HAROLD E. COPP. *Gas J.* 144, 311-3 (1918); *Gas World* 69, 265-6(1918).—The method described performs the double function of removing the benzene as well as the naphthalene from the gas by means of creosote. The benzene plant is situated at the inlet to the purifiers and comprises scrubber, heat exchanger, oil superheaters, crude benzene still using live steam, analyzer, main

condenser, separator, and oil coolers. The process is continuous. To sep. the naphthalene fractions from the crude benzene a small supplementary condenser has been installed between the still and the main condenser. In this new member, a very fine regulation of temp. at 92-98° has to be ensured; this is realized by its smallness and structural details. It is interesting to note that while the crude gas at the inlet of the oil scrubber contains an av. of 16.8 grains of naphthalene per 100 cu. ft. of gas, the scrubber had absorbed the whole of the naphthalene. From 24-30 lbs. are recovered every day, this being the equiv. of 16 grains per 100 cu. ft. The remaining 0.8 grain passes with the crude benzene to the storage tank. Since the introduction of the small condenser, the naphthalene content of the wash oil has been reduced from 20-25% to only 6%. The wash oil is kept in better working condition and lasts longer. The quality of the benzene is also improved; it formerly avgd. about 51% and has now risen to 71%. The working of the purifiers has also improved, the material showing no signs of the presence of naphthalene. Since the process was started no vaporized oil has been introduced into the gas.

**Low-temperature distillation of Illinois and Indiana coals.** G. W. TRAEER. *Bull. Am. Inst. Mining Eng.* 1919, 98; cf. *C. A.* 13, 255.—In reply to discussions T. emphasizes the economy of his process as regards initial cost and operating requirements. Observations already made indicate a "through-put" of at least 12 tons for each oven per day.

J. L. W.

**Estimation of naphthalene in coal gas.** HAROLD G. COLMAN. *Gas J.* 144, 231-2 (1918).—It has been found advisable to modify the method published by Colman and Smith 18 yrs. ago (cf. *Gas J.* 75, 798). The app. consists of 4 wash-bottles in series; the first is of glass with glass stopper, the second preferably a narrow-mouthed bottle of about 250 cc. capacity fitted with a rubber stopper carrying an inlet and outlet tube. All connections should be of glass tubing as naphthalene is rapidly absorbed by rubber. The first bottle is charged with a 10% soln. of citric acid to remove any  $\text{NH}_3$  in the gas which would otherwise be absorbed by the picric acid and counted as naphthalene in the test. The second is charged with 100 cc. of 0.05 *N* picric acid; and the third with 50 cc. of the same soln. The fourth is left empty to catch any picric acid carried over in the gas. The standard picric acid soln. is prepared as follows: 35 g. of picric acid are dissolved in 600 cc. of boiling water, the hot soln. is poured into a Winchester qt. bottle containing 1800 cc. of cold water, and the contents are well shaken. When cold the soln. is filtered from sepd. picric acid, and 50 cc. of the filtered soln. are titrated with 0.1 *N* NaOH, using lacmoid or phenolphthalein as indicator. From the amt. of 0.1 *N* NaOH required to neutralize 50 cc. of the soln., the quantity of water necessary to make the soln. exactly 0.05 *N* is calcd. After the app. is charged, connected to the gas supply, and tested for tightness, the gas is passed through it at a rate not exceeding 1 cu. ft. per hr. up to about 10 cu. ft., the temp. of the gas and the barometer reading being noted at the beginning and end of the test as well as the vol. of gas passed, and the vol. corrected to 60° F. and 30 in. of Hg. The contents of the second picric acid bottle and any splashings in the last bottle are washed into the first picric acid bottle, this bottle being then closed by a tightly fitting rubber stopper fitted with a glass stopcock. The bottle is then evacuated by an air-pump until the naphthalene picrate ppt. rises to the surface of the liquid. The stopcock is then closed, the bottle placed in a water bath and heated and shaken until the naphthalene picrate

has dissolved. It is then cooled completely, occasionally being shaken to redissolve any naphthalene which may condense in the upper part of the bottle. Thus the whole of the naphthalene in the gas is converted into naphthalene picrate. When cold the contents of the bottle are poured into a 250 cc. measuring cylinder and the total vol. noted. The naphthalene picrate is then sepd. by filtering through a dry filter paper, rejecting the first few cc. which are weaker than the rest owing to picric acid being taken up by the filter paper. The remainder of the filtrate is then collected and 100 cc. of it titrated with 0.1 *N* NaOH, using the same indicator as before. The number of grains of naphthalene per 100 cu. ft. of gas may then be calcd. by the formula  $(V - V^1) \times 100 \times 0.1975 / \text{vol. of gas passed in}$  in which  $V$  = vol. of 0.1 *N* NaOH required to neutralize the vol. of 0.05 *N* picric acid taken, and  $V^1$  the vol. of 0.1 *N* NaOH required to neutralize the total vol. of picric acid soln. after heating and filtering. J. L. WILEY.

**Combining gas plants and coke ovens.** C. BERTHELOT. *Chimie & Ind.* 1, 471-80, 601-16(1918).—B. holds that the modern tendencies of the coking industry are toward the general use of the semi-direct process for  $(\text{NH}_4)_2\text{SO}_4$  manuf.; the fractionation of gas into 2 parts, one of 4500 cal. for city, industrial and domestic use, and the other of 3000-3500 cal. for heating the ovens; or, heating the ovens either by producer gas or blast furnace gas. The economic advantages of each of these tendencies are discussed, special stress being placed upon the conditions tending toward a combination of all the advantages of both gas plants and coke ovens into one installation. J. L. WILEY.

**Commercial "concentrated ammonia liquor" and its impurities.** HAROLD G. COLMAN AND E. W. YEOMAN. *Gas J.* 144, 567-8(1918); *Chem. Trade J.* 63, 421(1918).—Com. concd.  $\text{NH}_3$  (25%) manufd. largely for the prepn. of ammonium salts usually contains a considerable amt. of impurities of the crude liquor from which it is obtained.  $\text{H}_2\text{S}$  is almost always present, the amt. of which as specified by the govt. should not exceed 0.5%. It varies in the different samples from 0 to 3.1%.  $\text{CO}_2$  in many cases was absent and was usually present only in small amts. The liquor always contains phenols; in a few samples tested the figure ranged from 0.11 to 0.37 g. per 100 cc. Pyridine bases are always present, the av. being 0.26 g. per 100 cc.  $(\text{NH}_4)_2\text{S}_2\text{O}_8$  was found to vary from 0.08 to 0.25 g. per 100 cc., the quantity probably increasing during continued storage with access of air. No complaint was received, however, of any prejudicial effect due to presence of considerable amts. of this substance. With regard to cyanogen compds., the total amt. should not exceed 0.01 g. per 100 cc. for the manuf. of  $\text{NH}_4\text{NO}_3$ . It was found that the quantity greatly increases the longer the liquor stands, and at the end of 40 days was as high as 0.0334 g. per 100 cc. An interesting fact also is that the amt. found in gas-works liquor is considerably less than in coke-oven liquor, the resp. av. of 10 samples being 0.0245 and 0.1080 g. per 100 cc. This is attributed to the fact that the liquor on the gas-works is stored, during which time, by the action of O, the free cyanide is mostly converted into thiocyanate. To improve the quality of the concd. liquor, it is remarked that the purity of the liquor depends very largely upon the preheating process for removing the  $\text{CO}_2$  and  $\text{H}_2\text{S}$ . The cyanogen impurities can be affected by the addition of lime in distn. in sufficient quantity to ensure that all the  $\text{NH}_4$  salts are decomposed. A further plan is the passing of air along with the steam through the  $\text{NH}_3$  still; the total cyanogen, calcd. as  $\text{NH}_4\text{CNS}$ , is reduced at the end of a run of a week from 0.083 to 0.0304 g. per 100 cc., the HCN being converted into thiocyanate which passes away with the waste liquor. A further method is the treatment of the gases passing from the still, between that point and the reflux condenser, with a mixt. of  $\text{FeSO}_4$  and NaOH for the removal of the HCN. In some cases, a lime washer is already put in at this point to absorb any  $\text{H}_2\text{S}$  and  $\text{CO}_2$  which have not been removed in the preheater, while adding S as such to the lime tends

to retain the HCN as thiocyanate. Also in *J. Soc. Chem. Ind.* 37, 319-247(1918).

Fuel. D. MARKLE. U. S. 1,287,382, Dec. 10. A fuel mixt. is prepd. by mixing anthracite culm 100 with hard pitch 15-35 parts and heating the mixt. at a temp. sufficiently high (700° or above) to distill off the volatile constituents of the pitch without forming coke. The product may be used similarly to anthracite.

Producing gas. H. F. FREULER. U. S. 1,286,577, Dec. 3. Gas is produced by first electrically heating a mass of charcoal or other C fuel with a current of comparatively high voltage, reducing the voltage to regulate the temp. of the mass, and then injecting superheated steam into the mass to effect its decompn. with formation of CO and H.

Gas producers. F. W. CHAMIER, H. J. CRAIG and J. F. O. MOELLER. Brit. 120,051, Dec. 21, 1916. In the manuf. of power gas, the amt. of light oil obtained from the fuel is increased by treating the fuel in 2 successive stages, a low-temp. stage in which steam mixed with gas obtained from the second stage is passed through the fuel, and a high-temp. stage in which the final combustion of the fuel is effected by mixed steam and air. A suitable app. is specified.

Ammonium chloride. H. BAKER. Brit. 119,971, Jan. 22, 1918. Addition to 112,329 (*C. A.* 12, 992). The principal process is modified by evapg. the ammoniacal liquor to a desired concn., or to dryness during or after the liberation of the  $\text{NH}_3$ , and then treating the concd. soln., or the residue, after again dissolving in  $\text{H}_2\text{O}$ , with a metal compd. to remove the cyanides, the filtrate being then treated with  $\text{H}_2\text{S}$  or unpurified coal gas to remove excess of the precipitant and the purified soln. being evapd. to dryness as described in the parent specification. The  $\text{H}_2\text{S}$  may be obtained from the original gas liquor or from other  $\text{NH}_3$ -recovery processes.

The passing of petroleum. ANON. *Engineering* 106, 633-5(1918).—A review and discussion based mainly on a recent report by Gilbert and Pogue of the Division of Mineral Technology, U. S. Natl. Museum.  
F. W. SMITHER.

**Petroleum hydrology applied to Mid-Continent Field.** R. O. NEAL. *Bull. Am. Inst. Mining Eng.* 1919, 1-8.—This paper deals with the application of chem. analyses as a means of distinguishing between waters that encroach upon oil-bearing beds from sources in the same stratum and waters that reach the oil sands from horizons above. Tables of analytical data accompany the text. F. W. SMITHER.

**Transformer oil.** W. S. FLIGHT. *Electrician* 81, 636, 664, 686(1918).—Fixed oils often give trouble through the formation of sludge, while straight oils are freer from this defect. For transformers, sp. gr., viscosity, flash point and dielec. strength are important considerations. Moisture content is very important and in use care must be taken to prevent the oil from taking up moisture. Tests and methods of making them are described in some detail. Practical methods of preventing sludge are discussed. W. E. RUDER.

---

**Benzene superior to gasoline as auto fuel (ANON.) 21.**

---

**Distilling petroleum and the like.** M. J. TRIMBLE. *Holl.* 2,512, Aug. 1, 1918. The petroleum or the like is converted, in a special form of furnace, into a froth or vapor and liquid which is conducted into a vertical sepg. chamber of known type in which a thin layer of liquid flows down the walls suitably protected from cooling, the vapors formed escaping from various outlets and the chamber being heated from below by superheated steam.

**Purifying cracking agents obtained from mineral oil and sulfuric acid.** E. TWITCHELL. *Swed.* 43,923, Apr. 17, 1918. Cracking agents for fatty substances are boiled with alkali chloride soln. to salt out the alkali salts and compds. analogous to sulfaromatic fatty acids, whereupon the mineral oils are extd. by means of org. solvents.

**Cracking hydrocarbons.** SYNTHETIC HYDROCARBON Co. *Dan.* 23,052, Apr. 29, 1918. A ring-shaped chamber containing a perforated basket charged with metal turnings or the like is disposed in a furnace. The volatilized oils are cracked in contact with the metal.

---

## 23. CELLULOSE AND PAPER.

---

A. D. LITTLE.

**A paper tearing-resistance tester.** H. N. CASE. *J. Ind. Eng. Chem.* 11, 49-51 (1919).—A piece of paper  $2\frac{1}{2}$  in. long and 1 in. wide is slit lengthwise through the center to within  $\frac{1}{4}$  in. of one end. One of the slit ends is clamped in a fixed jaw and the other clamped to a small weighed bucket. Water is run into the bucket at a uniform rate until the partially slit paper tears through the  $\frac{1}{4}$  in. which remained uncut. The weight of the water in g. is the tearing resistance number. Tables are given showing the results of tests on several different grades of paper. R. B. ROG.

**Photographic paper technology.** ANON. *Paper* 23, No. 17(1919).—A description of the details of manufacturing photographic paper in France. R. B. ROG.

**Recovering alkali and other substances in cellulose production.** O. G. STAGE. *Can.* 187,316, Nov. 5, 1918. The strong black liquor is withdrawn from the cellulose digester and replaced with a weak liquor which washes the pulp; then both the strong and weak liquors are transferred to the furnace for use as fuel therein under heat and pressure without exposure to the air.

**Decomposing sulfite waste to extract organic and inorganic materials.** R. W. STREHLENER. *Norw.* 28,641, Mar. 11, 1918. In a modification of the process of

24,140, the waste is evapd. to 90% of its vol. before decomposing, so that a portion of the lime salt is pptd., and the combined  $\text{SO}_2$  is liberated, thereby facilitating pptn. and increasing the yield of dry product.

**Decomposing sulfite waste to extract organic and inorganic materials.** R. W. STREHLENERT. Norw. 28,655, Mar. 11, 1918. In a modification of the process of 24,140, the  $\text{SO}_2$  is converted into  $\text{SO}_3$  in the presence of small quantities of  $\text{H}_2\text{SO}_4$ .

**Decomposing sulfite cellulose waste lye.** R. W. STREHLENERT. Swed. 43,860, Apr. 3, 1918. The lye is heated in an autoclave under high pressure produced by the introduction of  $\text{SO}_3$  in such amt. that its partial pressure is greater than that of the steam pressure at the prevailing temp., whereby  $\text{H}_2\text{SO}_4$  required for the reaction is formed by oxidation of the  $\text{H}_2\text{SO}_3$ .

**Fiber for paper-making.** C. BRADLE. U. S. 1,286,502, Dec. 3. Fibrous material such as freshly cut stems of *Hedychium coronarium* are prepd. for the manuf. of unbleached paper by treatment with an alk. soln., e. g., a soln. of  $\text{NaOH}$ , at atm. pressure and at a temp. below the b. p., while simultaneously disintegrating the fibers by a beating operation. Organic substances are retained which are usually removed by a washing process and these substances serve to increase the weight of the product.

**Paper pulp.** J. WELLS. Brit. 120,086, Oct. 24, 1917. Material for the production of paper is obtained by heating previously dried and matured papyrus with lime water at temps. not substantially exceeding  $100^\circ$ . Either the dried and mature stalks may be treated, or the inner fiber and pith obtained from such stalks.

## 25. DYES AND TEXTILE CHEMISTRY.

L. A. OLNEY.

**Swiss dyes.** ANON. *Color Trade J.* 4, 4(1919).—Trade reports show that Switzerland is sending a considerable number of dyestuffs into the U. S., many of which are highly desirable colors not made in this country as yet. These dyes are apparently made in Switzerland, but there is the possibility that many of these dyes are made from intermediates produced in Germany.

L. A. OLNEY.

**The use of acid colors in the "dry dyeing" process.** M. FORT. *J. Soc. Dyers Colourists* 34, 226-7(1918).—The remarkable penetrating powers of carbolic acid and related phenols when applied to animal fibers, and the observation that many acid dyes can be dissolved in these solvents has led to a method of dry dyeing (i. e., dyeing from non-aqueous solvents) acid dyes on animal fibers. F. has satisfied himself that stable shades cannot be obtained with acid dyes on animal fibers when there is complete absence of water. Re-distd. phenols free from water do not readily dissolve acid dyes. Commercial cresol has been found to be the cheapest and most satisfactory phenolic solvent. Cresol alone or with 5% of water added is unsuitable, as it causes wool to curl and twist. Various non-aqueous solvents can be used for the main portion of the bath, along with smaller portions of the cresol soln. of the dye. To obtain fastness temp. should be raised to  $50^\circ$ . Data of 5 typical dye baths are given. The general procedure after dyeing is squeezing or hydro-extracting and rinsing with benzoline or naphtha to which 5% of cresol has been added. Cresol and volatile solvents should be recovered by distn. Use of a standing bath would require previous naphtha cleaning of all goods in order to keep the bath clean.

L. A. OLNEY.

**New process for the production of ungreenable aniline black.** ANON. *Color Trade J.* 4, 16-8(1919).—"The Calico Printers Association" and E. A. Forneaux have patented (Eng. pat. 115,278) a process for the production of aniline black on vegetable

fibers by the use of mixts. consisting of aniline, certain primary aromatic amines, HCl or HNO<sub>3</sub>, HCOOH, chlorates of alkali metals as oxidizing agents, and one or more catalysts, Cu or V salts alone or with an org. catalyst. The working of this process is described in minute detail for which the original paper should be consulted.

L. W. RIGGS.

**Davison's Textile Blue Book, United States and Canada.** Directory of Cotton and Woolen Mills and a Textile Supply Directory. 31st Ann. Ed. New York: Davison Publishing Co. 1471 pp. 55. For review see *J. Am. Soc. Mech. Eng.* 41, 84.

---

**Azo dyes of the pyrazolone series.** E. REBER. U. S. 1,286,411, Dec. 3. Aniline, diazotized and combined with 1-(5'-sulfo-3'-carboxy-2'-hydroxyphenyl)-3-methyl-5-pyrazolone in a soln. made alk. with Na<sub>2</sub>CO<sub>3</sub>, yields a yellow powder when the dye is salted out in the form of its Na salt, sol. in H<sub>2</sub>O but difficultly sol. in alc. even when heated. In an acid bath, this dye produces greenish yellow on wool, which is rendered fast by subsequent chromating. It may also be used to dye cotton with Cr mordants. By substituting *m*- or *p*-aminobenzoic acid for aniline as starting material, a similar dye is obtained. Other pyrazolone compds. such as the following, may also be substituted as starting materials: 1-(5'-chloro-3'-carboxy-2'-hydroxyphenyl)-3-methyl-5-pyrazolone, 1-(4'-carboxy-3'-hydroxyphenyl)-3-methyl-5-pyrazolone. Dianisidine, when substituted for aniline, produces a dye giving tile-red shades on wool and also giving a red on cotton.

**Nitrogenous vat dyes of the anthracene series.** CHEM. FABRIK GRIESHEIM ELEKTRON. Ger. 301,554, 1918. The yellow vat dye obtained by the action of concd. alc. alkali on pyrazoleanthrone forms alkali salts which react with the usual alkylating agents. The alkyl derivs. so formed are much deeper in color than the parent dye; *e. g.*, the benzyl compd. is scarlet, and the Et deriv., Bordeaux-red.

**Acyl derivatives of aminonaphthols and their sulfonic acids.** CHEM. FABRIK GRIESHEIM-ELEKTRON. Ger. 295,767 and 296,446, 1917. Aminonaphthols and their sulfonic acids are treated with 2-hydroxy-3-naphthoyl chloride or its acetyl deriv., giving naphthoylamino compds. which have a great affinity for cotton and silk. Thus, 2-amino-5-naphthol-7-sulfonic acid yields 2,2'-hydroxy-3'-naphthoylamino-5-naphthol-7-sulfonic acid, as an almost colorless, cryst. mass, which is fixed by cotton in an alk. soln. or by silk in HOAc soln., and may be coupled with diazonium salts on the fiber. 2,2'-Hydroxy-3'-naphthoylamino-8-naphthol-6-sulfonic acid, 1,2'-hydroxy-3'-naphthoylamino-8-naphthol-3,6-disulfonic acid, 1,2'-hydroxy-3'-naphthoylamino-7-naphthol, *m.* 198-200°, are pale gray, cryst. masses or powders.

**1,5-Dihydroxynaphthalenedicarboxylic acid.** FRANZ VON HEMMELMAYR. Ger. 296,035, 1917. 1,5-Dihydroxynaphthalenedicarboxylic acid is a yellow powder, *m.* about 300° (with decompn.), and forms colorless alkali salts, which exhibit blue fluorescence in H<sub>2</sub>O and may be easily "salted out." The acid and its salts combine with wool fibers, subsequent treatment with chromic acid or chromates giving very pure brown tones.

**Dyes suitable for pigment manufacture.** BADISCHE. Ger. 296,991, 1917. Diazotized 1-aminoanthraquinone is coupled with 1-benzoylamino-7-hydroxynaphthalene, or the substituted benzoylamino analogs, in the presence of Turkey-red oil, or such substances, with or without a substratum. The 8-benzoylamino- $\beta$ -naphthol,

m. 208-9°; 8-*o*-chlorobenzoylamino- $\beta$ -naphthol, m. 158-60°; 8-*p*-chlorobenzoylamino- $\beta$ -naphthol, m. 230-1°; 8-*o,p*-dichlorobenzoylamino- $\beta$ -naphthol, m. 186-7°; 8,2',6'-dichlorobenzoylamino- $\beta$ -naphthol, m. 227-8°; 8-*m*-nitrobenzoylamino- $\beta$ -naphthol, m. 255-60° (with decompn.).

**Dyes suitable for the manufacture of pigments.** BADISCHER. Ger. 297,414, 1917. Instead of 1-benzoylamino-7-hydroxynaphthalene or its derivs. containing substituents in the benzoyl residue, the corresponding *N*-alkyl compds. can be used. 1-Benzoylethylamino-7-hydroxynaphthalene, 1-benzoylmethylamino-7-hydroxynaphthalene, and 1,2'-chlorobenzoylethylamino-7-hydroxynaphthalene, m. 224-5°, 186-7°, and 232-3°, resp.

**Acid mono-azo dyes for wool.** BAYER & Co. Ger. 296,964, 1917. Good dyes which color wool yellow to bluish red or brown shades in acid baths are obtained by coupling pyrazolone-, methyl-ketol-,  $\alpha$ - or  $\beta$ -naphthol-, or 8-acylamino- $\alpha$ -naphthol-sulfonic acids with diazotized phenylenediamines of the type  $\text{NH}_2\text{R}'\text{NRR}'$ , where R = alkyl or aryl, R' = an aromatic acyl group, such as Bz or  $\text{MeO.C}_6\text{H}_4\text{CO}$ , and R' = the benzene nucleus or a homolog or substituted nucleus. The necessary bases are obtained by treating alkylated or arylated anilines with benzoyl chloride or substituted benzoyl chlorides, nitrating the products, and then reducing the nitro compds. Thus, ethylaniline, after benzylation, nitration, and reduction, yields benzoyl ethyl-*p*-phenylenediamine,  $\text{NH}_2\text{C}_6\text{H}_4\text{NEtBz}$ , m. 114°, and methylaniline gives benzoylmethyl-*p*-phenylenediamine, m. 143°. Benzoylethyl-*m*-toluidine yields benzoylethyltolylene-2,5-diamine, m. 140°; benzoylethyl-*p*-xylylene yields benzoylethyl-*p*-xylylene-2,5-

diamine,  $\text{NH}_2\text{C} \begin{array}{c} \text{CH:CMe} \\ \diagup \quad \diagdown \\ \text{CMe.CH} \end{array} \text{C.NEtBz}$ , m. 134°; benzoylmethyl-*o*-toluidine gives benzoylmethyltolylene-2,4-diamine, m. 167°; 2'-chlorobenzoylethylaniline gives 2'-chlorobenzoylethyl-*p*-phenylenediamine, m. 135°; and 4-nitrodiphenylamine yields benzoylphenyl-*p*-phenylenediamine, m. 178°.

**Triarylmethane dyes fast to light.** FARBWERKE VORM. M. L. & B. Ger. 295,495, 1917. Diarylindyl dyes, which contain an amino-, sulfo-, alkyloxy- or acyloxy group in place of the H atom in the *p*-position with regard to the methane C atom, are treated with primary aromatic amines. The following intermediate compds. are mentioned: *p*-methoxy-*p'*-dimethylaminobenzophenone, m. 133°, from *p*-methoxybenzanilide and dimethylaniline; *p*-hydroxy-*p'*-diethylaminobenzophenone, m. 188°, from *p*-amino-*p'*-diethylaminobenzophenone, which is obtained from the nitro compd., and this from *p*-nitrobenzanilide and diethylaniline; *p*-dimethylaminobenzophenone-*p'*-sulfonic acid, from the above amine by diazotization, treatment with  $\text{H}_2\text{SO}_4$  and Cu paste, and oxidation of the sulfinic acid with permanganate; *p*-amino-*p'*-dimethylamino-*o'*-methylbenzophenone, m. 151°, by the reduction of the product obtained from *p*-nitrobenzanilide and dimethyl-*m*-toluidine; *o*-benzyl-2-methylindole, b. 245° at 16 mm., by melting the phenylbenzylhydrazone of acetone with  $\text{ZnCl}_2$ .

**Developing colors produced on plant fibers with diazotizable dyes.** AKT. GGS. FÜR ANILIN-FABRIKATION. Ger. 303,409, 1917. The dye after diazotization in the usual way, is developed by treatment with an *N*-alkyl deriv. of chloro-*m*-phenylenediamine. 4-Chloro-*N'*-ethyl-1,3-phenylenediamine, colorless crystals, m. 53°, can be obtained by nitrating *p*-chloroacetoethylanilide, followed by removal of the acetyl radical and reduction of the remaining *p*-chloro-*m*-nitroethylaniline. 4-Chloro-*N'*-dimethyl-1,3-phenylenediamine, colorless leaflets, m. 80°, is obtainable by nitrating *o*- $\text{ClC}_6\text{H}_4\text{NMe}_2$  and reducing the resultant nitro compd.

**Vegetable dyestuff and tannic acid.** H. YOSHINAGA. Jap. 32,458, Mar. 29.

1918. The leaves and fruit of vegetables contg. dyestuff and tannic acid are expressed. The resulting liquor is filtered, boiled, and evapd. to dryness.

**Dyeing apparatus.** E. J. WILKINSON. U. S. 1,287,543, Dec. 10. The app. is especially adapted for dyeing piece goods.

**Lake containing titanic oxide.** L. E. BARTON and H. A. GARDNER. U. S. 1,286,916, Dec. 10. White pigments containing  $\text{TiO}_2$  are used as bases for the formation of lakes from dyes such as "paranitraniline reds" or "toluidine reds."

## 26. PAINTS, VARNISHES AND RESINS.

A. H. SABIN.

**Notes on the chemical analysis of red lead.** W. F. EDWARDS. Detroit. *Chem. Met. Eng.* 20, 35-7(1919).—Four well known methods for the detn. of the "true red lead" content of com. red lead are compared. The A. S. T. M. method and that of Lux, as described by Toch, were found to give good results except when the lead had been mixed with oil, even after very careful extn. of the oil. A modification of Mannhart's method in Holly's "Analysis of Paint and Varnish Products," was used, by making a stock soln. of 0.1 *N*  $\text{FeSO}_4(\text{NH}_4)_2\text{SO}_4 \cdot 6\text{H}_2\text{O}$  in  $\frac{1}{5}$  *N*  $\text{NH}_4\text{Cl}$ . Moisten 0.5 g. red lead and triturate with water, add 25 cc. stock soln. and 25 cc. concd.  $\text{HCl}$ . Heat and stir the mixt. till the red lead is decomposed and then titrate with 0.1 *N*  $\text{K}_2\text{Cr}_2\text{O}_7$  to det. the excess of  $\text{FeSO}_4(\text{NH}_4)_2\text{SO}_4 \cdot 6\text{H}_2\text{O}$ . Each cc. stock soln. consumed equals 0.03428 g. "true red lead." Wainwright's method as described in the 1910 and 1916 editions of "Stillman's Engineering Chemistry" was used, but on account of the necessity of boiling and cooling the solns. and as the titer of the  $\text{SnCl}_2$  must be found under identical conditions, the method was found objectionable. A modification is given which was found to give highly accurate results. Moisten 0.5 g. red lead with water and triturate till all is very finely divided (the condition for success), add 25 cc. 0.1 *N*  $\text{SnCl}_2$  and stir, add 25 cc. concd.  $\text{HCl}$  and stir till all but some white particles is dissolved, then titrate with 0.1 *N*  $\text{I}$ . The end reaction is sharp. The method also works well on lead peroxide, since it only requires double the quantity of  $\text{SnCl}_2$  and  $\text{HCl}$ .

J. E. CLARK.

**Constituents of resins.** II. Constituents of Sumatra gum benzoin. HANS LIEB AND ALOIS ZINKE. *Monatsh.* 39, 219-30(1918); *J. Chem. Soc.* 114, I, 502-3; cf. C. A. 13, 79.—Unlike Siamese gum benzoin, Sumatra gum benzoin dissolves completely in hot dil. aq.  $\text{NaOH}$ ; the resulting soln., on boiling, deposits the sodium salt of 1-benzoresinol, m. 339-41°,  $[\alpha]_D^{25} -12.88^\circ$ , probably of the compn.  $\text{C}_{20}\text{H}_{24}\text{O}_4$ . The mother liquors on the addition of a little  $\text{Et}_2\text{O}$  deposits the sodium salt of d-sumaresinol, needles with 4 mols.  $\text{H}_2\text{O}$ ,  $\text{C}_{20}\text{H}_{28}\text{O}_4 \cdot 4\text{H}_2\text{O}$ , m. 298-9°,  $[\alpha]_D^{25} 51.6^\circ$ . Methyl ether, crystals, m. 215-6°; ethyl ether, needles, m. 207-8°. It is isomeric with siarresinol. The benzoresinol of Ludy was probably a mixt. of d-sumaresinol with l-benzoresinol. C. J. WEST.

**Melting point of rosin.** T. L. CROSSLEY. *J. Ind. Eng. Chem.* 11, 52-3(1919).—Rosin has no definite m. p. and the results obtained, which vary with the method used, are tabulated for the capillary method and for the "column" method, using 3 different heights of a rosin column inside of a glass tube of small diameter with the bottom of the tube 1 inch below the surface of the  $\text{H}_2\text{O}$ . The most rapid detn. is by the "column" method, using a very thin film of rosin over the end of the tube, and these results are practically the same as those obtained by the capillary method. Cf. C. A. 6, 545.

F. A. WERTZ.

**Ester gums or artificial resin esters.** C. ELLIS AND L. RABINOVITZ. *J. Ind. Eng. Chem.* 8, 406-11(1916).—Rosin and other cheap, high-acid resins are too soft

for use in high-grade varnishes, and cause "livering" when used in grinding vehicles with certain pigments. E. and R. review the explanations given for this thickening effect. The neutralization of such resins improves them, but even rosin hardened by partial neutralization with  $\text{CaO}$ ,  $\text{ZnO}$ , etc., is not suitable for making grinding varnishes, and if too much of the oxides has been added the product becomes insol. in varnish solvents. To prep. esters of the soft resins, the softer constituents are removed by distn. or by leaching, and the residue then heated with equiv. wts. of glycerol, phenol, naphthol or carbohydrates at a high temp. with or without pressure. The patent literature on this subject is reviewed. Expts. on ester formation showed that a partial combination of rosin and glycerol took place when gases were bubbled through a mixt. of the two constituents at  $280\text{--}300^\circ$ , but the ester was usually soft and dark with an acid no. of 30 to 40, and considerable glycerol was volatilized. Mechanical stirring effected better esterification but the product was still dark in color. Various catalysts did not materially aid the process. The time, temp., and acid no. of the product from a number of runs are tabulated. Under ordinary conditions,  $\text{EtOH}$ ,  $\text{C}_4\text{H}_9\text{OH}$ , cresols,  $\text{C}_6\text{H}_5\text{NH}_2$ , and  $\alpha$ - and  $\beta$ -naphthylamines, sugar, starch and glucose did not react with rosin, nor did pressure in the presence of dehydrating agents or of I give beneficial results. A light-colored ester is demanded by varnish mfrs. and since esters darken on oxidation, some expts. were made using inert gases in the esterifying kettle. Dark esters cannot be bleached with bone black, fuller's earth,  $\text{SO}_2$ , etc. Detn. of acid no. was made on 1 g. of ester dissolved in 25 cc.  $\text{C}_6\text{H}_6$  or  $\text{Et}_2\text{O}$  and titrating with 0.1 *N* alc. KOH. What appears to be rosin acid anhydride is obtained by passing inert gases through rosin at  $300^\circ$ ; it differs from rosin in that when dissolved in  $\text{C}_6\text{H}_6$  or  $\text{Et}_2\text{O}$  and shaken with aq. alkali, it remains unaffected or reacts but slowly. This gives a rough method for detg. the anhydride content of rosin. The anhydride, however, even though it appears less reactive with alkali produces "livering" when mixed with basic pigments. A good rosin-glycerol ester should be light amber in color, contain no excess glycerol, dissolve readily in  $\text{C}_6\text{H}_6$  or turpentine to a soln. that remains clear, be practically insol. in 80%  $\text{EtOH}$ , and be practically unaffected by 10%  $\text{Na}_2\text{CO}_3$ . Copals are esterified with far more difficulty than rosin; they should first be cracked (heated). Damar, pontianak and congo esterify with glycerol to a certain extent. [Editor's note.—Through an error this paper was not abstracted back in 1916 when it appeared and the omission has just been discovered.] F. A. WERTZ.

Essential oil of *Pinus thumbergii* Parl. (SHINOZAKI) 17. Dyes suitable for the manufacture of pigments (Ger. pats. 296,991, 297,414) 25.

**Pigments.** A.-S. TITAN CO. Dan. 23,266, July 15, 1918. Substances contg. Ti-O compds. in amorphous form are heated until crystn. is effected.

**Titanium pigments.** A.-S. TITAN CO. Dan. 23,199, July 1, 1918. The Ti-O compds. are heated until the Ti compds. are converted into a fine cryst. form with increased covering power. Ti white is specified as suitable for the purpose.

**Painter's oil.** O. T. KRONSTAD. Norw. 28,678, Mar. 25, 1918. An oil for use in painting is composed of resin 35, whale oil 13, wood alc. or turpentine 46, litharge 3, and Cu fume 3.

## 27. FATS, FATTY OILS AND SOAPS.

H. SCHERUBEL.

The negative catalysis of the hydrogenation of oils. S. UENO. *Kogyō-Kwagaku-Zasshi* (*J. Chem. Ind. Japan*) 21, 898-939(1918).—The ratio number  $\gamma$  is defined as

$\gamma = (x - y)/x$ , where  $x$  and  $y$  are the I value after and before the hydrogenation of an oil. In the present investigation, the author compared the ratio numbers in the hydrogenation of soy bean and a fish oil by the Ni catalyzer with and without adding metallic soap, Ni salts, metallic oxides and other substances under the same exptl. conditions. The following substances retard the catalytic action of Ni: soaps of K, Na, Li, Mg, Ba, Be, Fe, Cr, Zn, Cd, Pb, Hg, Bi, Sn, Ur, Au;  $\text{Cu}(\text{OH})_2$ ,  $\text{Al}_2\text{SiO}_4$ ,  $(\text{NH}_4)_2\text{MoO}_4 \cdot \text{H}_2\text{O}$ ,  $\text{H}_2\text{BO}_3$ ,  $\text{As}_2\text{O}_3$ ; HCl, KOH; glycolic, lactic, hexahydroxystearic, oxalic, succinic, fumaric, malic, tartaric, citric acids; metallic Zn, Fe, Pb, Hg; S, Se, Te, P; protein, blood albumin, fibrin, gelatin, glycerol, lecithin, sucrose, glucose, mannitol, amylum; antipyrine, morphine, strychnine; KCN, amygdalin. S. KOMATSU.

The velocity of the hydrogenation of oils. S. UENO. *Kōgyō-Kwagaku-Zasshi* (J. Chem. Ind. Japan) 21, 749-62 (1918).—Soy bean, camellia and sardine oils were used in this study. The velocity of the hydrogenation of the oils with Ni catalyzer mixed with kieselguhr in the proportion of 1:3 at the definite temp. between 100-160°, was studied by determining from time to time the I value of the oils. The velocity of the reaction observed obeys the law of monomolecular reaction. S. KOMATSU.

The seed oil of *Amorpha fruticosa*. H. NAKATOGAWA. *Kōgyō-Kwagaku-Zasshi* (J. Chem. Ind.) 21, 781-2 (1918); cf. Shinozaki and Hoshino, C. A. 13, 361.—The seed oil of the plant grown in Manchuria is a brownish yellow substance,  $d_{20}^{20}$  0.9426,  $n_D^{20}$  1.4845, acid value 7.06, sapon. value 182.5, iodine value 133.71, butyrefractometer (20°) 80.8°. The yield is 8%. S. KOMATSU.

Neutralizing acid fats and oils. H. SCHLINCK. Dan. 23,298, July 29, 1918. Fatty acids are converted into esters with glycerol, glycol, etc., with the aid of a catalyzer such as naphtholsulfonic acid. To prevent increase of viscosity in the product, an indifferent substance in powder form is added. Cf. also 23,297, July 29, 1918, according to which the fats and oils are heated with glycol alone.

## 28. SUGAR, STARCH AND GUMS.

A. HUGH BRYAN.

Determination of water in molasses and other sugar-factory products by the distillation method. T. VAN DER LINDEN, M. KAUFFMAN AND F. LEISTRA. *Arch. Suikerind.* 25, 951-62 (1917); *Analyst* 43, 221.—The direct detn. of the water in cane molasses by distn. with xylene gives very satisfactory results, provided a certain rate of distn. is observed; if heating be prolonged, some decompn. of the product with the formation of water occurs. It is necessary to make a "meniscus correction" in measuring the vol. of water passing over (this amts. to 0.16 cc. under the conditions obtaining, xylene and not air being above), and also a correction for loss of water, either by volatilization or absorption by the liquid distd. (for the app. used this was found to be 0.3 cc.). Place 50 g. of the sample molasses or other product with 350 cc. of xylene in a Cu distn. flask connected with an upright condenser, the lower end of which discharges into a 250-cc. measuring cylinder graduated to  $\frac{1}{10}$  cc. So regulate the heat that about 100 cc. of distillate passes over in  $\frac{3}{4}$  of an hr.; after this accelerate the distn. so that in the fourth quarter of an hr. another 100 cc. distills over; remove the receiver immediately when 200 cc. have been collected. Other volatile immiscible liquids, benzene, toluene, kerosene, and mixts. of these, gave less satisfactory results.

E. H.

New Baumé scale for sugar solutions. FREDERICK J. BATES AND H. W. BEACHE. Bur. Standards, *Tech. Paper* No. 115, 1918.—There are three Baumé scales at present

in use in the U. S., all being related to sp. gr. by the equation  $d = m - (m/s)$ , where  $d$  is the Baumé degrees,  $s$  the sp. gr., and  $m$  a const. modulus. The new scale, or American scale, has a modulus of 145 and is based on a temp. of 60° F. The Gerlach scale has a modulus of 146.78 and a temp. of 17.5° C. The "old" or Holland scale has a modulus of 144. The latter two are used in the sugar industry. The American scale is used extensively in the acid industry. This new American Baumé scale has three features which should recommend it for use in the sugar industry: (1) It is based upon the sp. gr. values of Plato which are considered the most reliable. (2) It is based on 20° C, the most convenient and widely accepted temp. for sugar work. (3) It is based on the modulus 145, which has already been accepted by the Mfg. Chemists Association, by the Bureau of Standards, and all American mfrs. of hydrometers. An extensive table is given showing the relation between degrees Brix,  $d_{20}^{20}$ ,  $d_{20}^{20}$ , degrees Baumé (modulus 145). J. K. DALE.

The seeding method of graining sugar. H. E. ZITKOWSKI. *J. Ind. Eng. Chem.* 10, 992-4 (1918).—See C. A. 12, 1842. J. K. DALE.

Study of dextrin. M. YANO. *Kōgyō-Kwagaku-Zasshi (J. Chem. Ind.)* 21, 865-81 (1918).—Sweet-potato starch produced in Japan was employed in this study of the prepn. of dextrin. Hydrolysis by  $\text{HNO}_3$ , gave better results than by  $\text{HCl}$ ,  $\text{H}_2\text{SO}_4$  or  $\text{AcOH}$ . Make a paste of 10 parts of 0.5%  $\text{HNO}_3$  and 100 parts starch, dry at about 50° and then heat in a lacquered Zn pan at 150° for 1 hr. The dextrin thus obtained can be used as a substitute for gum arabic in 50-60% soln. S. KOMATSU.

Determination of aldehyde sugars (COLIN, LIEVIN) 7. Determination of reducing sugars (CLARK) 7.

Filtering sugar liquors. G. W. S. SIMPSON and R. F. LYLE. *Brit.* 120,055, July 24, 1917. Sugar liquors are purified prior to decolorization by charcoal by filtration through layers of sphagnum or leucobryum which has been dried, disintegrated, and cleaned by being boiled with alkali, such as  $\text{NaOH}$  or  $\text{Na}_2\text{CO}_3$ . The moss is packed between permeable retaining walls which may be covered by a cloth to retain coarse impurities. The cloth may be removed and washed without disturbing the moss. The moss may be cleaned by passing hot  $\text{H}_2\text{O}$  through the filter by or mixing the moss with  $\text{H}_2\text{O}$ . The filter may be in the form of a bed between horizontal partitions in a tank or may be in the form of a leaf filter or in the form of a rotary filter in which case the cloth covering is in the form of an endless band which travels through a washing trough and between  $\text{H}_2\text{O}$  sprays. Further details are specified.

## 29. LEATHER AND GLUE.

ALLEN ROGERS.

Leather, etc., substitutes (Brit. pat. 119,902) 30. Vegetable dyestuff and tannic acid (Jap. pat. 32,458) 25.

Substitute for leather. A. MEIER and H. RALL. U. S. 1,287,387, Dec. 10. A substitute for leather adapted for various purposes is formed by treating material such as albumins spread upon tissues first with a mineral tanning substance such as a Cr salt soln. and then with a soln. of  $\text{CH}_2\text{O}$ . Bacteria, yeast, glue or other sources of albumin may be employed.

Drying patent leather by ultraviolet rays. C. HEYL. *Swed.* 43,847, Apr. 3, 1918. Rays are employed which do not lead to the formation of ozone.

**Tanning.** C. BLANC. Brit. 120,049, Oct. 17, 1918. Chromic liquors for tanning are prepd. by reducing chromic acid, in an acid hydrolyzing medium, by cellulose or lignocellulose materials in a divided state. Three examples are given, in one of which the cellulose is mixed with the hydrolyzing acid such as  $H_2SO_4$  or  $HCl$  some hrs. before addition of the dichromate. Cellulose materials mentioned are sawdust; cotton, straw, and paper waste; spent tan; wood fibers; forage and cakes of inferior qualities; brewery residue; olive husks deprived of oil; and beet-root pulp.

### 30. RUBBER AND ALLIED SUBSTANCES.

JOHN B. TUTTLE.

**Influence of heavy tapping on the latex and rubber.** O. DE VRIES. *Med. Centraal Rubberstation* 1918, No. 9, 439-55.—Two series were run, on groups of 150 trees each, tapping with two left-hand cuts for  $\frac{1}{2}$  and  $\frac{3}{4}$  of the circumference. The principle changes were: the rubber content of the undiluted latex decreased from 45 to 17%; the sp. gr. rose from 0.966 to 0.998; tensile strength remained constant; rate of vulcanization decreased from 170 to 105 min.; viscosity decreased at first from 1.70 to 1.48, afterwards rising to 1.60. The trees tapped for  $\frac{3}{4}$  of their circumference showed more rapid changes, reaching the max. values before the other group. The continuation of these expts. was prevented by causes which permitted the trees to rest, such as seasonal decrease in latex; interruptions in tapping by rains; and shallow tapping by change in workmen.

JOHN B. TUTTLE.

**The nature of the vulcanization process.** G. VAN ITERSOM. Delft. *Intern. Assoc. for Rubber Cultivation in Netherland Indies Comm. of Netherland Govt. Inst. for Advising Rubber Trade and Ind.* Pt. 7, 239-61(1918).—I. bases his argument on the following established facts: (a) the process is additive; (b) the S is transferred into the combined state; (c) the "binding" is complete; (d) small quantities of S produce important changes in crude rubber; (e) the change in the properties of rubber during vulcanization is continuous; (f) the velocity of combining has a temp. coeff. situated between 2 and 3; (g) the velocity is strongly influenced by catalysts, acids retarding and alkalis in weak concn. accelerating; (i) first latex plantation rubbers, vulcanized under constant conditions produce mechanical properties which strongly correlate with the vulcanization coeff. (this does not follow with accelerated vulcanization); (j) continued mechanical treatment changes the mechanical properties but not the vulcanization coeff. After reviewing the work of Weber, Spence and Young, Hinrichsen and Kindscher, Skellon and Van Heurn, I. concludes that the amt. of S which can unite with rubber is greater than the 32% limit advocated by Weber and others. S on heating is transferred into other modifications, and the latter induce combination. I. assumes this combination to be colloidal, to which no objection can be raised on account of the continued combination at normal temp. if the change is understood to reach an equil. In this case, the modified S is constantly being eliminated by combination with the rubber. The assumption of colloidal combination would be sufficient to explain why small quantities of S produce such marked effects on the properties of rubber, as well as the continuity of the changes on continued vulcanization. I. then proposes two hypotheses to explain the known facts: (1) The colloidal S would unite to one complex with the rubber during vulcanization, this complex being insol. in the ordinary solvents for rubber. This change in S may be expressed as  $S_\lambda \rightleftharpoons S_\mu$ . As the  $S_\mu$  combines with rubber the medium in which the change from  $S_\lambda$  to  $S_\mu$  takes place changes and hence the increased velocity of the reaction through change in equil. The second hypothesis is that an active modification of S exists and that it combines chemically with a part of the rub-

ber to form a compd. insol. in the usual solvents for rubber, and this compd. unites colloiddally with the remainder of the rubber to form an insol. complex. The velocity of this reaction can thus be detd. by the rate of transformation of the original S into the active form, or by the rate of the chem. binding of the active S to the rubber. In this latter case, the chem. binding of the compd. with the remainder of the rubber would have to take place with a greater velocity than the chem. process. I. assumes therefore that catalysts act strongly on the reaction  $S_A \rightleftharpoons S_\mu$  to give a greater proportion of  $S_\mu$ . A rapid binding of S gives different mechanical properties than a slower reaction having an equal vulcanization coeff. This is probably due to the complex not having been exposed to heat for as long a period. Neither hypothesis limits the amt. of S which can combine with the rubber to 32%, and hence they do not conflict with the fact that percentages of combined S greater than 32% are obtained from mixts. rich in S which have been vulcanized for a long time. JOHN B. TUTTLE.

**The vulcanization of rubber at constant temperatures and by a series of increasing temperatures.** G. D. KRAITZ AND ARTHUR H. FLOWER. *J. Ind. Eng. Chem.* 11, 30-3(1919).—The authors show that at const. temp. S must be present in such an amt. that its active mass is not decreased during vulcanization to such an extent as to retard the reaction. For rubber-S mixts. containing less than 5% S better physical properties are obtained with a series of increasing temp. than with const. temp. They also claim that it is unwise to evaluate samples of vulcanized rubber solely upon their vulcanization coeff. JOHN B. TUTTLE.

**Aging of vulcanized plantation rubber.** HENRY P. STEVENS. *J. Soc. Chem. Ind.* 37, 305-67(1918).—A study of the change in vulcanization coeff., breaking strain and elongation of ordinary plantation sheet and unrolled sheet rubber, when subjected to normal aging over a period of 120 weeks. Coeffs. higher than 3.2 show increasingly rapid deterioration with increase in coeff. JOHN B. TUTTLE.

**Porosity of vulcanized rubber.** G. VAN ITERSOM. *Intern. Assoc. for Rubber Cultivation in Netherland Indies, Comm. of Netherland Govt. Inst. for Advising Rubber Trade and Ind.* Pt. 7, 223-37(1918).—Two types of porosity are described: Surface porosity is caused by condensation of water vapor on the surface during vulcanization. It may be obviated by wrapping to prevent contact, such as with wet clothes, tin foil, etc. Interior porosity is caused by lack of sufficient pressure to prevent expansion of air and water contained in rubber compd. or by too rapid release of steam pressure with under-vulcanized samples where the strength of the rubber is not sufficient to prevent permanent deformation. It is necessary to have sufficient counter pressure to resist air and water vapor expansion, and raise and lower temp. gradually, especially with under-vulcanized rubber goods. JOHN B. TUTTLE.

**Influence of heat on the inner qualities of rubber.** O. DE VRIES AND H. J. HELLENDOORN. *Med. Centraal Rubberstation* 1918, No. 10, 539-60.—Three series of tests were made to show the influence of heat: (a) on the latex; (b) on the wet coagulum; and (c) on dry rubber. Series "a" showed considerable increase in the rate of vulcanization (sometimes 100%), lower viscosity, with no change in tensile strength or slope of curve. Under series "b" soaking the freshly rolled crepe or sheet in hot water shows little effect at 40°, but at higher temp., especially at 60-70°, was very injurious. The rate of vulcanization, viscosity and tensile strength decreased. Heating the coagulum during rolling was injurious but not to the same extent as the soaking in hot water. Drying the rolled coagulum at higher temp. showed no effect at 40°, but at 60° the rate of vulcanization and viscosity decreased. Series "c" shows no change in the rate of vulcanization, but the viscosity and tensile strength are lower. The effect is quite marked at 85° or over, owing to oxidation, especially with free access to the air. JOHN B. TUTTLE.

**Influence of rustiness on the inner qualities of sheet rubber.** O. DE VRIES AND H. J. HELLENDORF. *Med. Centraal Rubberstation* 1918, No. 10, 529-38.—Hellen-dorf has shown (to be published later) that rustiness is caused by aerobic organisms presumably related to those which form dextrin and similar substances from sugars. This film is a jelly-like substance produced from the serum by the action of these organisms. Rapid surface drying is said to be the best means of preventing rustiness. The authors show that rustiness causes no appreciable change in tensile strength, but hastens vulcanization and increases the viscosity.

JOHN B. TUTTLE.

**The viscosity of plantation rubber, its relation to the properties after vulcanization, and its significance in rubber testing.** O. DE VRIES. *Med. Centraal Rubberstation* 1918, No. 9, 456-86.—de Vries expresses his results as the index of viscosity, *i. e.*, the logarithm of relative viscosity for a soln. of 1 g. rubber in 100 cc. benzene. He claims that there is no relation between viscosity and tensile strength. Several factors cause a decrease in both: (1) heat, (2) salts and alum, (3) organisms attacking the rubber [a separate article by de Vries and Hellen-dorf (cf. preceding abstr.) states that "rustiness" causes no change in tensile strength although influencing the viscosity.—ABSTR.]; (4) rubber from young trees. Many factors cause the viscosity and rate of vulcanization to change at the same time; basic substances increasing both and acid substances the reverse. de Vries was unable to find any relationship between viscosity and the slope (*i. e.*, the resistance to stretching, or the elongation curve). Three groups of factors are recognized. (1) Those changing the state of aggregation. The viscosity is affected but the properties after vulcanization are not. (2) Chemicals used in the prepn. of the crude rubber change the viscosity and rate of cure but do not affect the tensile strength. (3) Factors which cause decompn. or oxidation lower the viscosity and tensile strength.

JOHN B. TUTTLE.

**The determination of free carbon in rubber goods.** A. H. SMITH AND S. W. EPSTEIN. *J. Ind. Eng. Chem.* 11, 33-6(1919).—This method consists essentially in removing by soln. such constituents as may be decomposed or volatilized by heat, using concd.  $\text{HNO}_3$  to form acetone-sol. deriv. of rubber, and igniting the residue. The loss on ignition is assumed to be free C; it is usually about 105% of the amt. present. Corrected by this factor the results are sufficiently accurate for com. work.

JOHN B. TUTTLE.

**Apparatus for vulcanizing rubber articles.** W. C. MERRILL. U. S. 1,287,071, Dec. 10.

**Leather, etc., substitutes.** J. L. WATKINS. Brit. 119,902, Oct. 16, 1917. In the manuf. of rubber substitutes of the kind containing scrap and new rubber, scrap leather, and a cotton or other vegetable fiber, together with kapok, the leather and old rubber are pulverized with the new rubber, asbestos is added in powdered or fibrous form, and the whole is mixed with oil and kapok fiber. There may also be added either or both a jute fiber and a silk fiber and a metallic oxide, as well as a vulcanizing agent such as NaOH or S. The dough-like mixt. is rolled into sheets or bars and vulcanized; it may include a coloring agent, and also for the purpose of making a heavy material, crushed slate or cement. Proportions are given for a typical mixt.

## I. APPARATUS.

L. C. JONES.

**Simplified gas analyses.** J. J. R. MACLEOD. Toronto. *J. Lab. Clin. Med.* 4, 69-72(1918); cf. *C. A.* 12, 2328.—For the purposes of teaching, the usual types of gas buret are unsuitable because of the care that has to be given them to prevent "freezing" of the stopcocks. An app. can be constructed by using screw clips in place of stopcocks, provided some means be taken to adjust the gas pressure in the buret after the screw clips have been tightened. This is accomplished by a device known as a pressure adjuster which is described and shown in diagram. G. T. CALDWELL.

**Carbon dioxide recording apparatus.** NAITO. *Engineering* 106, 515(1918).—"The author explains that the principle of  $\text{CO}_2$  recording is to relate temp. in a furnace with the ratio of  $\text{CO}_2$  in the flue to vol. of air supplied; excess of air obviously lowers the temp. and hence as long as sufficient air is available, the higher the temp. the higher the % of  $\text{CO}_2$ . He criticizes existing app., and proposes one as shown in the fig.  $P$  is a  $\text{H}_2\text{O}$ -jet pump supplied with acidulated  $\text{H}_2\text{O}$ ; it sucks the gas from the flue and passes it into the reservoir  $C$ , where the gas collects at the top. Between  $C$  and the absorbing bottle  $E$  is a valve  $D$ . The absorbing element, placed in the lower division of  $E$ , consists of an alkali soln., and into this soln.  $B$ , through its connection with the valve  $D$ , descends when  $D$  is opened.  $B$  is built up of thin strips of material non-corrosive to alkali, bound together at top and bottom. With valve open, and  $B$  in its lowest position, immersed in the alkali soln., this soln. is shut off from the gas, the bottle being closed by the upper rim of  $B$ . In this position the gas passes through  $E$  without contact with the alkali and lifts the holder  $H$  until excess bubbles out at  $F$ ; the rise of  $H$  measures quantity. Valve  $D$  is then closed,  $B$  being raised simultaneously so as to open the bottle of alkali soln.; the latter absorbs the  $\text{CO}_2$ ,  $H$  falling by the amt. of the absorption. The ratio of the fall of  $H$  to its original height gives the %."

A convenient and efficient digestion apparatus for the determination of crude fiber. HOWELL D. SPEARS. *J. Ind. Eng. Chem.* 11, 140-1(1919); illus. E. J. C.

An efficient laboratory funnel for filtering neutral liquids, especially the volatile organic solvents. T. B. ALDRICH. *J. Ind. Eng. Chem.* 11, 139-40(1919); illus. E. J. C.

A drying apparatus. C. J. VAN NIEUWENBURG. *Chem. Weekblad* 15, 1548-9 (1918).—A cast iron receptacle is made to receive a 250-cc. beaker, which rests on its flange in the opening, the inside diam. of which is not more than 2 mm. greater than the outside diam. of the beaker. The receptacle has 2 side arms, which are heated with Teclu burners. The evapn. proceeds rapidly, and the loss by spattering even from the open beaker is within the limits of exptl. error. JULIAN F. SMITH.

Washing in filter presses. D. R. SPERRY. *Chem. Met. Eng.* 19, 680-2(1918); cf. *C. A.* 12, 1847.—An elementary description of chamber presses equipped for "through" or "thorough" washing. W. L. BADGER.

Material conveyors for furnaces. T. B. CRAM. *Can.* 188,373, Jan. 21, 1919. Structure.

## 2. GENERAL AND PHYSICAL CHEMISTRY.

WILLIAM D. HARKINS AND E. B. MILLARD.

Relationships in chemistry. J. W. BECKMAN. *J. Ind. Eng. Chem.* 11, 145-6 (1919).—The relationships discussed in this address have to do with the attitude towards each other of the so-called inside chemist or university man and the outside chemist or industrial man. E. J. C.

The Research Division, Chemical Warfare Service, U. S. A. GEO. A. BURRELL. *J. Ind. Eng. Chem.* 11, 93-104(1919).—An interesting story of the organization, personnel and work of this division. E. J. C.

The training of the chemist. EDWARD ELLERY. *J. Ind. Eng. Chem.* 11, 166-7 (1919); cf. *Church, C. A.* 13, 165. E. J. C.

Is high-school chemistry a vocational subject? HANOR A. WEBB. *School and Society* 8, 672-5(1918); cf. *C. A.* 13, 87. E. H.

Outline of a scheme of laboratory design. ANON. *Chem. Trade J.* 64, 5(1919).—A plan for an industrial lab. is discussed. E. H.

India and the chemist. ANON. *Chem. Trade J.* 64, 3-4(1919). E. H.

The Grassell medal. *J. Ind. Eng. Chem.* 11, 162(1919).—The Grasselli Chemical Co., of Cleveland, O., has announced its intention to found a medal to be awarded by the New York Section of the Soc. of Chem. Ind. The rules for the award are given. E. J. C.

The distribution of errors in the determination of atomic weights. P. A. GUYE AND T. RENARD. *Arch. sci. phys. nat.* 44, 402-3(1918).—This note is a brief discussion of the disagreement between errors of the detns. of at. wts. on the av. and the laws of calcg. probabilities. The large errors are numerous as compared with smaller ones even in the three methods of detn. employed (cf. *C. A.* 12, 2467). The calcn. of the probable error seems to have no real significance since the error may be abs. with reference to the av., depending upon the measure of precision; algebraic, depending upon

the dissymmetry of observations; or quadratic, depending upon their dispersion. It is an open question, therefore, whether the no. of detns. has been too small to permit application of probability laws, or whether these detns. conceal a cause of error which has escaped investigators.

G. L. CLARK.

**Density, compressibility and atomic weight of argon.** A. LEDUC. *Compt. rend.* 167, 70-1 (1918).—Argon which contd. about 5% impurities (chiefly O and N) was prepd. by fractional distns. over coconut charcoal. The gas was then allowed to flow many times from one flask to another through a red-hot tube containing shavings of Ca and CuO to remove the O and N. The CuO serves to destroy hydrocarbons, etc., evolved by the Ca. Finally the gas was passed over KOH and P<sub>2</sub>O<sub>5</sub> and these operations were repeated until no change in density resulted from them. Detd. by the method described in connection with the at. wt. of Ne (C. A. 8, 2831), the limiting d. was 1.3787; the difference between this and the 1.379 of Ramsay is not guaranteed. The mean coeff. of deviation from Mariott's law at 14° is  $10.2 \times 10^{-8}$  per cm. of Hg. If A is to be included in L.'s series of normal gases this coeff. should be  $8.5 \times 10^{-8}$ , or in applying his formulas the crit. pressure should be taken as 40 atm. in place of 48 atm. The mol. vol. of A relative to that of a perfect gas is 0.9990; the same ratio for O is 0.9992. Hence the at. wt. of A is  $32 \times (9990/9992) (1.3787/1.1053) = 39.91$ . There is perhaps some uncertainty as to the second place of decimals. (Details of the expts., individual detns. from which means were derived, etc., are not given.—ABSTR.)

E. B. MILLARD.

**Melting points of chemical elements, and other standard temperatures.** Bur. of Standards, *Circ.* 35, 3rd edition, revized July 15, 1918.—The other standard temps. given are the boiling points of O (−183.0°), H<sub>2</sub>O, naphthalene (217.96°), benzophenone (305.9°) and S (444.6°), the sublimation point of CO<sub>2</sub> (−78.5°), the point of transformation of Na<sub>2</sub>SO<sub>4</sub>·10H<sub>2</sub>O into Na<sub>2</sub>SO<sub>4</sub> (32.384°), the eutectic freezing point of 3Ag<sub>2</sub>Cu (779°) and the f. p. of NaCl (801°).

E. J. C.

**Simple device for illustrating molecular motion.** E. R. STOKKLE. *Science* 48, 474-6 (1918).—If finely powdered glass or some similar substance is placed on the surface of Hg in an evacuated glass tube, and the Hg then slowly heated, the particles of glass will display motions corresponding to those of the Hg mols.

F. C. HOYT.

**The determination of the compressibility of solids at high pressures.** LEASON H. ADAMS, ERSKINE D. WILLIAMSON AND JOHN JOHNSTON. *Geophysical Lab., Wash., D. C. J. Am. Chem. Soc.* 41, 12-42 (1919).—A method is described for measuring the compressibility of solids under hydrostatic pressure, and results are presented for 16 materials at pressures up to 12000 megabars. The  $P-\Delta v$  graph for Au, Cu, brass, Ag, Al, and calcite, like that of steel, is linear; but for Zn, Sn, Cd, Pb, Sn-Bi alloy, quartz, Bi and NaCl, the graph shows an appreciable curvature, thus indicating a decrease of compressibility with increasing pressure. A comparison was made of the compressibility of two alloys with that of their components. In the case of a simple mixt., such as the Sn-Bi alloy, the measurements indicate that the compressibility of mixts. whose other properties, such as sp. vol., elec. cond., and sp. heat, are approx. linear functions of the compn., is related in the same simple way to the compressibilities of the separate components. However, the compressibility of alloys of the class to which brass belongs is much lower than the sum of the individual compressibilities.

R. H. LOMBARD.

**Compressibility of aqueous solutions, especially of urethan, and the polymerization of water.** THEODORE W. RICHARDS AND SVEN PALITZSCH. *Harvard Univ. J. Am. Chem. Soc.* 41, 59-69 (1919).—The compressibilities of aq. solns. of urethan were measured at 20.00° over a pressure range from 100 to 300 megabars. A minimum

occurs with the soln. containing 24 g. urethan to 100 g.  $H_2O$ . Surface tension, viscosity, and specific vol. are also measured, but display no minimum. These results are shown to be in accord with the theory which regards  $H_2O$  as a mixt. of mono-, di- and tri-hydrol.

F. C. HOYT.

The miscibility of phenol and aqueous solutions of alkalis. RENÉ DUBRISAY, TRIPIER AND TOQUET. *Compt. rend.* 167, 1036-8(1918).—To det. the soly. of phenol, a known amt. of phenol is mixed with a definite quantity of an aq. soln. of NaOH of known strength and the mixt. heated till complete soln. has taken place. The soln. is then allowed to cool with stirring and the temp. at which turbidity appears is recorded. In the same way, the soly. of phenol in aq. soln. of various bases, acids, and salts was detd. The results are exactly what might be predicted. When the phenol is dissolved in water, the temp. at which the turbidity appears is higher than when the phenol is dissolved in aq. NaOH or alk. earth hydroxides and is lower than when it is dissolved in aq. NaCl,  $Na_2SO_4$ , HCl,  $H_2SO_4$  or  $Na_2CO_3$ .

ROGER ADAMS.

Chemical reactions at low pressures. IV. The clean-up of nitrogen by a heated molybdenum filament. IRVING LANGMUIR. *J. Am. Chem. Soc.* 41, 167-94(1919).—The possibility that a Mo filament heated in a fairly high vacuum (0.03 mm. and less) to a temp. at which vaporization occurs (2000-2400 K.) may clean-up  $N_2$  more efficiently than W, since it evaps. more rapidly, is not realized exptly. The rate of evapn. was found to be the same as in vacuum; hence  $N_2$  does not attack the Mo filaments. Denoting by  $\epsilon$  the ratio of the number of mols. of  $N_2$  cleaned up to the number of atoms of Mo evapg. in the same time, the following exptl. facts are outstanding:  $\epsilon$  is always less than 1, is independent of pressure and decreases as bulb and filament temp. is raised. The highest values were about 0.4 and the lowest 0.01. There is no clean-up in the presence of any  $H_2O$  vapor, as is true with CO instead of  $N_2$ , where  $\epsilon$  is unity. The author presents a theory of the mechanism of the clean-up from the observed facts to the effect that Mo atoms and  $N_2$  mols. combine to form at least 2 products: the very stable NMoN from the colliding mols. of low relative translational velocity and high rotational velocity of the  $N_2$  mols.; and the secondary compd.  $Mo:N_2$  which decomposes on striking the bulb because of the greater attraction of the Mo atoms for each other. This theory is used to account for the nature of the metallic deposit, its spongy character, the loss of only part of the  $N_2$  from it, which is not entirely reabsorbed, the absorption of  $N_2$  but not  $H_2$  when cooled with liquid air, complete chem. combination with  $N_2$  at  $270^\circ$ , and extreme activity such that  $H_2O$  is decomposed at room temp.

G. L. CLARK.

Relations between distribution ratio, temperature, and concentration in the system: water, ether, succinic acid. GEO. S. FORBES AND ALBERT S. COOLIDGE. *J. Am. Chem. Soc.* 41, 150-67(1919).—This paper records an exhaustive study of the extent and causes of deviation from a constant usually assumed of the ratio of distribution of succinic acid between  $H_2O$  and  $Et_2O$ , with a view to deriving equations to show the actual behavior. The mutual soly. of the solvents, the change in compn. of each with concn. of dissolved acid, the electrolytic dissociation of acid in the  $H_2O$  layer, and very complex variations with temp. are recognized as the causes of the value of the ratio. Measurements are therefore given of the soly. of  $Et_2O$ ,  $H_2O$  and succinic acid in 2 and 3 component systems between  $15^\circ$  and  $25^\circ$ , and of the actual distribution ratio of the acid between the 2 solvents at various concns. and temps. The complete differential of the ratio with respect to temp. is derived, using a solid figure, as a function of 8 partials, 4 of temp. and 4 of soly., from the effects of temp. upon solubilities involved, with const. solvent compn., and from sep. effects of changing solvent at const. temp. such that  $dR/dT = 0.0257$ , agreeing closely with exptl. values.

With respect to variations with increasing concn. of dissolved acid, the ratio when calcd. upon a basis of unchanging solvents increases sharply even after correcting for dissociation of acid and association of  $H_2O$ . By means of the Rothmund mutual soly. equation it is shown to be probable that the av. state of association of  $H_2O$  dissolved in  $Et_2O$  is somewhat less than 2.

G. L. CLARK.

Heterogenous equilibria between aqueous and metallic solutions; the interaction of mixed salt solutions and liquid amalgams. V. A study of the ionization relations of potassium and strontium chlorides in mixtures. G. MCP. SMITH AND E. A. REES. Univ. Ill. *J. Am. Chem. Soc.* 40, 1802-47(1918).—The ionization relations of  $KCl$  and  $SrCl_2$  in soln. were studied by detg. the equil. distribution of  $K$  and  $Sr$  between mixed solns. of  $KCl$  and  $SrCl_2$ , and mixed dil. liquid amalgams containing  $K$  and  $Sr$ . In equiv. mixts. of  $KCl$  and  $SrCl_2$  the  $Sr^{++}$  fraction decreases, while the  $K^+$  fraction correspondingly increases, with increasing total salt concn. The ion fractions are not directly proportional to the mol. fractions of the salts. This fact is in accordance with Werner's conceptions concerning the formation and dissociation of higher order compds. The value of the "equil. expression,"  $C_c = (SrHg)(KH_2O)^2/(KHg)^2(SrH_2O)$ , increases directly with the concn. of the amalgam up to about 0.3 milli-equiv. of metal per 10 g. Hg. From a study of the interaction equil. between the mixed solns. and amalgams, between  $15^\circ$  and  $40^\circ$ , the heats of different interactions were calcd. by the van't Hoff equation. The interaction heat increases gradually with decreasing total salt concn. In the case of both  $Sr$  and  $K$ , the free atomic concn. in the dil. equil. amalgam is directly proportional to the hydrargyride concn. in the sense of the equation  $Me + xHg = MeHg_x$ ; and the mass action expression  $(Me)/(MeHg_x) = K_M$ , holds for  $K$  and  $Sr$  hydrargyrides in the presence of one another at total concns. up to 2 milli-equiv. per 100 g. Hg. In mixed amalgams of  $K$  and  $Sr$ , when in equil. with a mixed soln. of fixed concn., the free atom fraction of  $Sr$  decreases, while that of  $K$  increases in proportion to the total concn. of the amalgam. This shows that the degree of dissociation of the  $Sr$  hydrargyride is much less than that of the  $K$  hydrargyride.

R. H. LOMBARD.

Affinity studies. XII. A thermodynamic relation between the mixing affinities in partly saturated solutions and its application for the determination of affinities. J. N. BRØNSTED. Kjøbenhavn, Denmark. *Kgl. Danske Videnskabernes Selskab. Matematisk-fysiske Meddelelser*. I, No. 5, 39 pp.(1918).—There is found in this paper a relation between the potentials of 2 components in a mixt. containing more than 2 components and in which the potentials of the other components are kept const., e. g., by having the solns. in question always satd. in these components. This relation is expressed by the equations  $x(dA/dx) + (1-x)(dA_1/dx) = 0$ , or  $n_1dA_1 + n_2dA_2 = 0$ , where  $A$  and  $A_1$  mean the differential, mol. mixing affinity of the components  $K$  and  $K_1$  and  $n_1, n_2$  the number of mol. in the mixt. These expressions have consequently the same form when the 2 components are present in a binary mixt. For the math. derivation of the formula see the original paper. The calcn. of the affinity of the reaction  $\alpha CaCl_2 \cdot 4H_2O$  to  $\beta CaCl_2 \cdot 4H_2O$  and the formation of carnallite and schönite from the cryst. compds. of these double salts is given. There is also described an exptl. method by which the vapor pressure and the concn. of the soln. can be detd. at the same time, and also by which can be found the points at which satn. occurs of 1 or 2 components. By means of this method the necessary data are found for the reaction  $KCl + NaClO_3 \rightleftharpoons KClO_3 + NaCl$  and  $KCl + NaNO_3 \rightleftharpoons KNO_3 + NaCl$  and the affinities are calcd. from the formula. The values, resp. 2020 cal. and 740 cal., check very well with those obtained from earlier measurements (C. A. 6, 1697) done in electrometric way, resp., 2070 cal. and 720 cal. This verifies the formula derived.

H. DEDICHEN.

**Silicate specific heats, 2nd series.** WALTER P. WHITE. Geophys. Lab., Washington. *Am. J. Sci.* 47, 1-43(1919).—The sp. heats of 19 substances, silica and silicates, cryst. and amorphous (glass), were detd. for upper temps. from 100° to 1400° (in some cases) by dropping from elec. or steam heaters into a water calorimeter at room temp., with methods that represented some improvement over those of C. A. 3, 2899; 5, 419, 420, 808. (a) Lack of uniformity of furnace temp. was regarded as the most serious source of error, and was quite satisfactorily overcome by using (1) a long furnace cavity (20 cm.  $\times$  4.8 cm. diam.), (2) Pt-faced shielding partitions, (3) winding concd. at the end, (4) a very fine thermoelement, inserted into the charge. Tests indicated at most only 0.2° difference between thermoelement and mean temp. of a charge 4.2  $\times$  6.0 cm. at 1100°, and several times this difference would not have been important. (b) The precision of the calorimeter was well in excess of requirements, thanks to a sensitive 24-couple thermoelement (C. A. 8, 3731, 3740), which nevertheless needed less care and precaution in use than less sensitive thermometers of most other kinds would have done. (c) Errors in dropping the hissing hot charges into the calorimeter water it was sought to eliminate by using as a tare the total effect on dropping the container alone, but the accidental irregularities, though seldom over 1 per mille, were disappointingly large, and by far the most prominent in the work. An unusual number of schemes were used for detecting "concealed," i. e., systematic or partly systematic errors, nearly always with negative results, and the conclusion is reached that in the original data, sp. heats over intervals from 0° and upward, "errors greater than 3 per mille are probably exceptional." Interval sp. heats alone are unsatisfactory; for getting from series of interval heats values of true sp. heat, two very accurate methods are given, which, however depend on having the original data evenly spaced along the temp. scale. The true heats obtained in this way necessarily have larger errors than the data from which they are derived. The values given in C. A. 3, 2899, do not differ over 5 per mille from the later ones. For some other substances and also for microcline, given as "orthoclase" in 1909, the mean atomic heats at different temps. are:

|                                     | 100°. | 300°. | 500°. | 700°. | 900°. | 1100°. |
|-------------------------------------|-------|-------|-------|-------|-------|--------|
| Silica glass.....                   | 4.05  | 4.95  | 5.35  | 5.58  | 5.75  | ....   |
| Quartz.....                         | 4.1   | 5.1   | 5.9   | 5.46  | 5.66  | ....   |
| Cristobalite.....                   | ....  | ....  | ....  | 5.55  | 5.67  | 5.77   |
| MgSiO <sub>3</sub> , amphibole..... | 4.42  | 5.26  | 5.62  | 5.87  | 6.04  | ....   |
| Albite.....                         | 4.28  | 5.10  | 5.46  | 5.71  | 5.91  | ....   |
| Microcline.....                     | 4.27  | 5.09  | 5.47  | 5.72  | 5.86  | ....   |
| Microcline vitrified.....           | 4.38  | 5.22  | 5.61  | 5.85  | 6.11  | ....   |
| Quartz at 550° is 6.3               |       |       |       |       |       |        |

Sp. heats can be obtained from these through division by: 20.1 for SiO<sub>2</sub>; 20.12 for MgSiO<sub>3</sub>; 20.33 for albite; 21.23 for microcline. Conclusions: (1) The low values of these at. heats, and their rapid increase, are a phenomenon mainly to be associated with the combined O the substances contain. (2) The heats of silica glass and cristobalite, compared with the latest formulas for at. heat, indicate that at. heats tend generally to increase at high temp. as they have been known to do more noticeably for metals. (3) The sp. heat on the amorphous form (glass) is nearly always from a few per mille to a few % above that of the crystal. (4) The at. heat of quartz for 300° below its inversion at 575°, though high, is not nearly high enough to account for the mechanical work done against cohesion in the anomalous expansion which takes place; the various phenomena over this extended temperature region thus have nearly all the characters of the changes of state which usually take place (when equil. is secured) at single temps. Moreover, the quartz inversion at 575° differs from most others, apparently, in that it does not consist in the growth of new crystals from

new nuclei, but in a springing of the whole crystal. Probably the same inversion occurs in a modified form in cristobalite also. Since quartz and cristobalite may change into one another by a very sluggish inversion we have two kinds of inversion, of independent and very different character, in the same compd. as also inferred by Fennel from the difference in promptness and amt. of change. Since Smits had held that the phenomena of cristobalite strongly confirmed the mix-crystal theory of allotropy (C. A. 5, 1861), it is pointed out that the difference in the character of the 2 kinds of inversion strongly discredits the application of the theory, which referred both to the same mechanism or cause. Other arguments for the theory are examd. and rejected. The peculiar inversion of  $\text{HgI}_2$  claimed by Smits, and apparently the best confirmation of the theory, H. E. Merwin and White, working together, were quite unable to repeat.

W. P. WHITE.

Specific heat determination at high temperatures. WALTER P. WHITE. Geophys. Lab., Washington. *Am. J. Sci.* 47, 44-59(1919).—Treats of exptl. methods and app. of previous paper (cf. preceding abstr.). Studies of behavior of calorimeter on exposure to air or to hot furnaces are briefly given. Time for reaching equil. in calorimeter or furnace was found greatly and often unaccountably different with different substances. The differences if neglected may cause serious error. The error in dropping and methods of diminishing it are discussed.

W. P. WHITE.

The thermal magnetic phenomenon. PIERRE WEISS AND AUGUSTE PICCARD. *Arch. sci. phys. nat.* 45, 329-35(1918).—See C. A. 12, 1144.

O. A. RANDOLPH.

Thomson effect in bismuth-tin alloys. A. E. CASWELL. *Phys. Rev.* 12, 231-7 (1918).—On the same metal specimens as were employed in the measurement of Peltier e. m. f. and thermo-elec. power (cf. C. A. 6, 452; 10, 997) the Thomson effect is detd. by a new compensation method between 2 bars of the same metal. With 2 bars of homogeneous material and uniform cross-section, a simple formula can be used, since, except in the case of those substances having abnormally high Thomson effects, the resistance of unit lengths of the bars and temp. gradients in them will be the same.  $\sigma = (2I - i)r / (2\pi I - i)t$ , where  $\sigma$  = abs. Thomson effect,  $I$  = current through generator,  $i$  = current through shunt resistance,  $r$  = resistance of bar,  $t$  = temp. gradient in degrees per unit length of bar, and  $\pi$  = fraction of proper compensation actually effected. The results obtained show a remarkable increase in the Thomson effect when very small amts. of Sn are added to pure Bi: e. g., 58 microvolts per degree C. for pure Bi and 676 for 1% Sn alloy. Beyond about 2% of Sn the value of the Thomson effect decreases.

G. L. CLARK.

Some problems of evaporation. H. JEFFREYS. *Phil. Mag.* 35, 270-80(1918).—A mathematical treatment of the problem of evapn. from which it is shown that when evapn. takes place in still air, the rate is proportional to the first power of the linear dimensions of the evapg. surface, but that when a steady current of air is passed, or is passing, the rate is proportional to the  $3/2$  power of the linear dimension. These results have both been confirmed in practice previously by other workers. A discussion follows of the rate of evapn. from leaves. Evapn. from a single cylindrical stoma is first considered, and it is shown that in many actual cases the total evapn. from a wet leaf would not be as much as that from the combined stomata in the leaf, supposing each stoma to evaporate according to the formula. It follows that evapn. from any stoma must be enormously restricted by the presence of other stomata in its immediate neighborhood.

S. C. LIND.

Two lecture experiments. FR. FICHTER. *Helvetica Chim. Acta* 1, 430-3(1918).—(1) *Avoiding the annoyance due to odor in collecting gases:* The app. was designed for  $\text{H}_2\text{O}$ -sol. gases that are first bubbled through  $\text{H}_2\text{O}$  till air-free and the delivery tube is

then introduced under Hg in the collecting tube. At the top of the collecting tube is sealed a T-tube with a stopcock, the latter between the T and the collecting tube. The stopcock being closed and the tube filled with Hg, one arm of the T-tube is connected to the gas evolution app. (e. g., HCl from NaCl and H<sub>2</sub>SO<sub>4</sub>) and the other arm to a flask of H<sub>2</sub>O. When the gas is being completely absorbed by the H<sub>2</sub>O (i. e., air-free), *slowly* open the stopcock so that the falling Hg column sucks in the gas; when the tube is filled with gas, close the cock and remove the burner. The pressure falls and air enters through the safety tube. (2) *Prepn. of CaC<sub>2</sub> without an electric furnace*: On a compressed layer of CO<sub>2</sub> snow in an Fe dish place powdered Ca (com. Ca coarsely ground in a mortar), mix with loose CO<sub>2</sub> snow, and throw upon the mass some burning metallic Ca (heated in the air). A crackling noise and the emission of sparks accompany the violent reaction, grayish yellow lumps resulting. Place a piece of the product and some H<sub>2</sub>O in a test tube provided with a stopper and delivery tube and ignite the evolved gas, noting the color of the flame which yields soot on cold porcelain. On removing the stopper note the odor of C<sub>2</sub>H<sub>2</sub> and NH<sub>3</sub> (test for latter with moist litmus paper). In order to suppress the formation of nitride, it is advantageous to use a large excess of CO<sub>2</sub> over that required for the equation  $2\text{CO}_2 + 5\text{Ca} = \text{CaC}_2 + 4\text{CaO}$ .

F. W. SMITHER.

Standardization of the Saybolt universal viscosimeter. W. H. HERSCHEL. *Bur. of Standards, Tech. Paper* 112 25 pp. (1918).—The standardization is along the lines of that of the Engler viscometer. The dimensions of four instruments are accurately measured, and appropriate tolerances assigned. The equation which gives the kinematical viscosity, which is the ratio of the abs. viscosity to the density, is  $\mu/\gamma = [k - (mv^2/g)] (\pi g d^4 t) / [128 Q (l + \lambda)]$ , where  $\mu$  is the viscosity in poises,  $\gamma$  the density,  $Q$  the vol. in cc. of the liquid flowing out in  $t$  seconds,  $\lambda$  the Couette correction which is added to the length of the tube to obtain the effective length,  $h$  the average head,  $m$  the coefficient of the kinetic energy correction,  $v$  the mean velocity in cm. per sec.,  $d$  the diameter, and  $l$  the length of the outlet tube. This may be written in the simplified form  $\mu/\gamma = At - B/t$ , where  $A$  and  $B$  are consts., depending on the instrument. By comparison of the times of flow for various liquids in the Saybolt instrument and in a standard Engler instrument the const.  $A$  is detd., and  $B$  is found from  $A$  and the calibration curve with water and alc. solns. By substitution of the dimensions in the complete equation the Couette and kinetic energy corrections are found. The former is 0.54  $d$ , and  $\mu/\gamma = 0.00220t - 1.80/t$ . Ubbelohde's method of obtaining the kinematic viscosity of abnormal instruments from the time of discharge for water is shown to be inaccurate. Conversion tables for Engler, Redwood and Saybolt viscometers are given.

F. C. HOYT.

Constitution of the nucleus and atmosphere of the sun. M. A. VERNONET. *Compt. rend.* 167, 722-5 (1918); cf. *C. A.* 12, 1144.—If the compn. at one point of the sun is known, that at any other may be calcd. by the method given in the previous paper. When the pressure is 1500 atm. the gas attains  $1/3$  of its limiting density, and at the same time the curve of density shows a sharp point of inflection corresponding to the boundary between the nucleus and the atm. In the nucleus the mols. are regarded as diatomic, because of the great pressure, while in the atm. they are monatomic. Assuming a compn. which gives the mean density of 1.41 where the pressure is 1500 atm. a table is given showing the compn. at various depths, for the nucleus and the atm. The marked change in density at the point of inflection makes the atm. analogous to that of the earth. Effects of heating and cooling are briefly discussed. The elements considered are Ta, Ag, Fe, Ca, Na, and H.

F. C. HOYT.

The fourth dimension. J. B. UBINK. *De Nieuwe Gids* 33, 791-802; *Chem. Weekblad* 15, 1269-70 (1918).—It is suggested that the hypothesis of the 4th dimension

may open up fruitful perspectives in the study of stereoisomerism, and of intramol. phenomena in general.

JULIAN F. SMITH.

**Tintometry.** E. SCHELL. *J. Soc. Leather Trades Chem.* 2, 297-9(1918).—In order to match colored cloths with samples, and generally in the use of Lovibond's tintometer, it is necessary that comparisons be made in homogeneous and uniform illumination. This may be attained in a black chamber, illuminated from a source uniformly defined so as to arrive at results which are comparable and independent of the atm. Moore's light, produced by the electric incandescence of  $\text{CO}_2$  in a high and const. vacuum is the light best fitted for this service.

W. B. J.

**The design and test of standards of mass.** U. S. Bur. Standards, *Circular* 3, 8pp.(1918).—This circular treats of the types of weights used as standards of mass and of their design, test, and adjustment. Information is given relating to the manner of using weights, and complete routine for their verification, test and intercomparison is developed. Tables facilitating the comparison of tolerance and precision of corrections, and the computation of corrections, are included.

**Atomic refraction and atomic dispersion of quadrivalent lead deduced from the saturated lead tetraalkyls.** GERHARD GRÜTTNER AND ERICH KRAUSE. *Ann.* 415, 338-62(1918); *J. Chem. Soc.* 114, II, 382-3.—Hitherto, the at. refraction of quadrivalent lead, 17.87 for the red H line ( $n^2$  formula) has been deduced from only 1 compound,  $\text{PbEt}_4$ . Since it is known that the at. refraction of Si, derived from the silanes, varies between 7 and 8, it is desirable that the value for Pb should be recalcd. and for this purpose the numerous Pb tetraalkyls prepd. by G. and K. are well suited, since they are colorless stable liquids. The values of the at. refraction and dispersion of quadrivalent Pb depend on the no. of C atoms in the mol. and increase from  $\text{C}_4$  to about the  $\text{C}_{12}$  compds. The values calcd. from the simple, completely symmetrical Pb tetraalkyls ( $\text{PbR}_4$ ) increase regularly with the mol. wt. G. and K. are decidedly of the opinion that there are no const. values. The at. refraction ( $H_\alpha$  line) increases from 17.07 for the  $\text{C}_4$  compd. to 18.16 for the  $\text{C}_{11}$  compds. and the at. dispersions increase from 1.43 to 1.75 ( $H_\gamma - H_\alpha$ ), and from 0.87 to 1.05 ( $H_\beta - H_\alpha$ ). Certain regularities in the b. p., densities and refractions and dispersions of Pb alkyls and Si alkyls are recorded.

C. J. WEST.

**The ultraviolet spectra of magnesium and selenium.** J. C. McLENNAN AND J. F. T. YOUNG. *Univ. Toronto. Phil. Mag.* 36, 450-61(1918).—Owing to the theoretical interest in the exact values of spectral lines in connection with atomic structure from the standpoint of the quantum theory it has been necessary to make observations far down in the ultraviolet and Schumann regions. The present paper gives the results for Mg and Se. The spectra of Mg for the spark and for the arc both in air and for the arc *in vacuo* have been investigated between  $\lambda = 2000 \text{ \AA. U.}$  and  $\lambda = 2852.22 \text{ \AA. U.}$ , and about 58 new lines have been measured. The line  $\lambda = 2026 \text{ \AA. U.}$  has been

confirmed and support obtained for the existence of the series  $\nu = (1.5S) - (m, p_1)$ . For Se 12 new lines between  $\lambda = 2200$  and  $1850 \text{ \AA}$ . U. have been observed and measured in the spark spectrum, and 5 new lines in the Se arc for the same region. The absorption spectrum of Se metal in the C arc was investigated and a reversal found for  $\lambda = 1960$ , which is the strongest line in both the arc and spark spectra. If the absorption of Se vapor should prove analogous to that of Hg, Zn, and Cd this would indicate that the two series  $\nu = (1.5 S) - (m, p)$  and  $\nu = (1.5 S) - (m, p_1)$  for Se are in the extreme ultraviolet.

S. C. LIND.

**Fundamental frequencies in the spectra of various elements.** J. C. McLENNAN AND H. J. C. IRETON. Univ. Toronto. *Phil. Mag.* 36, 461-72(1918).—With a view to confirming photographically the result of Davis and Goucher (*C. A.* 11, 3173) regarding the potentials at which Hg vapor of low density emits certain radiations, expts. of McL. have been repeated and extended to other vapors. When Zn and Cd vapors are bombarded by electrons of increasing velocity, monochromatic radiation is suddenly emitted when the voltage is that given by the quantum relation for the frequency  $\nu = (1.5 S) - (2, p_1)$ . On further increasing the voltage no additional radiation was observed until that corresponding to  $\nu = (1.5 S) - (2, P)$  was applied. The wave lengths corresponding to both series were then recorded photographically. It was also shown that a Bunsen flame fed with heated vapor of Zn emits a monochromatic radiation  $\lambda = 3075.99 \text{ \AA}$ . U. From the standpoint of electronic vibrations within the atom, it appears that the series  $\nu = (1.5 S) - (m, P)$  is the more fundamental for Hg, Zn, Cd, Mg, Ca, and probably also for Sr and Ba.

#### 4. ELECTROCHEMISTRY.

COLIN G. FINK.

M. O. Leighton. ANON. *Elec. World* 73, 243(1919); illus.—Biographical sketch.  
C. G. F.

**Future of the American electrochemical industry.** S. W. MAHER. *Met. Chem. Eng.* 18, 513-4(1918).—In view of inadequate power for future development of the electrochem. industry, it is doubtful if Niagara Falls will remain the leading electrochem. center of the country. The advantages of the S. W. Appalachian region lying between the Cumberland Mountains on the north and the Blue Ridge System on the south are discussed, and it is pointed out that this territory offers an interesting field for closer investigation, as it has the necessary factors for cheap power, and in addition has raw materials such as salt, lime, coal, bauxite, Fe, Mn, chrome and Ni, as well as assembling and distributing facilities and building materials.

H. JERMAIN CREIGHTON.

**Central stations and the manufacture of electrochemical products.** C. A. WINDER. *Met. Chem. Eng.* 18, 354-6(1918).—W. deals with power consumption in manuf. of numerous electrochem. products, the difficulties encountered due to the relatively high frequency furnished by the central stations and the impracticability of off-peak power. Water power is more economical than steam only when the load factor is 60% or more.

W. H. BOYNTON.

**Some developments in the electrical industry during 1918.** JOHN LISTON. *Gen. Elec. Rev.* 22, 9-47(1919); cf. *C. A.* 12, 2164.—A review.

C. G. F.

**British electric steel furnaces.** F. J. MOFFETT. *Iron Age* 103, 120(1919).—See C. A. 13, 209. W. H. BOYNTON.

**Size vs. recoveries in ferromanganese furnaces.** E. S. BARDWELL. *Chem. Met. Eng.* 19, 749(1918).—B. has examd. a no. of elec. furnaces of the same type working under the same conditions, with transformer capacities between 1500 and 3000 k. v. a. The crucibles consisted of tanks ranging in size from  $7\frac{1}{2} \times 15 \times 4\frac{1}{2}$  ft. deep to  $12 \times 20 \times 9$  ft. deep, with linings of carbon electrode butts. Three-phase, 60-cycle current was used, with 3 electrodes. The voltages varied between 65 in the smaller to 100 v. in the larger furnaces. The charges consisted of Mn ore, coal, Fe turnings, and limestone. In the case of the smaller furnaces, operating at low voltages, the slag loss was low and the volatilization loss almost nil. The larger furnaces operating at higher voltages showed increased loss of Mn in slag and greatly increased volatilization. The effects in the latter case are ascribed to irregular furnace working, excessively high local temperatures, and the formation of carbide and graphite accretions beneath the electrodes. Substituting coke for a part or all of the coal, thereby decreasing the resistance of the charge and making possible a lower operating voltage, is recommended in such cases. A. L. FIELD.

**The aluminium industry in 1918.** ANON. *Metal Ind.* 17, 2(1919). E. H.

**Melting brass in the induction furnace.** G. H. CLAMER. *J. Am. Inst. Metals* 11, 381-95(1917).—C. discusses the general principles of the induction furnace and describes in detail the Ajax-Wyatt type. This furnace employs a closed channel with a pool above and circulation of the liquid metal in the channel. 60/40 brass may be melted without volatilization of Zn in the channels of the secondary circuit so long as the cold metal is being fed into the furnace or the bath has not in entirety reached the volatilization point of Zn. In charging, it is necessary to guard against bridging of the charge. Constant energetic automatic circulation results from the motor effect, pinch effect and Joule effect. The power factors of 30- and 60-kw. furnaces are 85% and 72%, respectively. These furnaces operate on single phase circuit, 220 v., 60-cycle. The furnace as developed is intended only for Cu-Zn alloys containing no more than 3% Pb. W. H. BOYNTON.

**Making electric furnace bottoms.** A. W. LORENZ. *Foundry* 46, 403(1918).—The refractory mixt. used for the bottom should be rammed well in layers an inch thick. FeO should be kept down as this is reduced to Fe by the coke, thus diminishing the strength of the bottom. It is probable that to secure the best results, a basic elec. furnace bottom should contain as little oxidizing material as possible and should be burned-in thoroughly with non-reducing flame. H. JERMAIN CREIGHTON.

**Muscle Shoals nitrate plant.** ANDREW M. FAIRLIE. *Chem. Met. Eng.* 20, 8 (1919).—F. discusses generally the need of nitrates and why a great construction of coke ovens is undesirable. The Haber and arc processes are mentioned and the reason for choosing the cyanamide process is given. The location of the Muscle Shoals plant is described and a tabulation of the important departments given. This plant will require 90,000 kw.; 60,000 v. to be furnished by a steam plant and 30,000 by the Alabama Power Co. Ultimately the hydro-elec. plant will supply the power in addition to the steam plant. Information is given as to the size and kind of boiler room equipment. The elec. current at 12,000 v. will be transmitted to the plant through a special bus tunnel of concrete and brick. A carbide material department pulverizes and dries coal, calcines limestone in rotary kilns 125 ft. in length and of 200 tons' capacity per day, and dries and crushes coke. The carbide furnace dept., with 12 furnaces, will produce 600 tons of  $\text{CaC}_2$  per day, this material then passing to a cooling and crushing dept. containing three  $36'' \times 4''$  Buchanan crushers giving  $1\frac{1}{4}$  inch carbide which

with Hardinge mills and Smidth mills is further pulverized to 200 mesh. A liquid-air plant based on the Claude system will contain 30 N columns. Details of air purification, size of machinery and capacity are given. For cyanamide 1536 ovens are provided. Conversion of cyanamide to  $\text{NH}_3$  takes place in 56 autoclaves, equipped with agitators. Steam and caustic soda free the  $\text{NH}_3$ , which is then catalytically oxidized by platinum gauze to  $\text{NO}$  and  $\text{NO}_2$  and then further oxidized in oxidation towers to  $\text{N}_2\text{O}_4$ . Absorption towers yield the nitric acid. With  $\text{NH}_3$  gas,  $\text{NH}_4\text{NO}_3$  is formed, which is crystallized in proper evaporating pans. The article gives rather full information on the sizes, the construction, the capacities, power used and general operation of each part mentioned above.

EDWIN T. ALLEN.

Construction and operation of an electrolytic copper refinery. J. E. McALLISTER. *Eng. Mining J.* 106, 337-40 (1918).—A detailed description of the probable cost of construction of an elec. refinery to handle 50,000 tons Cu annually. Economic aspects are discussed, the basis of cost estimate is defined, proposed practice outlined, and estimated initial and operating expenses are given. It is assumed that high-tension a. c. can be delivered at low-tension terminals of transformers at the rate of \$15 per h. p. year. The arrangement of the plant is illustrated by a plan. Construction costs amount to \$1,502,800, and operating costs to \$13.112 per T refined Cu, divided as follows: labor \$5.669, material \$1.332, fuel \$1.895, power \$1.301, overhead \$1.378, interest on investment \$1.537.

H. JERMAIN CREIGHTON.

Maintenance of high ampere efficiency in electrolytic copper refining. M. H. MERRISS AND M. A. MOSHER. *Eng. Mining J.* 106, 95-7 (1918).—The importance of freshly cleaned oiled contacts is emphasized and the proper method of hanging the thin cathode starting sheets is described. Anodes and cathodes must be placed equidistant and should be properly centered in the tank. The use of voltmeters to detect short circuits and bad contacts is explained, and the importance of cleanliness discussed. In conclusion a number of pointers are given for the light-copper fixer.

H. JERMAIN CREIGHTON.

Electrolytic silver and gold refining at Perth Amboy, N. J. G. G. GRISWOLD. *Trans. Am. Electrochem. Soc.* 35, 1-7 (1919) preprint.—An illus. description of the refining of Ag and Au bullion by the Moebius process. The vertical type of app. proves the more satisfactory as it insures a greater capacity for a given floor space, smaller tie-up and cheap production of 990 fine or better anodes in connection with a Pb refinery. The tank room contains 24 sections of 6 tanks each, sections in series, and the tanks in multiple. Stoneware tanks supercede the original wooden ones. Ag anodes (2.8 kg.) are cast, weighed, counted, punched and used as required. Cold-rolled Ag sheet 0.8 mm. thick forms the cathodes. Four new anodes in bags and 5 cathodes are suspended in each tank. The neutral nitrate electrolyte contains 15-20 g. Ag, and 30-40 g. Cu per l. A c. d. of 440 amp. per sq. in. is utilized, the current being carried by Cu cables through Hg-filled Cu cups over cold-rolled Cu bus bars. The Au slime after removal of Cu is washed, dried and cast into anodes for refining by the Wohlwill process. This installation has 5 stoneware cells in series with the Ag sections. With the high c. d. required (1650 amp. per sq. in.) osmosis developed in the stoneware causing cracking. Hg cups on the ends of the bus bars allow cut in or out by means of Cu bars. Rolled electrolytic Au cathodes are connected to the contact bars by bending one end around them and clipping fast. The electrolyte contains 30% free HCl, 80-5 g. Au per l. and varying small amounts of Pt and Pd. W. H. BOYNTON.

The electrolytic behavior of manganese in sulfate solutions. G. D. VAN ARSDALE AND C. G. MAIER. *Trans. Am. Electrochem. Soc.* 33, 33-48 (1918).—Exptl. results show that Mn can be deposited at the cathode from neutral sulfate solns. with 80-90%

efficiency at 3 v. or more, but the deposit is powdery, and a concn. of 0.36% free  $\text{H}_2\text{SO}_4$  prevents deposition. It is efficiently deposited as  $\text{MnO}_2$  at the anode from solns. containing 5%  $\text{MnSO}_4$  in the form of a dense, black, lustrous film. Curves show current efficiencies for various c. d.'s and at different temps., and concns. Temp. increase lowers the current efficiency rapidly for cathode deposition, but greatly improves it in the case of deposition as  $\text{MnO}_2$ . Theories for these results are given, and the effect of impurities on the  $\text{MnO}_2$  deposit pointed out.

W. H. BOYNTON.

Electrolytic pickling of steel. C. HERING. *Metal. Chem. Eng.* 18, 282(1918).—Polemical (cf. C. A. 12, 790-1). In the removal of scale by the electrolytic process there is much less attendant loss of metallic iron and of  $\text{H}_2\text{SO}_4$  than by the chem. process.

W. H. BOYNTON.

Review of the plating industry for 1918. CHARLES H. PROCTOR. *Metal Ind.* 17, 15-7(1919).

E. H.

Nickel solutions. E. P. LATER. *Foundry* 46, 213-5(1918).—Troubles with the plates are considered and some remedies discussed. It is pointed out that if the bath is too acid or the metal content too low, the Ni deposit will peel. A deposit with a yellowish tinge is due to an alk. condition of the bath, which may be corrected by the addition of  $\text{H}_2\text{SO}_4$ . In conclusion a number of suggestions for cleaning are given.

H. JERMAIN CREIGHTON.

Nickel plating cast or sheet aluminium. C. H. P. *Metal Ind.* 17, 25(1919).—After cleaning, polishing, etc., the Al is plated at 3-3½ v. in a soln. containing: Water 3.791,  $\text{NiSO}_4 \cdot 7\text{H}_2\text{O}$  284 g.,  $\text{NiSO}_4(\text{NH}_4)_2\text{SO}_4 \cdot 6\text{H}_2\text{O}$  56.7 g.,  $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$  56.7 g., and  $\text{H}_3\text{BO}_3$  56.7 g. A double-throw switch is used, whereby the Al articles are momentarily made the anode, and the oxide film is dissolved. Then, reversing the switch, the articles become cathode and Ni is deposited. Contamination of the acid dip or deoxidizing soln with Cu is prevented by the use of soft iron for stringing purposes. This also maintains the Fe necessary in the dip. After Ni plating, Al articles may be plated in any cyanide bath for brass, Cu, Ag or Au.

W. H. BOYNTON.

Preparation and use of rapid nickel baths. E. P. LATER. *Foundry* 46, 23-5(1918).—Good deposits have been obtained from a bath containing 32 oz.  $\text{NiSO}_4$ , 3 oz.  $\text{NiCl}_2$  and 3 oz. boric acid per gal. when working under the following conditions: 49 amp./sq. ft. at 25°, 130 amp./sq. ft. at 25°, 295 amp./sq. ft. at 67°, 422 amp./sq. ft. at 71° and 890 amp./sq. ft. at 92°. In the operation of hot baths the regulation of the acidity is of importance, as hot baths quickly become alk., with the resultant production of dull deposits. Furthermore, the conductors must be able to handle the current without heating.

H. JERMAIN CREIGHTON.

Zinc cyanide plating solutions. F. J. LISCOMB. *Metal Ind.* 16, 552-3(1918).—The desired concns. of  $\text{Zn}(\text{CN})_2$ , NaCN and NaOH may be economically obtained by use of  $\text{ZnO}$ , NaCN and NaOH. Equations and examples are given. The economy is dependent upon market prices of the reagents, but results are equal to those obtained by the use of  $\text{Zn}(\text{CN})_2$ .

W. H. BOYNTON

Electro-galvanizing booster cases, adapters, and detonator fuse components for the United States Government. T. C. EICHSTAEDT. *Metal Ind.* 17, 22-4(1919).—A detailed description of the processes and equipment used. Steel racks hold 12 booster cases and have 10 small Zn anodes, each of which has a cotton stocking to prevent particles of Zn from falling into the cases. Thirteen anodes run crosswise of the tank and a cathode rod runs lengthwise along the side of the tank. The tank is fitted along the top on each side with Cu buss bars upon which anode rods are placed and make a contact. On the anode rods are suspended 5 elliptical Zn anodes 6 in. (15.2 cm.) long. The inside anode holders are drilled on each end to fit on pins in the

buss bars. Plating required 20 min. at 2 v. and 275-300 amp. Adapters are handled on steel wire trees with brass hooks to fit the conveyor plating tank. After cleaning, pickling and rinsing, the adapters are dipped into a soln. containing 15 g. NaCN per 3.79 l., then into a Zn strike soln. and thence to the plating tank. The plating soln. contains: Water 3.79 l.,  $\text{Zn}(\text{CN})_2$  170 g., NaCN 170 g., NaOH 57 g.,  $\text{SnCl}_2$  28 g., soda ash 57 g., and is used at 43-9°. Detonator fuses have 4 parts to galvanize: cap, washer, safety pin, and firing pin. The standard electro-galvanizing soln. consists of a strike and a finishing soln.— $1\frac{1}{2}$  hr. in each soln. The plating is made automatic as nearly as possible by use of rotary cleaning app., self-emptying bbls. with self-emptying rinsing and drying app.

W. H. BOYNTON.

**A new lead plating solution.** J. HAAS, JR. *Metal Ind.* 17, 12(1919).— $\text{Pb}(\text{CN})_2$  is prepd. by dissolving Pb in  $\text{HNO}_3$ , eliminating excess of the latter, and adding enough NaCN just to ppt. the  $\text{Pb}(\text{CN})_2$ . The ppt. is allowed to settle the soln. syphoned off, water added, the mixt. boiled, the undissolved  $\text{Pb}(\text{CN})_2$  allowed to settle and the soln. electrolyzed. The voltage is maintained at 1.75 v. with a max. c. d. of 4 amp. per sq. ft. (928.6 sq. cm.) and the temp. at 70°. The anodes are coated heavily white. By addition of 170 g.  $\text{KNaC}_4\text{H}_4\text{O}_6$  per 3.79 l., a const. current strength is maintained, anodes are kept clean, and the same deposit is obtained.  $\text{Pb}(\text{CN})_2$  is suspended from the sides in bags. By boiling the soln. toward evening it will remain warm enough to prevent settling out of  $\text{Pb}(\text{CN})_2$  during the night. W. H. BOYNTON.

**Planning a metal finishing department.** ANON. *Metal Ind.* 17, 5-6(1919).—An itemized estimate for complete equipment of a plating room, already partially outfitted. The arrangement is illustrated.

W. H. BOYNTON.

The Cottrell processes in the sulfuric acid industry (HEIMROD, EGBERT) 18. Design of transmission line porcelain insulators (GILCHRIST, KLINEFELTER) 19. Annual review on the various metals, metal products, ores, etc., for 1918 9. Unique features of an Illinois foundry (LUNDBERG) 9. Perkin medal award to Dr. Cottrell 18.

**Dry cell electric battery.** N. K. CHANEY. U. S. 1,287,634, Dec. 17. C is prepd. for use in the mixt. of a dry cell battery (after mixing with  $\text{MnO}_2$ ) by wetting it with an acid, e. g., HCl,  $\text{HNO}_3$  or  $\text{H}_2\text{SO}_4$ , adding an oxidizing agent such as  $\text{Ca}(\text{OCl})_2$  or  $\text{H}_2\text{O}_2$  to oxidize the FeS present and then adding sufficient ZnO to neutralize any excess acid. This treatment increases the voltage and "shelf life" of dry cells.

**Electrolytic iron.** A. T. C. ESTELLE. Can. 188,462, Jan. 28, 1919. Fe compds. are treated with caustic alkali at high temp. and the slime produced is subjected to electrolysis.

**Electric furnace.** W. K. BOOTH. U. S. 1,287,849, Dec. 17. A monolithic mass of  $\text{CaC}_2$  is used for the wall-contact of the furnace.

**Electric furnace suitable for iron or steel making and for reducing ores.** L. L. SIMPSON. U. S. 1,288,240, Dec. 17. The pat. relates especially to water-jacket construction.

**Three-phase electric furnace.** F. T. SNYDER. Can. 188,104, Jan. 7, 1919. The furnace has two upper electrodes and a bottom control and reactance is provided in the path of lowest resistance of such unit as automatically to equalize the currents flowing in the different phases of the polyphase system.

**Electric induction furnaces.** O. C. BOCKMAN. Can. 188,205, Jan. 14, 1919. In each phase of the furnace is arranged a regulable path for the magnetic flux in parallel with the ordinary flux path in order to regulate each sep. phase of the furnace independently of the other phases and of the current on magnetic coils.

**Treating gases in the electric arc.** F. H. A. WIELGOLASKI. U. S. 1,287,807, Dec. 17. The pat. relates to an app. and method of use for treating gases, such as air for fixing N, in such a manner as to prevent, so far as possible, decompn. of the product. Gases to be treated are introduced into the arc chamber along substantially its entire length, conducted toward the arc so as to effect a relatively prolonged contact of the gases with the arc and are then withdrawn through a restricted outlet through a hollow electrode into a cooled chamber in which a materially lower pressure is maintained than in the arc chamber. U. S. 1,287,808 relates to a method of arc-treatment of gases with elongated bent arcs, in which insulating walls of transversely moving cold gases are maintained between the bends of the arcs to prevent short-circuiting of the arc upon itself.

**Ammonia from the elements.** A. CLASSEN. Norw. 28,990, Aug. 5, 1918. N and H are subjected, in the presence of contact substances, to the action of elec. discharges. Cf. C. A. 12, 884.

**Metallic cerium.** A. and M. HIRSCH. Can. 188,090, Dec. 31, 1918. A cerium salt is prepd. and electrolyzed at a bath temp. of about  $850^{\circ}$ , terminal voltage 12 and amperage over 200. The temp. of the bath is finally raised to promote the agglomeration of the deposited metal. Cf. C. A. 12, 1860.

## 7. ANALYTICAL CHEMISTRY.

E. G. R. ARDAGH.

**Elimination of the volume of a precipitate.** H. D. STEENBERGEN. *Tilburg. Chem. Weekblad* 15, 1268-9(1918).—In analyses in which the soln. is filled up to a known vol., the method of double diln. can be used for accurate correction of the error due to the vol. of the ppt. It is shown mathematically when the sample is dild. to 100 and to 200 cc., the correction to be applied is  $Cv^2/(200-v)(100-v)$ , where  $v$  is the vol. of the ppt. and  $100C$  is the total quantity of the substance under analysis present in the sample.

JULIAN F. SMITH.

**Calculation of the error in a volumetric analysis.** V. ZOTIER. *Bull. sci. pharmacol.* 25, pt. 2, 274-82(1918); cf. *Bull. sci. pharmacol.* 24, 298(1917).—A discussion, replete with mathematical formulas and examples, taking into consideration the errors due to app., indicators, and the solns. themselves.

M. HEIDELBERGER.

**Improved method of sulfur analysis.** F. G. HAWLEY. *Eng. Mining J.* 105, 385-6(1918).—H. recommends the following method for detg. S (except that present as  $\text{BaSO}_4$ ) in ores and furnace products: Weigh 0.5 to 1 g. of the sample into a 400-cc. Griffin beaker, cover with a watch glass, add 10 cc. of a 20% aq. soln. of  $\text{NaClO}_3$ , and 7 to 15 drops of a mixt. of equal parts of Br and glacial AcOH. Add 10 cc. of  $\text{HNO}_3$  nearly satd. with  $\text{KClO}_3$  and shake until sample and soln. are mixed. If the S content is high it may be advisable to place the beaker in a cooling bath or trough for a few min. In 2 or 3 min., or as soon as no unoxidized S can be seen, place the beaker on the hot plate and evap. carefully to dryness. Cool, add 5 cc. of  $\text{HCl}$  (3:2) and again evap. to dryness; take up with 10 cc. of  $\text{HCl}$  (3:2), heat until all sol. matter is dissolved, dil. to 150 cc., neutralize with  $\text{NH}_4\text{OH}$ , and add 10 cc. in excess. If Pb is present, add about 1 g. of  $(\text{NH}_4)_2\text{CO}_3$ . Heat to boiling and boil 1 min.; filter through a 15-cm. paper and wash 6 or 7 times, boil the filtrate to expel most of the  $\text{NH}_3$ , neutralize with  $\text{HCl}$ , and add 2 to 3 cc. in excess. Add dropwise 3 to 5 cc. of 10%  $\text{BaCl}_2$  soln. and then run in at once about 10 cc. more; boil 10 min., let settle, filter, wash, ignite, and weigh as  $\text{BaSO}_4$ . If the sample contains less than 1% of S, it is better to evap. to a vol. of 100 cc. or less, to use a smaller excess of  $\text{HCl}$ , to boil longer, and to let

stand overnight. H. reports results on a mat (25.6% S), showing excellent agreement of the method with the Allen and Bishop and other procedures; the aqua regia method indicated less than 20% of S. F. W. SMITH.

**Determination of molybdenum in ores.** W. J. CROOK AND M. L'A. CROOK. *Mining Sci. Press* 117, 313-4(1918).—The authors recommend the following: *Volumetric methods:* (1) For ores or Fe-Mo. Fuse in a Ni crucible 0.5 to 1 g. of the sample with 4 g.  $\text{Na}_2\text{O}_2$  till liquid; continue heating for 5 min. more and run the fusion up on the sides of the crucible (the temp. should not exceed a dull red heat). Cool, ext. with  $\text{H}_2\text{O}$  in a beaker and rinse the crucible; boil down to about 150 cc., filter, wash with hot  $\text{H}_2\text{O}$  and acidify the filtrate with  $\text{AcOH}$ . Heat to boiling and titrate the colorless soln. with  $(\text{AcO})_2\text{Pb}$  soln. (25 g. + a little  $\text{AcOH}$ , dild. to 1 l.), using tannic acid (0.1 g. in 30 cc.  $\text{H}_2\text{O}$ ) as an outside indicator. When much Fe is present in the sample, fuse 10 g.  $\text{NaOH}$  in a Ni crucible till a pasty mass is formed; mix the sample with 3 g.  $\text{Na}_2\text{O}_2$  and carefully add the mixt. portionwise. When the fusion is complete, add 3 g. more of  $\text{Na}_2\text{O}_2$  and conduct the fusion as before. The authors describe in detail the prepn. of  $\text{PbSO}_4$ , its use in standardizing a standard  $(\text{NH}_4)_2\text{MoO}_4$  soln., and the use of the latter to det. the titer of the  $(\text{AcO})_2\text{Pb}$  soln. (2) Dissolve 2 g. of the sample in 20 cc.  $\text{HNO}_3$ , 20 cc.  $\text{HCl}$ , and 20 cc.  $\text{H}_2\text{O}$ . After 10 or 15 min. add 20 cc. of 60%  $\text{H}_2\text{SO}_4$  and evap. until copious fumes are evolved. Cool, dil., filter off  $\text{PbSO}_4$  and siliceous matter, heat the filtrate to boiling and add a few crystals of  $(\text{NH}_4)_2\text{S}_2\text{O}_8$ ; boil a few min. to destroy the persulfate, cool, and ppt. with  $\text{H}_2\text{S}$  for 1 hr. Boil for a few min. and filter; wash with  $\text{H}_2\text{S}$  water. Transfer as much of the ppt. as possible back to the beaker with  $\text{H}_2\text{O}$ ; dissolve that remaining on the paper with boiling dil. aqua regia (1 part  $\text{HNO}_3$ , 1 part  $\text{HCl}$ , and 3 parts  $\text{H}_2\text{O}$ ), receiving the soln. in the beaker containing the ppt., and boil until all is dissolved. Filter off any S, add 5 cc. of 60%  $\text{H}_2\text{SO}_4$  and evap. till white fumes are evolved; cool, dil. to about 60 cc., and neutralize with  $\text{NH}_4\text{OH}$  (1:1) till there is a distinct odor of  $\text{NH}_3$ . If a white or yellowish ppt. of Bi forms, filter. Neutralize the soln. with  $\text{AcOH}$ , add 5 g.  $\text{AcONa}$  and titrate with  $(\text{AcO})_2\text{Pb}$  as above. (3) Useful when Mo and W are present in the same sample. Weigh out the sample and fuse as in (4). Dissolve the melt in hot  $\text{H}_2\text{O}$ , and filter; boil the filtrate and add 20 cc. of Mdivani's reagent (50 g.  $\text{SnCl}_2 \cdot 2\text{H}_2\text{O}$  in 200 cc. concd.  $\text{HCl}$ ) for each 0.15 g. of  $\text{WO}_3$  present. The vol. of the soln. should be kept between 60 cc. and 300 cc. according to the amt. of W present. Boil for 3 min., filter, and wash the blue ppt. with hot 5%  $\text{HCl}$  till the filtrate gives no test for Mo when tested as follows: If a drop of a satd.  $\text{HgNO}_3$  soln., followed by from 1 to 1.5 cc. concd.  $\text{HCl}$  and an excess of  $\text{KI}$  is added to the soln. to be tested, and the mixt. shaken until the  $\text{HgI}$  is completely dissolved, the presence of Mo or W is indicated by a blue color, developed either at once or after a short time. Test for Mo by adding  $\text{KCNS}$  and extg. with ether (blood-red to orange color). If the estn. of W is required, ignite the blue ppt. in a porcelain crucible, and weigh as  $\text{WO}_3$ . Evap. the filtrate to a small vol., cool, transfer to a 250-cc. volumetric flask and dil. to mark; mix and transfer 50 cc. to a beaker, add 5 to 10 g. of sheet Zn to ppt. the Sn, let stand 10 min., filter, and wash the residue with hot  $\text{H}_2\text{O}$ . Heat the filtrate to  $60^\circ$ , and pass through a Jones reductor (50 cc. 2.5%  $\text{HCl}$ , then the Mo soln., then 150 cc. of 2.5%  $\text{HCl}$ , and finally 150 cc. hot  $\text{H}_2\text{O}$ ) into 20 cc. of 10%  $\text{Fe}^{+++}$  alum soln. + 20 cc. of "titrating soln." (90 g.  $\text{MnSO}_4$ , 650 cc.  $\text{H}_2\text{O}$ , 175 cc.  $\text{H}_3\text{PO}_4$ , and 175 cc.  $\text{H}_2\text{SO}_4$ ). Titrate with 0.1 N  $\text{KMnO}_4$ , correcting for a blank ( $\text{Fe} \times 0.605 = \text{Mo}$ ). *Gravimetric methods:* (4) Mix 0.3 g. of the sample with equal parts of  $\text{Na}_2\text{CO}_3$  and  $\text{Na}_2\text{O}_2$ , and fuse in a Ni crucible, finishing at a bright red heat. Cool, dissolve the melt in hot  $\text{H}_2\text{O}$  and filter; treat the filtrate with an excess of yellow  $(\text{NH}_4)_2\text{S}_x$  and warm on the  $\text{H}_2\text{O}$ -bath. Add portionwise a slight excess of dil.  $\text{H}_2\text{SO}_4$ , blow a current of air through the soln. to remove

the excess of  $\text{H}_2\text{S}$ , filter, wash, and dry the ppt. Remove as much as possible of the ppt. from the paper to a porcelain crucible; burn the filter separately, and add the ash. Convert the  $\text{MoS}_3$  to  $\text{MoO}_3$  by heating over a small flame, cool, and weigh. (5) Digest 0.3 g. of the sample with 25 cc. of fuming  $\text{HNO}_3$  for several hrs., and evap. to dryness. Treat the residue with 2 or 3 cc.  $\text{H}_2\text{SO}_4$  and take up with 50 cc.  $\text{H}_2\text{O}$ ; filter while warm, wash with  $\text{H}_2\text{O}$ , with dil.  $\text{NH}_4\text{OH}$ , and again with  $\text{H}_2\text{O}$ ; ppt. the Al and Fe in the filtrate with  $\text{NH}_4\text{OH}$ , filter, evap. the filtrate to 150–200 cc., and add an excess of yellow  $(\text{NH}_4)_2\text{S}_x$ . If present, filter off CuS, add HCl, and warm the soln. Filter off the  $\text{MoS}_3$ , evap. the filtrate to dryness, and expel most of the  $\text{NH}_4$  salts; cool, dissolve the residue in  $\text{NH}_4\text{OH}$ , and add  $(\text{NH}_4)_2\text{S}$ . Filter, add the ppt. of  $\text{MoS}_3$  to that previously obtained; ignite the ppts. with S in a current of H, cool and weigh as  $\text{MoS}_3$  (or ignite to  $\text{MoO}_3$ ). (6) U. S. Bureau of Mines' method for ores containing only traces of As or Sb. Digest 0.2 to 0.5 g. of sample with 25 to 35 cc. of fuming  $\text{HNO}_3$  for 3 hrs., and finally evap. to dryness. Add 3 cc. concd.  $\text{H}_2\text{SO}_4$  and evap. until copious fumes are evolved. Cool, dil. to 100 cc., filter, and wash with  $\text{H}_2\text{O}$ . Then wash the residue well with  $\text{NH}_4\text{OH}$  (1:3), and finally with  $\text{H}_2\text{O}$ ; render the filtrate ammoniacal, heat, filter, and wash well with hot  $\text{H}_2\text{O}$ . Sat. the alk. filtrate with  $\text{H}_2\text{S}$  to a bright cherry-red color, filter, and wash with hot  $\text{H}_2\text{O}$ ; render the filtrate slightly acid with HCl and digest until the ppt. and the S are coagulated and the excess  $\text{H}_2\text{S}$  is expelled. Filter through a weighed gooch; evap. the filtrate to dryness and drive off the  $\text{NH}_4$  salts at a low temp., being careful not to heat the dish to redness. Cool, take up the residue with 100 cc.  $\text{H}_2\text{O}$  and 5 cc.  $\text{NH}_4\text{OH}$ , add 10 cc.  $(\text{NH}_4)_2\text{S}$ , make faintly acid with HCl, and digest till the sulfide has coagulated. Filter through the gooch previously used, add an amt. of S to the combined sulfides equiv. to about  $\frac{1}{2}$  their wt., and ignite over a Bunsen burner at a dull red heat in a current of As-free H; cool, and weigh as  $\text{MoS}_3$ . A bibliography is appended.

F. W. SMITHER.

A method for the separation and determination of barium associated with strontium. F. A. GOOCH AND M. A. SODERMAN. *Am. J. Sci.* 46, 538–40 (1918).—A modification of the Mar procedure for sepg. Ba from Ca and Mg (cf. *Am. J. Sci.* [3] 43, 521 (1892)). Dissolve the dry mixed chlorides, contained in a beaker, in the least possible amt. of  $\text{H}_2\text{O}$  (beginning with about 0.2 cc. and, if necessary, adding more later), warming gently, with agitation, and then cooling. If crystals sep. on cooling, cautiously repeat the operation until a cold satd. soln. is obtained. Then add a 4:1 mixt. of 33% HCl and ether, dropwise and with const. agitation during the addition of the first 2 or 3 cc. of the precipitant. Then add the mixt. in amts. necessary to complete the pptn. of  $\text{BaCl}_2$  and dissolve the  $\text{SrCl}_2$  (50 to 75 cc. for amts. not exceeding 0.5 g. of the mixed salts nor 0.3 g. of anhydrous  $\text{SrCl}_2$ ). Decant the liquid upon asbestos in a gooch, and wash and transfer the residue to the filter with a 4:1 mixt. of concd. HCl (38%) and ether (applied in a fine jet from a small wash bottle); dry at  $150^\circ$  and weigh as anhydrous  $\text{BaCl}_2$ . The results reported of expts. made with weighed amts. of  $\text{BaCl}_2 \cdot 2\text{H}_2\text{O}$  and anhydrous  $\text{SrCl}_2$  show excellent agreement with theory.

F. W. SMITHER.

Influence of iron and organic matter on the iodometric estimation of chromium. R. LAUFFMANN. *Collegium* 1918, 223–8; *J. Soc. Leather Trades Chem.* 2, 308.—Cr was estd. iodometrically in a soln. of  $\text{Cr}_2(\text{SO}_4)_3$  (a) without and (b) with  $\text{FeCl}_3$ , and (c) with cane sugar, glucose, starch and sol. protein oxidized by  $\text{Na}_2\text{O}_2$  and by fusion mixt. When  $\text{FeCl}_3$  was used, the  $\text{Fe}(\text{OH})_3$  resulting from the  $\text{Na}_2\text{O}_2$  treatment was either (d) dissolved by excess HCl or (e) filtered off. In the soln. treated with  $\text{Na}_2\text{O}_2$  results were too high in (d) owing to the sepn. of I and too low in (e) from the adsorption of Cr soln. by the  $\text{Fe}(\text{OH})_3$ . Large amts. of organic matter in (c) caused inaccuracy by retarding I sepn. and the consequently indistinct end-point. If hydroxides of bases which do not sep. I and which are sol. in acid, result from the  $\text{Na}_2\text{O}_2$  treatment

they should be filtered off, dissolved in acid, and the Cr therein detd. iodometrically.

W. B. J.

Determination of small quantities of arsenic. O. BILLETER. *Helvetica Chim. Acta* 1, 475-98(1918).—The sulfuric acid soln. resulting from the Johnson-Chittenden method employed on org. matter, is distd. with NaCl. The HCl in the distillate is destroyed with HClO, Cl being evolved. The resulting liquid which now contains As<sup>3</sup>, is taken up with H<sub>2</sub>SO<sub>4</sub>, and transferred to the Marsh app. L. J. ROGERS.

Note on the gasometric determination of nitrates. C. A. HILL. *Analyst* 43, 215-6(1918).—An external reaction bottle is used in connection with the usual Hg-charged nitrometer. It is previously filled with a gas (CO) inert towards nitric oxide. ERLE M. BILLINGS.

The ignition of boric acid. C. R. BAGSHAW. *Analyst* 43, 138-9(1918).—Expts. are cited to prove that the detn. of boric acid in powder or ointment by ignition tends towards low results. ERLE M. BILLINGS.

Sulfide precipitation of group 2 (a) metals. JOSEPH SHIBKO. *Chem. News* 117, 253-4(1918).—For pptg. metals of this group (Cu, Cd, Pb, Hg, Sn) (NH<sub>4</sub>)<sub>2</sub>S is not recommended when Zn is present. The sulfides are slightly sol. in acid solns. and any excess of (NH<sub>4</sub>)<sub>2</sub>S would cause NH<sub>3</sub> to be liberated, thus pptg. some Zn. The use of H<sub>2</sub>S is preferred. ERLE M. BILLINGS.

Microchemical analysis and the detection of counterfeit coinage. F. WEEHUIZEN. *Geneesk. Tijdschr. voor Ned. Indië* 58, 198-200; *Chem. Weekblad* 15, 1521(1918).—A description of the microchem. detection of various metals, in connection with legal practice. JULIAN F. SMITH.

Comments on the analysis of anti-friction metals. R. NAMIAS. *Ind. chim. min. met.* 5, 130(1918).—In reply to the criticisms of Ferreri and Cavalli (*C. A.* 12, 2295) on his method of analysis (*C. A.* 12, 2294) N. states that he has not been able to verify the error due to lead which they report, but that after treatment with HNO<sub>3</sub> the residue is free from lead. There is no loss of Sb<sub>2</sub>O<sub>3</sub> by volatilization from the mixt. of oxides when, as in this case, there is much Sn and little Sb. Considerable Cu remains with the Sn, but can be removed and detd. accurately by fusion of the oxides with caustic and repeated treatment with HCl. The pptn. of Sb by means of Sn is much less troublesome than the authors state, and has the advantage of giving a delicate visible control. When there still remains a little Sb in the soln. after treatment with Sn and filtration, on adding a fresh piece of Sn and boiling a crit. concn. of acid is reached when the remaining traces are deposited as a black ppt. J. S. LAIRD.

A study of the test for tartrates depending upon the formation of the copper-tartrate complex. L. J. CURTMAN AND B. R. HARRIS. *J. Am. Chem. Soc.* 41, 207 (1919).—A correction. Phosphates and borates, even in amts. as high as 500 mg., do not respond in the same way as tartrates when treated by Böttger's procedure as previously stated (cf. *C. A.* 12, 31). E. J. C.

Determination of dextrose with hypoiodite. RICHARD WILLSTÄTTER AND GUSTAV SCHUDERL. *Akad. Wiss. München. Ber.* 51, 780-1(1918).—The method has the advantages of being rapid, accurate with small amts. and applicable even in the presence of ketoses. The course of the reaction depends only on suitable concns. and amts. of alkali. The hypoiodite soln. must not be too strongly alk., as it then reacts too slowly, while the hexose in the alk. medium undergoes the well known changes and, moreover, the gluconic acid formed is further oxidized during the reaction. The amt. of alkali must not be too small, however; it should at least be sufficient to neutralize the gluconic acid formed. The reaction proceeds very rapidly and smoothly with 0.1 N solns. of I and NaOH in the proportions corresponding to the equation HOCH<sub>2</sub>[CH-

$(\text{OH})_6\text{CHO} + \text{I}_2 + 3\text{NaOH} = \text{HOCH}_2[\text{CH}(\text{OH})_6]\text{CO}_2\text{Na} + 2\text{NaI} + 2\text{H}_2\text{O}$ . The glucose soln. is treated with about 2 times (1.5–4 times) the necessary amt. of  $N$   $\text{I}_2$ , then drop by drop at room temp. with shaking with 1.5 vols. of 0.1  $N$   $\text{NaOH}$ , allowed to stand 1.2–5 min. (with very small amts. of sugar, better 20 min.), then made faintly acid with dil.  $\text{H}_2\text{SO}_4$  and titrated with  $\text{Na}_2\text{S}_2\text{O}_3$ . In concns. of 1% glucose (e. g., 100 mg.) the greatest error is 0.1 mg.; the average error was a few hundredths of 1%; and in concns. of 0.1% (10 mg.), the error of individual detns. was less than 1.5%. Under the above conditions cane sugar and fructose use up no  $\text{I}_2$ . C. A. ROULLER.

**An iodine-tannin reagent.** I. D. E. TSAKALOTOS AND D. DALMAS. *Bull. soc. chim.* 23, 391–400 (1918).—This reagent consists of a mixt. of 1 cc. of 0.1  $N$  iodine and 1 cc. of 1% tannin soln., freshly prepared before each detn. It is used for *estg. the degree of alkalinity of solns.* particularly when very dil., giving good results with alk. solns. 0.000025  $N$ . A constant of 245 is used, as it is with this number that the calcd. iodotannic values approach nearest the degrees of alkalinity of the solns. in terms of  $\text{CaO}$ . The method consists in adding the liquid to be titrated from a buret in small portions to the reagent until an intense red color persists, then making very small additions of the liquid and also 5 cc. of starch soln. after each addition from the buret. When the starch soln. added ceases to give any blue color, the end-point has been reached and the iodotannic value, ( $A$ ), is obtained by dividing the number of cc. of soln. used for titration into the constant 245, and the result, with necessary corrections from tables, compares very closely with the degree of alkalinity found by acidimetric titration with indicators. Tests were run on different solns. of  $\text{KOH}$ ,  $\text{K}_2\text{CO}_3$ ,  $\text{Na}_2\text{CO}_3$ ,  $\text{NH}_4\text{OH}$ ,  $\text{Ca}(\text{OH})_2$ , of from 0.01  $N$  to 0.0001  $N$ , and the results obtained were very close to those found by other methods. Conc'd. alk. solns. can be directly titrated, but the most satisfactory way is to dil. with a known vol. of water and make a correction for the iodotannic value of the water added. The method was found adaptable to the estn. of the alkalinity of drinking waters, etc., and for detg. the alkalinity of org. liquids, such as blood, saliva, etc. J. E. CLARK.

Method for the preparation of soluble starch (SMALL) 28.

## 8. MINERALOGICAL AND GEOLOGICAL CHEMISTRY.

EDGAR T. WHERRY AND J. H. BOWER.

**New mineral names.** W. E. FORD. Yale Univ. *Am. J. Sci.* 45, 477–8 (1918).—Continuing the series (cf. C. A. 12, 344), F. lists 5 additional minerals described during the latter part of 1917 and the early part of 1918. E. T. W.

**Chubutite and the significance of its halogen content.** E. RIMANN. *Anales. soc. quim. Argentina* 6, 323–8 (1918).—In a communication read before the Chem. Soc. of Argentina (C. A. 13, 298) H. Corti described "chubutite," a  $\text{Pb}$  mineral from Chubut, Argentina, which had been studied by R. Beder and F. Pastore and shown to have the formula  $7\text{PbO} \cdot \text{PbCl}_2$ . R. compares this mineral with other oxychlorides of  $\text{Pb}$ , especially loretoite, which was given the formula  $6\text{PbO} \cdot \text{PbCl}_2$  (Wells and Larsen, C. A. 11, 131). Chubutite has  $d. = 7.95$ , loretoite has  $d. = 7.39$ ; unfortunately the  $\eta$ s. of chubutite were not detd. It is possible that chubutite and loretoite are the same mineral. R. C. WELLS.

**Lattice-like inclusions in calcite from North Burgess, Ontario.** R. P. D. GRAHAM. *Mineral. Mag.* 18, 252–8 (1918).—The pale blue calcite from North Burgess township, Lanark Co., contains lattice-like inclusions of a hydrous  $\text{Mg}$  silicate. The white needles are arranged in three directions corresponding to the edges of the rhombohedron

(01 $\bar{1}2$ ), and may be sepd. from the enclosing  $\text{CaCO}_3$  by treatment with cold dil. acid. Apparently the needles were deposited along capillary channels developed by secondary twinning and are considered pseudomorphous in character. When examd. under the microscope they transmit very little light, have straight extinction, weak or medium birefringence and a sp. gr. about 2.50. The av. of 2 analyses gave:  $\text{SiO}_2$  56.80,  $\text{MgO}$  30.39,  $\text{FeO}$  2.06,  $\text{CaO}$  0.37,  $\text{H}_2\text{O}$  10.87%, which corresponds closely with the formula  $5\text{MgO} \cdot 6\text{SiO}_2 \cdot 4\text{H}_2\text{O}$ , which is that usually assigned to spadaite. Two possible sources are suggested for the Mg solns., either the original limestone contained some Mg which was set free and rendered available in the form of a soln. of Mg silicate during the metamorphism of the limestone; or alteration of Mg silicates contained in the cryst. limestone may have provided the necessary solns. W. F. HUNT.

The datolite locality near Westfield, Mass. EARL V. SHANNON. *Am. Mineral.* 4, 5-6(1919).—The occurrence of datolite in the diabase is described in detail. This mineral crystd., together with calcite and small amts. of other minerals, from mineralizing solns. which spread outward from fissures and entered open spaces between blocks of trap displaced by shearing and faulting. E. T. W.

Racewinite: a peculiar mineral from ore deposits in Utah. A. N. WINCHELL. *Econ. Geol.* 13, 611-5(1918).—This mineral comes from the Highland Boy mine, Bingham; in the mine it resembles chlorite. The color is bluish green on fresh fracture, changing slowly to black in air or water. It changes to yellow-brown in  $\text{HNO}_3$ , but remains insol.; partly sol. in  $\text{HCl}$  and changes color, as with  $\text{HNO}_3$ . Other properties are: fragile;  $H. = 2.5$ ; sp. gr. = 1.94-1.98, mean  $\bar{x} = 1.51$ ;  $\gamma - \alpha$  about the same as quartz; biaxial and negative, with large axial angle; no visible cleavage. Two analyses agree closely, one giving:  $\text{SiO}_2$  43.92,  $\text{Al}_2\text{O}_3$  23.68,  $\text{Fe}_2\text{O}_3$  7.37,  $\text{MgO}$  0.50,  $\text{CaO}$  2.52,  $\text{H}_2\text{O}$  22.04%. Also  $\text{FeO} = 0.60$  in a fresh sample. It loses part of its water on exposure to dry air, and regains it in moist air. A. B. PECK.

The color change in vivianite and its effect on the optical properties. THOMAS L. WARSON. Univ. Va. *Am. Mineral.* 3, 159-61(1918).—When colorless vivianite is ground it rapidly becomes blue, and chem. study has been undertaken to det. the cause of this change. The increase in depth of color, and the corresponding change in optical properties, were found to be correlated with the oxidation of  $\text{Fe}^{+2}$  to  $\text{Fe}^{+3}$ . E. T. W.

Iron as a cause of blue colors in minerals. EDGAR T. WHERRY. *Am. Mineral.* 3, 161(1918).—It is pointed out that several minerals besides vivianite (preceding abstr.) show blue colors due to the presence of both  $\text{Fe}^{+2}$  and  $\text{Fe}^{+3}$ , notably, crocidolite, iolite, and blue tourmaline or indicolite. E. T. W.

Glauberite crystal cavities in the Triassic rocks in the vicinity of Gettysburg, Pa. GEORGE W. STOSE. U. S. Geol. Survey. *Am. Mineral.* 4, 1-4(1919).—The discovery of cavities from which glauberite had dissolved out in more or less altered Triassic sedimentary rocks is described. The occurrence of this mineral is an indication as to the prevalence of arid climatic conditions during the deposition of the strata. E. T. W.

Copiapite in coal. WILLIAM J. MCCAUGHEY. Ohio State Univ. *Am. Mineral.* 3, 162-3(1918).—A specimen of fibrous melanterite in slate partings from a coal mine altered in the museum in the course of a year, becoming dull white and showing dotting with yellow particles. These agreed to a considerable extent with the mineral copiapite in optical properties, and on analysis proved to be that species. Several alleged occurrences of sulfur in coal proved to consist of the same mineral. E. T. W.

The mesosiderite-grahamite group of meteorites: with analyses of Vaca Muerta, Hainholz, Simondium, and Powder Mill Creek. G. T. PRIOR. *Mineral. Mag.* 18,

capable of depositing  $\text{CaCO}_3$  and silicates. It contains 15 mol. of water but 14 of these go off as the temp. is raised without a break in the dehydration curve, and are therefore "water of crystn.," while the last mol. (that present as OH) is driven off only at red heat. By the above graphic formulas it is implied that, although arrangement in crystals is based on geometrical rather than chem. relationships, formation in solns. of mols. with such structures led to the crystn. of the mineral in the first place. It is recommended that thaumasite be described chemically as: di-hydroxy-tricalcium carbon-silico-sulfate, crystg. with 14 mols.  $\text{H}_2\text{O}$  in the hexagonal system. In an abandoned mine near Hellertown, Pa., measurable crystals of wavellite were found. The  $n_s$ , are  $\alpha = 1.525$ ,  $\beta = 1.535$  and  $\gamma = 1.550$ , all  $\pm 0.005$ ; the sp. gr. = 2.325. Eight forms are recognized. The angles of the best developed form (121) are  $\phi = 41^\circ 45'$ ,  $\rho = 47^\circ 15'$ , whence the ratios are  $a:b:c = 0.564:1:0.404$ , differing slightly from accepted values. Analysis by Wynkoop on a small amt. gave  $\text{Al}_2\text{O}_3$  36.5,  $\text{P}_2\text{O}_5$  33.4, F (too low) 0.8,  $\text{H}_2\text{O}$  28.6,  $\text{SiO}_2$  1.1, sum, less O = F 0.3, 100.1%. This agrees with the Groth formula for the mineral, which differs from that adopted by Dana in allowing for the F and in recognizing the presence of an additional half mol. of  $\text{H}_2\text{O}$ . Written in expanded form this is  $3\text{Al}_2\text{O}_3 \cdot 2\text{P}_2\text{O}_5 \cdot 13(\text{H}_2\text{O}, 2\text{HF})$ . L. W. RIGGS.

**Ore testing.** W. B. TIMM AND C. S. PARSONS. Canada Dept. Mines, *Summary Rept.* 1917, No. 493, 63-94(1918).—This is a rept. of the testing of the following ores: Au, 2 sandstones, garnet, 4 molybdenites, W, 3 manganese, Fe, Ag, Pb, 4 chromites, and ferromolybdenum. A description of the sample, its analysis, the method and description of the treatment and conclusions drawn therefrom are given.

R. L. SIBLEY.

**Investigation of iron ores.** A. H. A. ROBINSON. Canada Dept. Mines, *Summary Rept.* 1917, No. 493, 11-23(1918).—This report is the result of an investigation of occurrences of Fe ore in Ontario. These ore deposits are for the most part titaniferous magnetites of igneous origin and derived from the magma by a process of segregation. Analyses of a large number of samples show the following results: Fe 40-50,  $\text{TiO}_2$  10-27.5,  $\text{Al}_2\text{O}_3$  2.8, CaO 1, MgO 2,  $\text{SiO}_2$  5, and P less than 0.02%; S low, with V sometimes present. It is evident that the Ti content is too high to permit the use of the Fe ores in the blast furnace, while it is too low to be regarded as a source of Ti. This Fe-bearing belt has been traced for a distance of 14 miles.

R. L. SIBLEY.

**Indian River copper deposits, Vancouver mining division.** CHARLES CAMSELL. Canada Dept. Mines, Geol. Survey, *Summary Rept.* 1917 (Pt. B), 23-5(1918).—The deposits of this region all contain Cu as the principal valuable metal; it occurs as chalcopyrite, associated with pyrite and  $\text{ZnS}$ . Descriptions are given of 4 of the groups of claims. Assays of several samples of the ore average about 3% Cu with some Ag and Au.

R. L. SIBLEY.

**Explorations in Yukon Territory.** W. E. COCKFIELD. Canada Dept. Mines, Geol. Survey, *Summary Rept.* for 1917 (Pt. B), 1-9(1918).—Placer Au is the only mineral of economic value at present being produced in the Sixty-mile district. Its distribution in the gravels of the river is exceedingly widespread, but the deposits are not rich enough to work extensively. The pay-streak is nowhere very rich, and in some places runs as low as 5 to 9 cents a square foot. No W was found in any of the gravels examd.

R. L. SIBLEY.

**Economic geology of the Hazelton district.** B. C. J. J. O'NEILL. Canada Dept. Mines, Geol. Survey, *Summary Rept.* 1917 (Pt. B), 9-12(1918).—There are several important Ag-Pb-Zn deposits in this district which are briefly described. Most of the deposits are of such small Ag and Au content that they cannot be profitably worked under present conditions.

R. L. SIBLEY.

**Reconnaissance along the Pacific Great Eastern railway between Squamish and Lillooet.** C. CAMSELL. Canada Dept. Mines, Geol. Survey, *Summary Rept.* 1917 (Pt. B), 12-23(1918).—The geology of this portion of the western part of British Columbia is given. It was found that large bands of sedimentary and other stratified rocks lie in what was supposed to be a mass of granodiorite, thus giving conditions most favorable for the occurrence of deposits of Cu, Pb, Zn, Au and Ag. No important developments have yet been made and prospectors are urged to pay more attention to the possibilities of the coast mountains. Some small Au, Ag, and Cu deposits, Fe ore, talc and clay are briefly described.

R. L. SIBLEY.

**Investigations in the Slocan district,** B. C. M. F. BANCROFT. Canada Dept. Mines Geol. Survey, *Summary Rept.* 1917 (Pt. B), 28-41(1918).—This district includes the area in British Columbia which leads in the annual Ag production of the Province. A primary deposit of rhodonite ( $\text{MnSiO}_3$ ) is described. A secondary deposit is also mentioned. This consists of different forms of wad or bog Mn (variable,  $\text{H}_2\text{MnO}_4$ ). A sample proved to be a very good grade of wad, containing 48.14% Mn and 1.65% Fe and varying amts. of organic matter. A study of the distribution and character of the wad deposits showed them to have been formed by the deposition from mineral springs in swampy ground with little drainage. Other metals also obtained from the ores of this district are Au, Ag, Pb, Zn, Cu and Sb. Different deposits of these various metals are briefly described. Very little prospecting or mining development has been done in this district.

R. L. SIBLEY.

**Note on the occurrence of diatomaceous earth, clay and magnesite along the route of the Pacific Great Eastern Railway.** CHARLES CAMSELL. Canada Dept. Mines, Geol. Survey, *Summary Rept.* 1917 (Pt. B), 25-8(1918).—A magnesite deposit which occurs in short narrow veins is described. A sample was found to contain 70  $\text{MgCO}_3$ , 27  $\text{CaCO}_3$  and 2% Fe. The material was not affected by heat up to 1600° C., but contains too much Ca to be of commercial use. Some clay beds are also described, and a deposit of diatomaceous earth which overlies one of them. It is white or grayish, very light and will float before it absorbs water. Analysis showed  $\text{SiO}_2$  76.2, loss on ignition 10.8, and residue 13.0%. This material can be used for the manufacture of insulating brick when mixed with 20% of clay and some sawdust and burned.

R. L. SIBLEY.

**Limestones of Ontario.** HOWELLS FRÉCHETTE. Canada Dept. Mines, *Summary Rept.* 1917, No. 493, 23-48(1918).—A total of 126 analyses of samples of limestone are reported as to their content of insol. mineral matter,  $\text{Fe}_2\text{O}_3$ ,  $\text{Al}_2\text{O}_3$ ,  $\text{CaCO}_3$ ,  $\text{MgCO}_3$ , CaO equiv., and MgO equiv. These samples were collected from different quarries in the various counties of Ontario. A sample of marl was tested without previous laboratory grinding and gave 35.1% fine whiting, and 43.9% of coarse whiting, both of which are of a fineness suitable for commercial use. Most of the marls dry to a light cream color, but some give an almost pure white product.

R. L. SIBLEY.

**Non-bituminous road materials.** L. REINECKE. *Econ. Geol.* 13, 557-97(1918).—This paper is intended as an introduction to the study of non-bituminous road materials and describes the field and lab. tests applied to bed rock, glacial boulder, and gravel deposits and the relative values of the tests in each division.

A. B. PECK.

**The basaltic rocks of the Arctic region.** ARTHUR HOLMES. *Analyses.* H. F. HARWOOD. *Mineral. Mag.* 18, 180-223(1918).—A petrographical and chem. investigation of the rocks of Hare Island, West Greenland; Scoresby Sound, East Greenland; Iceland, Faroe Islands, Jan Mayen, Spitzbergen, and Franz Josef Land. The rocks have approx. equal amts. of salic and femic minerals except in the porphyritic rocks of Scoresby Sound and Spitzbergen where salic dominates. Alkalies are subsidiary to

lime and of the alkalis soda is always predominant. The outstanding chem. features are low  $\text{SiO}_2$ ,  $\text{Al}_2\text{O}_3$ , and alkalis, and high  $\text{TiO}_2$ ,  $\text{Fe}_2\text{O}_3$ , and  $\text{CaO}$ .  $\text{V}_2\text{O}_5$  is present in greater amt. than  $\text{Cr}_2\text{O}_3$  and is probably a constituent of the pyroxenes.  $\text{TiO}_2$  is present mainly as ilmenite or titaniferous magnetite and to some extent in the pyroxenes of the saturated rocks. Among the saturated rocks those with porphyritic plagioclase contain less  $\text{TiO}_2$  than those without phenocrysts.  $\text{NiO}$ ,  $\text{Cr}_2\text{O}_3$ , and  $\text{V}_2\text{O}_5$  were estd. in one sample by the following method: 5 g. were treated in Pt dish with  $\text{H}_2\text{SO}_4$  and  $\text{HF}$  and evapd. until the  $\text{H}_2\text{SO}_4$  fumed strongly; digested with hot  $\text{H}_2\text{O}$  and filtered. The residue was ignited, fused with  $\text{Na}_2\text{CO}_3$ , and the melt dissolved in dil.  $\text{H}_2\text{SO}_4$  and added to the previous soln. Br water was added to oxidize Fe and the excess removed by boiling;  $\text{NH}_4\text{OH}$  was added, and both Cr and V pptd. The combined ppt. was fused in a Ni crucible with  $\text{NaOH}$  and  $\text{Na}_2\text{O}_2$ , the melt extracted with  $\text{H}_2\text{O}$  and the V and Cr estd. by Hillebrand's method (pptn. with  $\text{HgNO}_3$ ). The Ni is estd. in the filtrate with dimethylglyoxime.

WALTER F. HUNT.

Silicate specific heats (WHITE) 2.

## 9. METALLURGY AND METALLOGRAPHY.

WILLIAM BRADY, WILLIAM T. HALL.

Why minerals float. GEO. J. YOUNG. *Eng. Mining J.* 106, 1127-8(1918).—The formation of a froth is due to conditions which permit flocculation, to the occlusion (adsorption) of O by both the mineral particles and the oily particles, and to the presence of an oily substance in which there is a colloidal suspension. The adsorption of O by the sulfide minerals and the oil is due to the fact that they are oxidizable substances. Flocculation may be brought about by the use of suitable electrolytes, by heat or by discharge of charged particles in suspension.

E. SCHRAMM.

Collective and preferential flotation. GUY C. RIDDELL. *Chem. Met. Eng.* 19, 822-5(1918).—The use is described of the Bradford  $\text{SO}_2$  process at the slimes plant of the Broken Hill Proprietary Co. in Australia. A notable feature of the operation at this plant is that no oil or other org. emulsifying agent is employed. Experience at Broken Hill has demonstrated the desirability of violent agitation for the Bradford process. It is pointed out that the difference between the Bradford process and other preferential processes is that it effects a positive wetting of the blende, i. e., a removal of the gaseous envelope. The advantages of lab. control are emphasized and the points to be particularly watched are enumerated.

E. SCHRAMM.

Annual review on the various metals, metal products, ores and other minerals for 1918. *Eng. Mining J.* 107, No. 2(1919) cf. C. A. 12, 464.—This whole number (96 pp.) is devoted to statistics by various authors relating to production, trade, prices, mining, etc. The field is covered with considerable thoroughness. A few of the reviews of a bit more chem. interest than the others are: "Lead products other than white lead," by J. R. WERTSTEIN; "New mining and metallurgical construction in 1918;" "The tungsten industry in 1918," by GEO. J. YOUNG; "Ferro-alloys in 1918," by ROBERT J. ANDERSON; "Metallurgy of quicksilver," by MURRAY INNES; "Metallurgy of zinc," by W. R. INGALLS; "Metallurgy of lead," by H. O. HOFMAN; "Metallurgy of copper," by ARTHUR L. WALKER; "Metallurgy of gold and silver," by A. W. ALLEN; "The flotation process," by A. W. ALLEN; "Notes on ore dressing," by A. W. ALLEN; "Uncommon ores and metals," by H. C. MEYER; and "Pyrite, sulfur and sulfuric acid."

E. J. C.

Copper, lead, gold and silver ores. C. H. FULTON. *Metal Record and Electro-Plater* 4, 274-6(1918).—A review.

C. G. F.

**Molybdenum within the (British) Empire.** SYDNEY J. JOHNSTONE. *J. Soc. Chem. Ind.* 37, 448-50R(1918). E. H.

**Powdered coal for igniting D. and L. roasters.** ANON. *Chem. Met. Eng.* 19, 797(1918).—An app. is described which has been successfully tried at the Midvale Smelter of the United States Smelting, Refining and Mining Co. E. SCHRAMM.

**Melting the non-ferrous metals.** CARL HERRING. *Metal Record and Electroplater* 4, 271-2(1918).—See C. A. II, 2070. C. G. F.

**Unique features of an Illinois foundry.** CHARLES LUNDBERG. *Iron Age* 102, 1563-9(1918).—A description of practice at the foundry of the Avery Co., Peoria, Ill., including operation of a  $1\frac{1}{2}$ -ton Booth-Hall elec. furnace. In the latter it has been found best to carry the magnesite lining to the roof. Shank ladles into which the metal is tapped are brought almost to a white heat by an oil heater, giving a clean pour. The foundry is continuously operated and is designed for large production in small space. In the molding room molds are made on machines at the outer edge of a circle, and then pushed toward the center and out of the way of the molder. The circle thus used accommodates 60-70 molds. A. BUTTS.

**Removing foundry dust by electrical precipitation.** H. D. EGBERT. *Foundry* 47, 43-5(1919).—E. describes an application of the Cottrell process of elec. pptn. to the treatment of dusty air from tumbling barrels in an iron foundry. The recent tendency in elec. pptn. work is to collect electrode tubes of smaller diam. to obtain better efficiency with a lower operating voltage. To secure uniform distribution of the dusty air among the collecting electrode pipes the air is admitted some distance above the bottom of the pipes so that it passes down around these, then up between the electrodes, thence to the top header and to the open air. The precipitator consists of three sections, each with 36 collecting electrode pipes 8 in. in diam. by 15 ft. long. One set of elec. equipment furnishes the current for all three pptg. sections. Advantages claimed for the process are: satisfactory collection of dust; elimination of danger of fire by sheet metal construction, when necessary; and ability to treat the gases at any temp. up to 538°. W. H. BOYNTON.

**A small open-hearth furnace.** EDWIN BOSSHARDT. *Iron Age* 102, 1458(1918).—The furnace is of German design. It is of 2 metric tons' capacity, and is fired by two producers of the Siemens type built as a part of the furnace (one at each end). There are gas and air regenerators; and the reversing valves are so constructed that the gas from the producer at the exit end is passed over to the inlet port at the other end. It is claimed that a temperature of 2000° is reached. It is used for making steel castings from scrap. The fuel consumption claimed is 1 lb. coal per lb. scrap when melting 2 charges per day; or  $\frac{1}{2}$  lb. coal on 4 charges per day. W. L. BADOER.

**Manganese-alloy furnaces.** P. H. ROYSTER. *Iron Age* 102, 1607(1918).—Poor quality of coke used for blast furnaces producing ferro-Mn and spiegeleisen causes serious waste of both Mn and coke. Since the principal loss of Mn is due to the slag and is roughly proportional to the vol. of the slag, a low-ash coke is required. Figures are given, based on the actual statistics of the Mn industry, showing that there would be an enormous saving if coke with 8% ash were allocated to the Mn-alloy furnaces; and also that there would not be a corresponding handicap to the production of pig Fe, except that more furnace capacity would be needed. A. BUTTS.

**Effective tube-mill liners.** A. W. ALLEN. *Eng. Mining J.* 106, 867(1918).—An example of the difficulties met when liners do not fit closely the surface they are supposed to protect. A tube mill with dished heads was provided with flat head liners and cylindrical trunnion liners, meeting in a sharp right angle and leaving considerable space between the flat liner and the dished head. The angle where the trunnion liner

met the head liner soon wore off, sand entered the space, and finally resulted in failure and collapse of the mill. New liners were made with a smooth rounded throat opening into the trunnion, making a smooth joint with the trunnion liners. The dead space behind the liners was filled with tightly fitted wood blocks, which swelled to fill the space tightly. This arrangement was extremely satisfactory. W. L. BADGER.

**The Berdan pan for amalgamation.** A. W. ALLEN. *Eng. Mining J.* 106, 1075-6 (1918).—The pan is a circular cast-Fe trough turning with a revolving shaft at its center at a speed of 10-5 r. p. m. It is tilted so that material fed in will flow out gradually at the lower part of the lip. The trough contains a 120-lb. steel ball, which rolls in a pool of Hg. Fine ore revolving under the ball is ground and amalgamated. The pan has too small a capacity for use as a unit of milling equipment, but is effective and simple for small operations, clean-ups, and many special uses. It requires very little power. The Hg is not floured. A. BUTTS.

**Zinc-box practice.** A. W. ALLEN. *Eng. Mining J.* 106, 1017-21 (1918).—Due to fluctuation in the grade of cyanide soln., automatic feed adjustment in the addition of a precipitant is ordinarily impracticable; the precipitant must be added in excess to avoid danger of imperfect pptn. When a base metal is used as the precipitant, excess fouls the ppt. and it may be necessary to introduce a refining plant to remove the excess from it. This is not justified in the smaller plants, and the use of Zn shavings has the advantage over dust in that the shavings can be screened off. A combination of dust for the bulk of the pptn. and shavings for the finishing can be used. With Ag cyanidation coarse shavings,  $\frac{1}{400}$  in. thick, can be used and returned to the Zn boxes after screening off. With Au  $\frac{1}{750}$ -in. shaving is better, and the excess is roasted or acid-treated. Cloudy soln. is a source of trouble; it should be clarified by a press required to handle only the finest material. Extra Zn boxes over the required capacity will simplify operation and clean-up. When the barren soln. begins to gain in metal content an additional box may be packed with Zn; addition of boxes in this manner avoids much dressing. Fresh Zn should not be added in the first compartment before the clean-up, but the attacking action of the soln. should be concentrated there on short Zn and the sludge removed in a concentrated form. Boxes with level bottoms, no means of drainage, or inaccessible parts, are to be avoided. Suggestions for the clean-up are given, and also methods of computing the rate of flow of soln. through the boxes, which must be carefully regulated to save both cyanide and Zn.

A. BUTTS.

**Innovations in the metallurgy of lead.** DORSEY A. LYON AND OLIVER C. RALSTON. *Bur. of Mines, Bull.* 157, 169pp. (1918).—The application of new hydrometallurgical and other methods has been made to the following ore types, (a) oxidized lead ores, (b) oxidized lead ores containing precious metals, (c) oxidized Pb and Zn ores, (d) simple sulfide ores of Pb, (e) leady Zn concentrates, (f) Pb-Fe sulfide middlings, (g) complex sulfide ores of Pb, Zn, Fe and Cu with or without precious metals. Three alternative methods have been tested in treatment of material containing oxidized Pb, as follows: sulfidizing and flotation, acid brine leaching of the raw material, and volatilization of the Pb with the recovery of the lead chloride fume. For the non-oxidized ores of Pb the Pb may be removed by chloridizing roasting with volatilization or subsequent leaching. E. SCHRAMM.

**Reconstruction in the zinc industry.** J. A. SINGMASTER. *J. Ind. Eng. Chem.* 11, 146-7 (1919).—It is believed that "the chief role of chem. and phys. science in this period of reconstruction will be along quality lines." E. J. C.

**The elimination of gelatinous silica in the hydrometallurgy of zinc.** F. LAIST. *Eng. Mining J.* 106, 1117-8 (1918).—The silica is pptd. in the presence of ore pulp by

addition of calcine, limestone and zinc duct and filtered but not washed. It is then dried at about 150°. This primary filter cake is leached with acidified soln. and the resulting pulp filtered, leaving a granular silica residue which is comparatively free from zinc.

E. SCHRAMM.

Condensing quicksilver from furnace gases. L. H. DUSCHAK AND C. N. SCHURTER. *Mining Sci. Press* 117, 315-23; *Bur. of Mines Tech. Paper* 209.—Investigations were made of the amt. of Hg escaping from the condenser systems at the New Idria and the Oceanic mines in California, the work being conducted through the Bur. of Mines Expt. Station at Berkeley. The plants have Scott furnaces followed by brick condensers, then wooden tanks, barrels, and flues leading to the stacks. The gases contain a large amt. of water-mist. Samples were withdrawn through a glass tube 0.15 in. inside diam. and drawn through a Liebig condenser, a water-cooled bead-tower, a Hawley filter, a wash-bottle containing NaOH for removal of CO<sub>2</sub> and SO<sub>2</sub>, and a small gas-meter. Aspiration was by a water-jet pump. Samples were of 100-500 l. Gas velocity in the flues was detd. by injecting H<sub>2</sub>S at the lower end and detecting its appearance at the end of a measured length by drawing a sample of the gas through Pb(OAc)<sub>2</sub> soln. This detn. of gas vol. checked the vol. as calcd. from the furnace C-consumption and the gas CO<sub>2</sub>-content. To the amt. of condensed Hg collected there was added a correction for uncondensed vapor as calcd. from the vapor tension of Hg at the mean temp. of the Liebig condenser and the bead-tower. Results showed a total loss of 0.04 to 0.12 g. of Hg per cu. m. of dry gas at standard conditions, or 1% of the Hg input at the New Idria and 2% at the Oceanic. Water escaping from a condenser system carries Hg either as metallic particles or as salts in soln. Other sources of loss are by gas leakage in case of insufficient draft, by absorption into the walls, and mechanical losses from leaks and spattering. A slight in-draft should be present in all parts of the system to avoid danger of serious loss. These latter sources of loss, which cannot be measured, are usually large; the measured losses are small. The larger losses can be avoided, so that a condenser efficiency of at least 96-9% should be attained.

A. BUTTS.

Metallography of aluminium. ROBERT J. ANDERSON. *J. Franklin Inst.* 187, 1-47(1919).—Sections are devoted to: The amorphous theory and plastic deformation, observations on grain growth phenomena, internal structure of cast Al, annealing and recrystallization of cold-worked Al, exaggerated grain growth in deformed Al, slip bands in Al, polishing and etching Al, bibliography (61 references cited).

JOSEPH S. HEPBURN.

Annealing aluminium. ANON. *J. Ind. Eng. Chem.* 11, 155(1919).—Prolonged annealings are harmful, rendering the metal coarse and weak. The results of tests show that there is no necessity for annealing at 375° for 24 hrs., as is common practice.

W. T. H.

A study of the joining of metals. J. A. CAPP. *Gen. Elec. Rev.* 21, 947-56(1918).—A report of an investigation of the metallurgical aspect of butt welding and the effect of (1) high current applied for a relatively long time, (2) a smaller current applied for a shorter time and (3) a current just high enough to produce a welding temp. in a minimum length of time. A complete set of micrographs shows conclusively that the degree of excellence of the weld increases with the current condition in the order given. Welds may be made by the Thompson process, so that the metal is structurally the same in the weld as in the areas away from the influence of the weld. The conditions under which such results may be obtained are that the surfaces in contact and the metal in the immediate vicinity be heated no higher than in ordinary forge welding. The time should be brief and the pressure enough to force contact and very slight deformation. Welds made under conditions favoring a heavy "flash" are unreliable and

of necessity weaker than the original metal, since a flash is accompanied by decarbonization and blowholes. W. E. RUDER.

Lead, tin and antimony alloys. O. W. ELLIS. *Metal Record and Electroplater* 4, 277-81(1918).—See C. A. 12, 1285. C. G. F.

Cupro-nickel. T. H. A. EASTICK. *Metal Ind.* 17, 26-8(1919).—The equilibrium diagram, the physical properties, structure and metallographic characteristics of Cu-Ni alloys are described. W. T. HALL.

An example of crystal crushing. ANON. *Chem. Met. Eng.* 20, 72(1919).—After a tensile strength test of shell steel, the fractured surface shows a crystalline structure except at about the center which often has a silky appearance. This appears to be due to a crushing of crystals during the stretching of the bar before rupture.

W. T. H.

The value of observation in works practice. H. H. ASHDOWN. *Engineering* 107, 11-4(1919).—Habits of observation, such as we attempt to teach students of chemistry, are shown to be of value in practical work with metals. The value of proper correlation between scientific and practical work is urged. W. T. H.

Micro-metallographic illumination. HENRY M. SAWYER. *Engineering* 106, 729-30(1919).—The methods of illumination for microscopic work with metals are discussed and tests described for obtaining the best results. W. T. H.

The inspector's standpoint in munition production. JOHN T. MARSH. *J. Cleveland Eng. Soc.* 11, 131-52(1918).—Actual observations on materials from which munitions of war were to be made are described. Whether defective material, such as an ingot of steel, is the result of blundering, ignorance, criminal negligence or intentional criminal action cannot be detd. Among other examples, the results of a premature explosion in a 4.5 howitzer gun are shown. The value of the defective shell which caused terrific damage, at a stage where its weakness could have been detected, was only \$2. This case is cited to show that the value of rejected material is something that an inspector cannot take into consideration. W. T. HALL.

The occlusion of gases in metals. ANON. *Nature* 102, 234(1918).—A digest of a symposium held at the Faraday Society on the occlusion of gases in steel, Ag, Cu and other metals. Cf. C. A. 13, 220. W. H. ROSS.

On the rate of change at 100° and at ordinary temperatures in the electrical resistance of hardened steels. E. D. CAMPBELL. *Electrician* 82, 17-8(1919).—See C. A. 12, 129, 268. C. G. F.

Concentrating ores. O. WISER. U. S. 1,288,350, Dec. 17. Ores which may contain Cu, Zn or other metals, are subjected to a flotation sepn. in a bath containing H<sub>2</sub>O, Na resinate and oil. Na<sub>2</sub>S may also be added to facilitate sepn. of mixed Cu ores.

Reducing ores containing iron and manganese. J. T. JONES. U. S. 1,288,422, Dec. 17. An ore containing Fe and Mn, pulverized to 20-100 mesh, is mixed with coal pulverized to the same fineness and the mixt. is heated out of contact with air to about 1100° to coke the coal and reduce the Fe to metal. The reduced Fe is sepd. from the

coked material and the residue is then heated to about 1650° in the presence of air to reduce the Mn to metal.

**Treating gold ores.** J. PENHALE and W. H. TRELOAR. Brit. 120,287, Dec. 3, 1917. Au ores are freed from sulfides of Sn and As by crushing and sliming in an aq. soln. of alkali metal sulfides. After filtration, the Sb and As sulfides may be pptd. from the resulting soln. by means of acid.

**Treatment of zinciferous ores.** P. M. GILLIES. Can. 188,033, Dec. 31, 1918. Complex sulfide ores are treated after roasting and crushing with  $H_2SO_4$  to dissolve the ZnO, the  $ZnSO_4$  soln. is then purified with  $H_2S$  and electrolyzed.

**Continuous isolation of zinc or lead.** E. A. JOHANSSON. Swed. 44,072, May 22, 1918. The ore is treated successively in two communicating furnaces arranged in such manner that only the fused charge can pass through the communicating channel. In the first furnace the charge is fused and purified, with the addition of fluxes if necessary, while the reduction is effected in the second furnace.

**Extracting copper from ores.** H. W. MORSE. U. S. 1,288,121, Dec. 17. Ore containing cuprite together with other oxidized Cu minerals and Cu sulfide is treated with dil.  $H_2SO_4$  to sep. part of the Cu of the cuprite as metallic Cu and to dissolve another part of the cuprite together with Cu of the other minerals present. The resulting pulp is subjected to flotation to sep. the metallic Cu and sulfide values from it and the dissolved Cu is then pptd. *e. g.*, by the action of scrap Fe, and the metallic Cu and remaining Cu sulfide is then recovered from the resulting pulp by flotation.

**Recovery of metals from slags.** J. B. HERRESHOFF. Brit. 117,470, Apr. 14, 1917. See Can. 181,246 (C. A. 12, 578).

**Refining zinc.** S. HULDT. Can. 188,176, Jan. 7, 1919. Zn containing Pb is refined by providing a molten bath having a vaporizing surface properly proportioned to its depth so that the Pb will not be vaporized. The bath constitutes a heat magazine for counterbalancing variations of temp.

**Refining zinc.** G. C. FRICKER. U. S. 1,287,949, Dec. 17. Vapor from impure Zn is passed through a filter of foundry coke or other inert material which is so placed as to float upon the charge of molten Zn undergoing refining and completely to cover its surface. The coke retains impurities and thus separates them from the Zn.

**Smelting furnaces or cupolas.** A. POULSON. Can. 188,472, Jan. 28, 1919. The furnace comprizes a chamber surrounding the cupola, a series of tuyère holes leading from the chamber tangentially into the furnace and a jacket surrounding the blast inlet to the chamber, to which jacket a portion of the hot gases from the cupola is led.

**Rust-proofing iron or steel.** W. H. ALLEN. U. S. 1,287,605, Dec. 17. A soln. for treating Fe or steel to prevent rust is formed of  $Na_2Cr_2O_7$ ,  $H_3PO_4$  and  $H_2O$ . Other chromates or dichromates or manganates or permanganates may also be used.

**Chrome-steel.** C. H. WILLS. U. S. 1,288,344, Dec. 17. A case-hardening steel is formed of the usual constituents with the addition of about 1% or less of Mo which renders it possible to accomplish refining of the case and core simultaneously. The steel may, *e. g.*, contain C 0.06–0.18%, Mn 0.20–0.75%, Cr 0.75%, Si 0.10–0.40% and Mo 1% or less.

**Spring-steel.** C. H. WILLS. U. S. 1,288,345, Dec. 17. A "heavy-duty" spring steel is formed containing C 0.38–0.55%, Mn 0.40–1.25%, Cr 2% or less, Si 0.10–0.40% and Mo 1% or less. The steel preferably is drawn at a temp. of about 570°.

**Utilizing sulfuric acid pickle liquors.** P. FIREMAN. U. S. 1,287,939, Dec. 17. The free  $H_2SO_4$  in pickle liquor such as has been used for pickling Fe or steel is neutralized with scrap Fe or CaO, the resultant  $FeSO_4$  soln. is treated with  $CaCl_2$  and the

$\text{FeCl}_3$  soln. so obtained (after removal from the ppt. of  $\text{CaSO}_4$ ) is treated with  $\text{Ca}(\text{OH})_2$  to regenerate the  $\text{CaCl}_2$  and produce a ppt. of  $\text{Fe}(\text{OH})_3$ .

**Composition for making follow boards and patterns used in founding.** F. S. KNAPPER. U. S. 1,288,035, Dec. 17. A mixt. for making patterns is formed of sand 50, cement 3, graphite 3,  $\text{PbO}$  1 part and sufficient linseed oil or other vegetable oil to form a plastic mass. Patterns formed of this material are preferably coated with shellac.

**Crude cyanides.** HORACE FREEMAN. Can. 188,258, Jan. 14, 1919. A compn. containing 20% of an alkali metal cyanide mixed with an alkali metal chloride, an alk. earth chloride,  $\text{CaO}$  and  $\text{C}$  is used in the extn. of  $\text{Au}$  from its ores.

**Phosphorus-copper alloy.** P. E. DEMMLER. U. S. 1,287,653, Dec. 17.  $\text{Cu}$  is heated to a temp. somewhat below its m. p., preferably about  $400^\circ$ , and vapors of  $\text{P}$  are then allowed to combine with it.  $\text{P}$  and  $\text{Zn}$  or  $\text{Sn}$  may be similarly combined.

## 10. ORGANIC CHEMISTRY.

CHAS. A. ROUILLER.

**Polyhydric mercaptans of the benzene series.** VI. Homologous dithiolbenzenes. J. POLLAK AND B. SCHADLER. *Monatsh.* 39, 129-48 (1918); *J. Chem. Soc.* 114, I, 497-8. —By treatment with fuming  $\text{H}_2\text{SO}_4$ , *m*-xylene was converted into a mixture of disulfonic acids, from which by the action of  $\text{PCl}_5$  a mixt. of the corresponding *m*-xylene-2,4- and -2,5-disulfonyl chlorides was obtained. The cryst. 2,4-chloride, on reduction with  $\text{Sn}$  and  $\text{HCl}$ , gave 2,4-dithiol-*m*-xylene,  $\text{C}_6\text{H}_2\text{Me}_2(\text{SH})_2$ , leaflets, m.  $123-5^\circ$  (acetyl derivative,  $\text{C}_6\text{H}_2\text{Me}_2(\text{SAc})_2$ , leaflets, m.  $76.5-79^\circ$ ), which reacts with  $\text{ClCH}_2\text{CO}_2\text{H}$  and  $\text{ClCO}_2\text{Et}$ , resp., in alk. soln., yielding *m*-xylene-2,4-dithiolacetic acid,  $\text{C}_6\text{H}_2\text{Me}_2(\text{SCH}_2\text{CO}_2\text{H})_2$ , stellar aggregates, m.  $185-9^\circ$ , and 2,4-diethylthiocarbonato-*m*-xylene,  $\text{C}_6\text{H}_2\text{Me}_2(\text{SCO}_2\text{Et})_2$ , long needles, m.  $61-3^\circ$ , and is converted by aq.  $\text{H}_2\text{O}_2$  into a substance,  $(\text{C}_6\text{H}_2\text{Me}_2\text{S}_2)_n$ , needles, m.  $252-5^\circ$ ; with picryl chloride the mercaptan reacts, producing 2,4-dipicrylthiol-*m*-xylene,  $\text{C}_6\text{H}_2\text{Me}_2[\text{SC}_6\text{H}_2(\text{NO}_2)_3]_2$ , orange needles with 1  $\text{C}_6\text{H}_4$ , m.  $258-9.5^\circ$ . Treatment with  $\text{Me}_2\text{SO}_4$  in the presence of alkali converts the mercaptan into 2,4-dimethylthiol-*m*-xylene,  $\text{C}_6\text{H}_2\text{Me}_2(\text{SMe})_2$ , needles, m.  $83-84.5^\circ$ , which reacts with  $\text{Cl}$ , yielding a substance  $\text{C}_{10}\text{H}_{11}\text{S}_2\text{Cl}$  and with  $\text{Br}$  in  $\text{CHCl}_3$  soln., giving an additive compound,  $\text{C}_6\text{H}_2\text{Me}_2(\text{SMe})_2\text{Br}_2$ , deep red needles, decomp.  $99-102^\circ$ ; this regenerates the parent substance when shaken with aq.  $\text{NaHSO}_3$  in  $\text{CHCl}_3$ . Oxidation with aq.  $\text{KMnO}_4$  converts the di-Me deriv. into the disulfone,  $\text{C}_6\text{H}_2\text{Me}_2(\text{SO}_2\text{Me})_2$ , needles, m.  $187-8^\circ$ . In a similar manner, the isomeric oily 1,3,2,5- $\text{C}_6\text{H}_2\text{Me}_2(\text{SO}_2\text{Cl})_2$  can be reduced to an oily 2,5-dithiol-*m*-xylene, b.  $142-4^\circ$ , which reacts with  $\text{ClCH}_2\text{CO}_2\text{H}$  in alk. soln., giving *m*-xylene-2,5-dithiolacetic acid, stellar aggregates, m.  $158-61^\circ$ , and with picryl chloride forming 2,5-dipicrylthiol-*m*-xylene, crystals, m.  $211-3^\circ$ . The 2,5-dimethylthiol-*m*-xylene, b.  $167-9^\circ$ , obtained by methylation with  $\text{Me}_2\text{SO}_4$ , undergoes substitution when treated with  $\text{Br}$  in  $\text{CHCl}_3$ , yielding a bromo derivative,  $\text{Me}_2\text{C}_6\text{H}_2\text{Br}(\text{SMe})_2$ , cryst. scales, m.  $122-3^\circ$ . The unexpected greater ease of bromination of this compd. led to a doubt as to whether the relative structures of these substances are really as assumed above, but an attempt to decide this matter by heating the 2,4-disulfonyl chloride with  $\text{SOCl}_2$  in the hope of replacing the  $-\text{SO}_2\text{Cl}$  groups by  $\text{Cl}$  atoms was unsuccessful, the product being a substance,  $\text{C}_6\text{H}_2\text{O}_2\text{Cl}_4$ , cryst. scales, m.  $76-7^\circ$ , possibly 2,4,1,3- $\text{C}_6\text{H}_2\text{Cl}_4(\text{COCl})_2$ . A somewhat similar reaction to this was observed between 1,3,4,6- $\text{C}_6\text{H}_2(\text{OMe})_2(\text{SO}_2\text{Cl})_2$  and  $\text{SOCl}_2$  at  $170^\circ$ , the product being a substance,  $\text{C}_6\text{H}_2\text{O}_2\text{Cl}_4$ , needles, m.  $95-8^\circ$ , possibly of the structure  $\text{C}_6\text{H}_2\text{Cl}_4(\text{OCH}_2\text{Cl})_2$ , 2,6(?)-Dithiol-*p*-xylene, b.  $145.5^\circ$  (diacetyl derivative, needles, m.  $79.5-82.5^\circ$ ; *p*-xylene-

2,6-dithiolacetic acid, needles, m. 170.5–4.5°; *picryl derivative* yellow cryst. solid, m. 251–5°; *dimethyl derivative*, needles, m. 92–4°) is obtainable from *p*-xylene through the disulfonyl chloride. VII. Substituted thiolbenzenes. *Ibid* 39, 179–200(1918); *J. Chem. Soc.* 114, I, 498–500.—The effect of the introduction of a Me group on the m. p. of the polyhydric mercaptans is rather irregular; thus, 1,3-dithiolbenzene and 2,4-dithiol-*m*-xylene, m. 25° and 121°, resp., whereas the substitution of a Me group into the nucleus of trithiolbenzene causes a small depression of the m. p. Further compds. were therefore prepd. with the view of investigating the influence of such substitution more widely, but no general regularities were observed either with the m. p. or b. p. 1-Ethylbenzene-2,4-disulfonic acid (barium salt, crystals with 2.5 mols. H<sub>2</sub>O), obtained by the action of fuming H<sub>2</sub>SO<sub>4</sub> on C<sub>6</sub>H<sub>5</sub>Et, was converted into the corresponding acid chloride C<sub>6</sub>H<sub>4</sub>Et(SO<sub>2</sub>Cl)<sub>2</sub>, by the action of PCl<sub>5</sub> on its sodium salt at 140–50°; the corresponding 1-ethylbenzene-2,4-disulfonamide, C<sub>6</sub>H<sub>4</sub>Et(SO<sub>2</sub>NH<sub>2</sub>)<sub>2</sub>, m. 186–90°, was obtained by the action of warm aq. NH<sub>3</sub> upon the chloride. On reduction with Sn and HCl, the acid chloride is converted into 2,4-dithiol-1-ethylbenzene, C<sub>6</sub>H<sub>4</sub>Et(SH)<sub>2</sub>, an oil, b<sub>15–20</sub> 150–2°, which reacts with alk. Me<sub>2</sub>SO<sub>4</sub>, yielding 2,4-dimethylthiol-1-ethylbenzene, C<sub>6</sub>H<sub>4</sub>Et(SMe)<sub>2</sub>, a pale yellow oil, b<sub>14</sub> 171–3°, while with ClCO<sub>2</sub>Et, and ClCO<sub>2</sub>Me in the presence of alkali the products are the colorless 2,4-diethylthiocarbonato-1-ethylbenzene, C<sub>6</sub>H<sub>4</sub>Et(SCO<sub>2</sub>Et)<sub>2</sub>, b<sub>14</sub> 224–6°, and the corresponding 2,4-dimethylthiocarbonato-1-ethylbenzene, b<sub>18</sub> 217–20°, resp. The dithiol compd. also reacts with ClCH<sub>2</sub>CO<sub>2</sub>H in the presence of alkali and with picryl chloride, yielding, resp., 1-ethylbenzene-2,4-dithiolacetic acid, crystals, m. 137–40°, and 2,4-dipicrylthiol-1-ethylbenzene, C<sub>6</sub>H<sub>4</sub>Et[SC<sub>6</sub>H<sub>3</sub>(NO<sub>2</sub>)<sub>3</sub>]<sub>2</sub>, yellow needles, m. 197.5–99°. When heated with AcONa and Ac<sub>2</sub>O, the dithiol compound is converted into the diacetyl derivative, b<sub>18</sub> 218–20°, and in the presence of alc. NH<sub>3</sub> is oxidized by concd. H<sub>2</sub>O<sub>2</sub> with the formation of the substance (C<sub>6</sub>H<sub>4</sub>EtS<sub>2</sub>)<sub>n</sub>. HNO<sub>3</sub> in the cold converts 2,4-(MeS)<sub>2</sub>C<sub>6</sub>H<sub>4</sub>Et into 5-nitro-2,4-dimethylthiol-1-ethylbenzene, NO<sub>2</sub>C<sub>6</sub>H<sub>3</sub>Et(SMe)<sub>2</sub>, yellow, silky needles, m. 117–8°, whereas fuming HNO<sub>3</sub> effects an oxidation to a monosulfoxide of the last product, NO<sub>2</sub>C<sub>6</sub>H<sub>3</sub>Et(SMe)SMeO, yellow, silky needles, m. 119.5–20.5°. In a similar manner to the preceding *p*-EtC<sub>6</sub>H<sub>4</sub>SO<sub>2</sub>Cl was made to yield 4-thiol-1-ethylbenzene, C<sub>6</sub>H<sub>4</sub>EtSH, b<sub>17–18</sub> 91–3° (acetyl derivative, C<sub>6</sub>H<sub>4</sub>EtSAC, b<sub>17–18</sub> 136.5–40°), which in alk. soln. reacts with ClCH<sub>2</sub>CO<sub>2</sub>H, giving 1-ethylbenzene-4-thiolacetic acid, C<sub>6</sub>H<sub>4</sub>EtSCH<sub>2</sub>CO<sub>2</sub>H, silky needles, m. 61–7°, and in alc. soln. with picryl chloride, forming 4-picrylthiol-1-ethylbenzene, deep yellow, silky needles, m. 113.5–6°. By treating phenol with fuming H<sub>2</sub>SO<sub>4</sub>, a mixt. of sulfonic acids can be obtained which, on conversion into the corresponding Na or K salts and heating with PCl<sub>5</sub> at 140–50°, yields a more sol. (in Et<sub>2</sub>O) 4-chlorobenzene-1,3-disulfonyl chloride, ClC<sub>6</sub>H<sub>3</sub>(SO<sub>2</sub>Cl)<sub>2</sub>, needles, m. 87–8°, and a less sol. 2-chlorobenzene-1,3,5-trisulfonyl chloride, C<sub>6</sub>H<sub>2</sub>Cl(SO<sub>2</sub>Cl)<sub>3</sub>, pale yellow needles, m. 170–1°. The former product, on reduction with Sn and HCl, gives 4-chloro-1,3-dithiolbenzene, C<sub>6</sub>H<sub>3</sub>Cl(SH)<sub>2</sub>, pale yellow liquid, b<sub>17–18</sub> 145–6° (acetyl derivative, C<sub>6</sub>H<sub>3</sub>Cl(SAC)<sub>2</sub>, b<sub>18</sub> 214–7°; picryl derivative, golden yellow platelets, m. 201–2°; dimethyl derivative, pale yellow oil, b<sub>18</sub> 177–9°); 4-chlorobenzene-1,3-dithiolacetic acid, C<sub>6</sub>H<sub>3</sub>Cl(SCH<sub>2</sub>CO<sub>2</sub>H)<sub>2</sub>, silky needles, m. 159–60°; the reaction with ClCO<sub>2</sub>Et followed an unusual course, the product under normal conditions consisting of 4-chloro-3(?)thiol-1(?)ethylthiocarbonato-benzene, HSC<sub>6</sub>H<sub>3</sub>ClSCO<sub>2</sub>Et, b<sub>18</sub> 204°, the completely substituted 4-chloro-1,3-diethylthiocarbonatobenzene, C<sub>6</sub>H<sub>3</sub>Cl(SCO<sub>2</sub>Et)<sub>2</sub>, needles, m. 48–9°, being obtained only with the use of an excess of ClCO<sub>2</sub>Et. The reduction of 2,1,3,5-C<sub>6</sub>H<sub>2</sub>Cl(SO<sub>2</sub>Cl)<sub>3</sub> gave 2-chloro-1,3,5-trithiolbenzene, yellow crystals, m. 64–67°; methyl derivative, C<sub>6</sub>H<sub>3</sub>Cl(SMe)<sub>3</sub>, needles, m. 92–4°; 2-chlorobenzene-1,3,5-trithiolacetic acid, needles, m. 199–200°.

C. J. WEST.

Tetramethyl-3,3'-diaminodiphenylmethane. ROLAND SCHOLL and JOS. LENKO. *Monatsh.* 39, 236–7(1918); *J. Chem. Soc.* 114, I, 506.—When heated with MeI and

MeOH at 140–50°, ( $m\text{-H}_2\text{NC}_6\text{H}_4$ )<sub>2</sub>CH<sub>2</sub> is converted into the *methiodide*,  $\text{C}_{16}\text{H}_{20}\text{N}_2\text{I}_2$ , needles, m. 165°, of *tetramethyl-3,3'-diaminodiphenylmethane*,  $\text{C}_{17}\text{H}_{20}\text{N}_2$ , the oily, free base being obtainable by heating the methiodide with soda-lime in an atm. of H or with concd. aq.  $\text{NH}_3$  in a sealed tube at 180–190°. C. J. WEST.

**Dihydrophenazine and dihydroacridine.** ROLAND SCHOLL AND W. NEUBERGER. *Monatsh.* 39, 238(1918); *J. Chem. Soc.* 114, I, 505.—Dihydrophenazine and dihydroacridine are formed when phenazine and acridine, resp., in hot alc. are gradually introduced into an aq.-alc. alk. soln. of  $\text{Na}_2\text{S}_2\text{O}_4$ . C. J. WEST.

**Phenylpropionamidine.** ROLAND SCHOLL AND E. BERTSCH. *Monatsh.* 39, 238–40(1918); *J. Chem. Soc.* 114, I, 495.—Phenylpropionamidine,  $\text{NH}:\text{C}(\text{Et})\text{NHPh}$ , m. 72–3°, is formed when EtCN is heated with  $\text{PhNH}_2\text{HCl}$  in a sealed tube at 170–80° for 12 hours; *hydrochloride*, hygroscopic; *hydrogen oxalate*, m. 141–2°; *picrate*, m. 152–3°. C. J. WEST.

**Acetyl cyanide.** ROLAND SCHOLL AND JOSEF ADLER. *Monatsh.* 39, 240(1918); *J. Chem. Soc.* 114, I, 482.—AcCN is conveniently prepd. by boiling a soln. of oximinoacetone in  $\text{CS}_2$  with a little more than the theoretical quantity of  $\text{P}_2\text{O}_5$  for 0.75 hr. and then distg.; the yield is approx. 40%. C. J. WEST.

**Dibromopyranthrone and attempts to prepare benzanthrone.** ROLAND SCHOLL. *Monatsh.* 39, 231–6(1918); *J. Chem. Soc.* 114, I, 484.—(With W. NEUBERGER). The substance obtained by the action of Br at 100° on pyranthrone is a *dibromo compound*,  $\text{C}_{20}\text{H}_{12}\text{O}_2\text{Br}_2$ . (With W. TRITSCH.) *2-Iodo-1-methylnaphthalene*,  $\text{C}_{11}\text{H}_9\text{I}$ , pearly, m. 51.5°, prepd. from 1,2- $\text{C}_{10}\text{H}_8\text{MeNH}_2$  by the diazo-reaction, when heated with finely pulverized Cu at 220–260° undergoes conversion into 1,1'-*dimethyl-2,2'-dinaphthyl*,  $\text{C}_{20}\text{H}_{18}$ , needles, m. 230°. The corresponding *dibenzyl-2,2'-dinaphthyl*,  $\text{C}_{24}\text{H}_{22}$ , and *di-p-chlorobenzyl-2,2'-dinaphthyl*, obtained by heating  $\text{PhCH}_2\text{Cl}$  and  $p\text{-ClC}_6\text{H}_4\text{CH}_2\text{Cl}$ , resp., with (2- $\text{C}_{10}\text{H}_7$ )<sub>2</sub> in the presence of  $\text{ZnCl}_2$ , were not pure substances. C. J. WEST.

**2-Methylantracene.** ROLAND SCHOLL. *Monatsh.* 39, 237–8(1918); *J. Chem. Soc.* 114, I, 484.—2-Methylantracene,  $\text{C}_{15}\text{H}_{12}$ , can be obtained by the action of HI and P on 2-methylantraquinone. C. J. WEST.

**Binuclear quinones. Chemical action of light.** HANS MEYER AND ALFRED ECKERT. *Monatsh.* 39, 241–51(1918); *J. Chem. Soc.* 114, II, 385–6.—Meyer and Hofmann have shown that dihydroanthracene, when heated, readily decomps. into anthracene and H, and it is therefore to be expected that the same dissociation should occur under the influence of light. Contrary to the statement of Orndorff and Cameron, this substance does undergo chem. alteration when exposed to light from the sun or elec. arc, the products being H and para-anthracene, the latter being formed by the immediate polymerization of the “nascent” anthracene, which is the primary product. In the presence of substances capable of reacting with this “nascent” anthracene, other products may be obtained. The action of light on anthracene probably also gives rise to “nascent” anthracene in which the diagonal valency becomes resolved into 2 free valencies. By these the formation of para-anthracene becomes possible. If O is present, the products are anthraquinone and dihydrodianthrone, the latter being formed by the further action of light on anthranol, which represents an intermediate stage of the change. It is already known that solns. of benzoquinone and thymoquinone in EtOH when subjected to light give rise to AcH and the corresponding quinol. With anthraquinone, however, the quinol deriv. is unstable, and in contact with air regenerates anthraquinone; it is therefore possible to use anthraquinone as a catalyst for the oxidation of EtOH to AcH in light, the only other product being a small quantity of an unidentified substance which gives a brown soln. in aq. KOH. In a similar manner iso-PrOH can be oxidized to acetone, but MeOH is very stable and is recovered

completely unchanged, together with the anthraquinone. This relative stability of MeOH accords well with the earlier results of Meyer and Hofmann and may account for the preponderance of Me derivs. among the naturally occurring alkyl compds. 9,10-Dichloro- and 9,10-dibromoanthracene are unaffected by light but 10-bromoanthracene in alc. gradually gives rise to anthraquinone and Br ions, together with a temporary small deposit of para-anthracene. If dihydroanthracene in  $\text{Ac}_2\text{O}$  is submitted to the action of light, the 1st deposit of para-anthracene may disappear on prolonged treatment, probably by further oxidation to anthraquinone. Anthranil acetate is obtained as a by-product, its formation supplying an explanation of the origin of dihydroanthracene in the action of light and air on anthracene in alc. soln. Solns. of anthracene in AcOH,  $\text{CHCl}_3$  and  $\text{Me}_2\text{SO}_4$ , when illuminated, give the same products; it was hoped with the aid of  $\text{Me}_2\text{SO}_4$  to isolate anthraquinol in the form of the di-Me ether, but unfortunately this compd. is sensitive to light and in AcOH is rapidly converted into anthraquinone.

C. J. WEST.

**Scoparin.** J. HERZIG AND GERTRUD TIEING. *Monatsh.* 39, 253-67(1918); *J. Chem. Soc.* 114, I, 503.—Goldschmiedt and von Hemmelmayr have shown that scoparin obtained from *Spartium scoparium* contains a MeO group and 6 HO radicals and attributed to the substance the formula  $\text{C}_{24}\text{H}_{30}\text{O}_{16}$ ; it was found possible to alkylate only 1 HO radical. By using  $\text{CH}_3\text{N}_3$ , however, it is possible to obtain a dimethyl derivative (trimethylnorscoparin),  $\text{C}_{24}\text{H}_{32}\text{O}_{12}$ , yellow crystals, m.  $260-5^\circ$  (decompn.), and a trimethyl derivative (tetramethylnorscoparin),  $\text{C}_{24}\text{H}_{34}\text{O}_{12}$ , yellow crystals, m.  $220-38^\circ$ , together with an amorphous substance. With MeI and  $\text{Ag}_2\text{O}$ , it is possible to convert scoparin into a cryst. octamethylnorscoparin,  $\text{C}_{24}\text{H}_{42}\text{O}_8(\text{OMe})_8$ , m.  $120-30^\circ$ , with subsequent resolidification and m.  $229-33^\circ$ . The compn. of these substances, as also that of acetylscoparin, renders it probable that the mol. formula of scoparin is not  $\text{C}_{20}\text{H}_{20}\text{O}_{16}$ , but  $\text{C}_{24}\text{H}_{30}\text{O}_{16}$ .

C. J. WEST.

**Eserine (physostigmine).** J. HERZIG AND HANS LIEB. *Monatsh.* 39, 285-92 (1918); *J. Chem. Soc.* 114, I, 504.—The ordinary method for detg. Me-N in eserine gives a result indicating the presence of 2 such groups, whereas the compd. obtained after the removal of 2 Me radicals, when examd. by the micro-method, shows the presence of a 3rd Me group; eseroline, when examd. by the micro-method, also gives results almost twice as high for Me-N as by the macro-method. This difference appears to be due to the larger proportion of HI used in the micro-method, and if in the macro-method only 0.1 g. of eserine is taken to 20 cc. HI, the result agrees with the presence of 3 Me-N groups. The reason of this peculiarity of eserine is at present undecided, although the possibility that the 3rd and resistant radical is an Et group, and not a Me, receives some support from the behavior of eserine when examd. by Kirpal and Bähm's method for Me detn.

C. J. WEST.

**Two new trihydric alcohols.** MORITZ KOHN AND VIKTOR NEUSTADTER. *Monatsh.* 39, 293-8(1918); *J. Chem. Soc.* 114, I, 477.—It has already been found possible by the action of  $\text{MeMgI}$  on the lactone of  $\text{Me}_3\text{C}(\text{OH})\text{CH}_2\text{CMe}(\text{OH})\text{CO}_2\text{H}$  to obtain  $\text{Me}_3\text{C}(\text{OH})\text{CH}_2\text{CMe}(\text{OH})\text{CMe}_2\text{OH}$ . Formisobutyraldol, by successive treatment with  $\text{NaHSO}_4$  and KCN, can be converted into the lactone of  $\text{CH}_2(\text{OH})\text{CMe}_2\text{CH}(\text{OH})\text{CO}_2\text{H}$ , b<sub>11</sub>  $118-20^\circ$ , b.  $237-41^\circ$ , which reacts with  $\text{MeMgI}$  to form  $\gamma, \alpha, \delta$ -trihydroxy- $\beta, \beta, \delta$ -trimethylpentane,  $\text{HOCH}_2\text{CMe}_2\text{CH}(\text{OH})\text{CMe}_2\text{OH}$ , b<sub>11</sub>  $152-5^\circ$ , b.  $256-262^\circ$ , which slowly solidifies to a cryst. mass, m.  $68-7^\circ$ . When heated with 33%  $\text{H}_2\text{SO}_4$ , this compd. yields a substance, probably 4-hydroxy-3,3,5,5-tetramethyltetrahydrofuran,  $\text{CMe}_2\text{O.CMe}_2\text{CMe}_2\text{CHOH}$ .

The action of  $\text{PhMgBr}$  on the lactone proceeds in an analogous manner, and yields  $\alpha, \gamma, \delta$ -trihydroxy- $\delta, \delta$ -diphenyl- $\beta, \beta$ -dimethylbutane, microscopic needles, m.  $130-3^\circ$ .

C. J. WEST.

The quinonoid oxidation product of methylenedi- $\beta$ -naphthol. MORITZ KOHN AND ALFONS OSTERSETZER. *Monatsh.* 39, 299-306(1918); *J. Chem. Soc.* 114, I, 501-2. —The yellow quinonoid oxidation product of methylenedi- $\beta$ -naphthol was regarded by Abel as having the peroxide structure (I), but the *o*-quinonoid formula (II), is now

proposed. This structure is in accordance with the formation of a *phenylhydrazone*,  $\text{C}_{27}\text{H}_{18}\text{ON}_2$ , orange-red needles, m.  $153-6^\circ$ , only the *o*-quinonoid CO group reacting with the usual reagent for ketonic substances; the phenylhydrazone on reduction with Zn and alc. AcOH yields a *dihydro derivative*,  $\text{C}_{27}\text{H}_{20}\text{ON}_2$ , colorless powder, m.  $133-6^\circ$ ; this deriv. is probably a hydrazo compd., while the parent phenylhydrazone is of the azo structure. With  $\text{MeMgI}$ , the quinonoid compound reacts, forming a *substance*,  $\text{C}_{22}\text{H}_{18}\text{O}_2$ , probably (III), needles, m.  $135-45^\circ$ , and with  $\text{PhMgBr}$  an analogous compound,  $\text{C}_{27}\text{H}_{20}\text{O}_2$ , prisms, m.  $130-70^\circ$ , is obtained.  $\text{Me}_2\text{SO}_4$  converts methylenedi- $\beta$ -naphthol into the *dimethyl ether*,  $\text{C}_{22}\text{H}_{18}\text{O}_2$ , leaflets, m.  $144-7^\circ$ . C. J. WEST.

Attempted synthesis of 3,4,8,9-dibenzopyrene. RICHARD WEITZENBÖCK. *Monatsh.* 39, 307-13(1918); *J. Chem. Soc.* 114, I, 493-4. —By the synthetic method already discovered for pyrene it should be possible to produce pyrene derivs. containing condensed hydrocarbon nuclei. This paper records an unfinished investigation in this direction. 1,1'-Dimethyl-2,2'-dinaphthyl (*a*), prepd. by the action of Cu on 1,2- $\text{C}_{10}\text{H}_7\text{MeI}$ , is accompanied by a *substance*,  $\text{C}_{22}\text{H}_{18}$ , leaflets, m.  $314-6^\circ$ ; *picrate*, brick-red needles, m.  $199-201^\circ$ . When brominated in boiling  $\text{PhNO}_2$  (*A*) is converted into 1,1'-dibromomethyl-2,2'-dinaphthyl,  $\text{C}_{22}\text{H}_{16}\text{Br}_2$ , needles, m.  $200-1^\circ$ , which reacts with aq.-alc. KCN yielding 2,2'-dinaphthylene-1,1'-diacetonitrile, crystals, m.  $246^\circ$ , this on hydrolysis with alc. KOH at  $150^\circ$ , gives 2,2'-dinaphthylene-1,1'-diacetic acid (I). From

this, by the stages represented by formulas (II) and (III) it should be possible to obtain 3,4,8,9-dibenzopyrene (IV). In a preliminary investigation with a view to a new pyrene synthesis, *o*- $\text{IC}_6\text{H}_4\text{CHClCHClCO}_2\text{H}$ , obtained by the action of Cl on a  $\text{CS}_2$  soln. of

$o\text{-IC}_6\text{H}_4\text{CH:CHCO}_2\text{H}$ , was steamed distd. in the presence of excess of  $\text{Na}_2\text{CO}_3$  with the formation *o*-iodostyryl chloride,  $\text{C}_6\text{H}_4\text{ICH:CHCl}$ ,  $b_m$   $151^\circ$ . C. J. WEST.

Synthesis of the isomeric hydrocarbons 1,2,5,6-dibenzanthracene and 3,4,5,6-dibenzophenanthrene. RICHARD WEITZENBÖCK AND ALBERT KLINGLER. *Monatsh.* 39, 315-23(1918); *J. Chem. Soc.* 114, I, 494.—When heated with  $o\text{-NO}_2\text{C}_6\text{H}_4\text{CHO}$  in  $\text{Ac}_2\text{O}$ , K phenylenediacetate undergoes conversion into *o*-nitrobenzylidene-*p*-phenylenedi-acetic acid,  $\text{HO}_2\text{CCH}_2\text{C}_6\text{H}_4(\text{CO}_2\text{H})\text{:CHC}_6\text{H}_4\text{NO}_2$ , needles,  $m.$   $236^\circ$ , which by further treatment can be made to yield *di-o*-nitrobenzylidene-*p*-phenylenedi-acetic acid,  $\text{C}_6\text{H}_4(\text{C}(\text{CO}_2\text{H})\text{:CHC}_6\text{H}_4\text{NO}_2)_2$ , pale yellow prisms,  $m.$   $308^\circ$  (decompn.). This substance on reduction in  $\text{NH}_4\text{OH}$  with  $\text{Fe}(\text{OH})_2$  gives *di-o*-aminobenzylidene-*p*-phenylenedi-acetic acid, yellow needles,  $m.$  near  $276^\circ$ , which by diazotization and subsequent treatment with Cu powder can be made to yield a mixt. of 1,2,5,6-dibenzanthracenedicarboxylic acid and 3,4,5,6-dibenzophenanthracenedicarboxylic acid; these were not sepd., the mixt. being directly converted by heating under reduced pressure into a mixt. of the corresponding hydrocarbons, which were then sepd. by crystn. from  $\text{AcOH}$ . The less sol. 1,2,5,6-dibenzanthracene (I) forms silvery leaflets,  $m.$   $262^\circ$  (picrate,  $\text{C}_{22}\text{H}_{14.2}\text{C}_6\text{H}_5\text{O}_7\text{N}_3$ , orange needles,  $m.$   $214^\circ$ ), gives a red soln. with alk.  $\text{Na}_2\text{S}_2\text{O}_4$  soln. and is oxidized by  $\text{K}_2\text{CrO}_4$  in  $\text{AcOH}$  to 1,2,5,6-dibenzanthraquinone,  $\text{C}_{22}\text{H}_{12}\text{O}_2$ , orange needles,  $m.$   $248\text{--}9^\circ$ , while the more sol. 3,4,5,6-dibenzophenanthracene (II) forms colorless needles,  $m.$   $145\text{--}6^\circ$ .

C. J. WEST.

Nature of cyclic quinoneimide dyes. F. KEHRMANN. *Ann.* 414, 131-88(1918); *J. Chem. Soc.* 114, I, 449-50.—This is a theoretical paper, containing a discussion of the results of investigations of the constitutions of cyclic quinoneimide dyes. The classes discussed are azonium compounds (azines, safranines, indulines), azthionium (thionines), azoxonium (azoxines), carboxonium and carbothionium (pyronines), rosamines, thiopyronines, cyanopyronines, cyanoacridines and acridonium. The discussion starts with the desmotropy of 6-hydroxynaphthaphenazine recorded by K. and Messinger in 1891, and this strikes the keynote of K.'s treatment of the subject. The dyes in general are regarded as desmotropic substances which acquire the *o*- or *p*-quinonoid structure according to the conditions, *e. g.*, rosinduline and induline salts are *o*-quinonoid, but the free bases are *p*-quinonoid. C. J. WEST.

Aminohydrazines. V. *m*-Amino-*p*-tolyl- $\beta$ -benzylhydrazine. HARTWIG FRANZEN AND CORLESTIN MONDLANGE. *Ann.* 414, 189-95(1918); *J. Chem. Soc.* 114, I, 458.—This aminohydrazine has been examd. in order to ascertain whether the yellow color and the capacity to form intensely colored salts exhibited by *o*-aminophenyl- $\beta$ -benzylhydrazine are general characteristics of such compds. Benzaldehyde *m*-nitro-*p*-tolylhydrazine in boiling alc.  $\text{NH}_4\text{OH}$  soln. is treated with  $\text{Na}_2\text{S}_2\text{O}_4$ , whereby sodium *m*-amino-*p*-tolyl- $\beta$ -benzylhydrazinesulfonate and benzaldehyde-*m*-amino-*p*-tolylhydrazone are obtained, which are sepd. by boiling  $\text{H}_2\text{O}$ , in which the former, pale yellow leaflets,  $m.$   $212^\circ$ , is insol. It is decompd. by boiling 0.5 *N*  $\text{H}_2\text{SO}_4$ , yielding  $\text{SO}_2$  and benzaldehyde *m*-amino-*p*-tolylhydrazone, which is then converted into phenylmethylbenziminazole (A) and  $\text{NH}_3$ . Benzaldehyde *m*-amino-*p*-tolylhydrazone, obtained from the hot aq.

filtrate, forms golden yellow leaflets, m.  $167^{\circ}$ , is converted by cold 10% HCl into (A) and  $\text{NH}_3$ , and in boiling alc. is reduced by 3% Na-Hg, yielding *m*-amino-*p*-tolyl- $\beta$ -benzylhydrazine,  $\text{H}_2\text{NC}_6\text{H}_4\text{MeNHNHCH}_2\text{Ph}$ , intensely yellow needles, m.  $87^{\circ}$ , which forms yellow solns. in org. solvents and develops in alc. an intense magenta color on the addition of a little dil. mineral acid.

C. J. WEST.

**Terpenes and ethereal oils.** CXX. O. WALLACH. *Ann.* 414, 195-233 (1918); *J. Chem. Soc.* 114, I, 445-6.—Most of the work has been abstracted previously. (With KURT PELIKAN.) From the accepted formula of pinol hydrate and dihydrocarveol, the expectation is justifiable that the reduction product of the former will be identical with the menthane-2,8-diol obtained from the latter by the addition of  $\text{H}_2\text{O}$ . The expectation, however, is not fulfilled. *i*-Pinol hydrate yields by reduction a glyco-dihydropinol hydrate, m.  $139-41^{\circ}$ , while the *i*-glycol obtained from dihydrocarveol m.  $108-9^{\circ}$ . Also, *d*-pinol hydrate (sobrerol) reduced in MeOH by Paal's method yields a glycol, m.  $158-9^{\circ}$ ,  $[\alpha]_D^{20} -40^{\circ} 26'$  in alc., while the glycol derived from the optically active dihydrocarveol m.  $113-4^{\circ}$ . The behavior of pinol hydrate on reduction, therefore, has been examd. When it is reduced by H and colloidal Pd in the absence of free acid, there occurs, in addition to the normal reduction, a by-reaction, in which the pinol hydrate is dehydrated and the resulting unsatd. monohydric alc. reduced to tetrahydrocarveol. This result not only again shows that unsatd. glycols are not always smoothly reduced to the satd. glycols in the presence of colloidal metal, but is further proof that in pinol hydrate a HO group occurs in position 2. *i*- or *l*-Dihydropinol hydrate is converted into terpinene dihydrobromide by treatment with HBr in glacial AcOH. A similar transformation is not produced by HCl. Moreover, the menthane-2,8-diol obtained from dihydrocarveol does not behave in this way. It is shown that dihydropinol hydrate is not identical with menthane-1,4-diol nor with *menthane-2,4-diol*, obtained by reducing sabinene glycol by Paal's method. The latter diol b,  $135-40^{\circ}$ ; the distillate solidifies completely (m.  $93-4^{\circ}$ ) but seps. as an oil from solvents on account of its great soly. When dehydrated by  $(\text{CO}_2\text{H})_2$  and  $\text{H}_2\text{O}$ , it yields a small quantity of a hydrocarbon, b.  $172-82^{\circ}$ ,  $d_{20} 0.866$ , showing the reactions of terpinene, the main product being an unsatd. *alcohol*,  $\text{C}_{10}\text{H}_{17}\text{OH}$ , b.  $219-21^{\circ}$ ,  $d_{20} 0.9250$ ,  $n_D 1.4790$ , which yields carvenone by oxidation with  $\text{CrO}_3$  and tetrahydrocarveol by reduction by Paal's method. The alc. would therefore appear to be  $\Delta^2$ -menthane-2-ol, but that  $\Delta^{4(8)}$ -menthene-2-ol is also present is indicated by the formation of acetone when the alc. is oxidized by  $\text{KMnO}_4$ . When *i*-dihydropinol hydrate is warmed with  $(\text{CO}_2\text{H})_2$  and  $\text{H}_2\text{O}$ , the main product is a satd. oxide, having an odor of cineole. Dihydrocarveol is formed as a by-product. CXXI. Pulegenic acid and the conversion of carvone into pulegenic acid. *Ibid* 414, 233-43 (1918); *J. Chem. Soc.* 114, I, 428-9.—An improved method of prepg. pulegenic acid is to shake pulegone dibromide with aq. KOH for 1 hr. at the ordinary temp. and then for 3 hrs. at  $100^{\circ}$ . Unchanged pulegone and methylcyclohexanone are removed by steam and pulegenic acid is extd. by  $\text{Et}_2\text{O}$  from the somewhat concd. acidified residual soln. Like other substances containing a semicyclic linking, pulegenic acid and its amide are difficult to reduce to the satd. condition; this, however, can be carried out as follows: HCl is added to Me pulegenate and then removed again with simultaneous hydrolysis. The product is a mixt. of ordinary pulegenic acid and an isomeride. By distn. under ordinary pressure the former is converted into pulegone, while the latter distils at  $256-60^{\circ}$  with slight decompn. It is converted into its amide, m.  $152^{\circ}$ , which is easily reduced by H and colloidal Pd to dihydropulegenamide, m.  $150-1^{\circ}$  (Eykmán gives  $147^{\circ}$ ), from which dihydropulegenic acid (1-methyl-3-isopropylcyclopentane-2-carboxylic acid), b.  $139^{\circ}$   $d_{20} 0.9600$ ,  $n_D 1.4524$ , is readily obtained. An alternative and more convenient method is to heat Me hydrochloropulegenate with  $\text{PhNH}_2$ , to reduce the resulting unsatd. ester by Skita's

pulegone into the 5-ring pulegic acid under the action of alkali have hitherto not been known. W. has therefore examd. the behavior of a number of di-Br derivs. of menthone and of carvomenthone when digested with 2% aq. KOH at the ordinary temp. for 2-3 days, and finds that the course of the reaction is detd. essentially by the position of the Br atoms. The results may be generalized as follows: (1) Phenols are formed from di-Br derivs. which have been obtained by the addition of Br at an ethylene linking adjacent to the CO group and not sepd. from it by a substituent; e. g., 1,2-dibromomenthone and 3,4-dibromocarvomenthone. The formation of the phenol does not always take place smoothly, comparatively stable monobromides sometimes being formed. (2) When the ethylenic linking is adjacent to the CO group, but is sepd. from it by a substituent, the di-Br deriv., e. g., 4,5-dibromomenthone and 1,6-dibromocarvomenthone, readily undergoes fission of the ring with the production of an aliphatic ketonic acid with the same number of C atoms. (3) When the 2 Br atoms are divided by the nucleus and the side-chains, or are both in the side-chains, the course of the reaction may be very varied and a general rule cannot be formulated. (4) Di-Br derivs. in which the Br atoms are attached to nuclear C atoms on either side of the CO group, e. g., 2,4-dibromomenthone and 1,3-dibromocarvomenthone, are converted into pentacyclic hydroxycarboxylic acids (see following abstr.). (With H. E. WOODMAN.) When shaken for 3 days with 2% aq. KOH, 8,9-dibromomenthan-2-one, prepd. by the bromination of optically active dihydrocarvone, is converted, apart from small quantities of carvacrol and carvenone, into a heavy oil, which loses HBr and yields carvacrol when distd. in vacuum, and is reduced to dihydrocarvone by Zn and aq. NaOH and is therefore probably the monobromide.

The cryst. dihydrocarvone dibromide, m. 69-70°, obtained by brominating 1-dihydrocarvone in glacial AcOH containing HBr, is converted by 2% aq. KOH into an unsatd. *hydroxy ketone*,  $\text{C}_{10}\text{H}_{14}\text{O}_2$ ,  $b_{\text{D}} 140^\circ$ ,  $d_{20} 1.0285$ ,  $n_D 1.4917$  (semicarbazone, m. 123-4°), which yields carvacrol by warming with dil.  $\text{H}_2\text{SO}_4$  and is possibly 8-hydroxy- $\Delta^4$ -menthene-2-one or 8-hydroxy- $\Delta^5$ -menthene-2-one. 3,4-Dibromocarvomenthone is converted by 2% KOH into carvacrol and similarly 1,2-dibromomenthone into *m*-cresol. (With E. H. WOODMAN and W. JESSEN.) 1,6-Dibromocarvomenthone is converted by shaking with 2% KOH for 2-3 hrs. at the ordinary temp. and then for 1-2 hours at 100° into  $\epsilon$ -keto- $\beta$ -isopropylheptoic acid, which is identified as the optically active modification by the formation of the semicarbazone, m. 158-9°, and the oxime, m. 60-3° (rising to 87-9° by recrystn.). (With ADOLF HALLSTEIN.) When 1,2-dibromomenthone is shaken for 16-20 hrs. with the quantity of 2% aq. KOH calcd. to remove all the Br, a *monobromide*,  $\text{C}_{10}\text{H}_{11}\text{OBr}$ , m. 42-3°, is obtained, together with some thymol. The monobromide is converted into thymol by heating it alone, when HBr is evolved, or with MeONa. This behavior and the method of prepn. indicate that the monobromide is 2-bromo- $\Delta^4$ -menthen-3-one, or 2-bromo- $\Delta^1$ -menthen-3-one, but the substance does not react readily with Br and yields by oxidation with  $\text{KMnO}_4$  ( $\text{CO}_2\text{H}$ )<sub>2</sub>, volatile fatty acids and a *ketonic acid*,  $\text{C}_{10}\text{H}_{14}\text{O}_3$ , m. 105-6° (*silver salt*,  $\text{C}_{10}\text{H}_{11}\text{O}_3\text{Ag}$ ; *semicarbazone*, m. 225°); the formation of the last acid is not explicable by either of the formulas given above. (With EMMA GROTE.) 4,5-Dibromomenthone is converted by 2% aq. KOH into an aliphatic *ketonic acid*,  $\text{C}_{10}\text{H}_{14}\text{O}_3$ , *silver salt*,  $\text{C}_{10}\text{H}_{11}\text{O}_3\text{Ag}$ ; *semicarbazone*, m. 161-3° (slowly heated) or 164-6° (rapidly heated), which is probably  $\epsilon$ -keto- $\beta$ , $\delta$ -dimethyloctic acid,  $\text{PrCOCH}_2\text{CH}_2\text{CHMeCH}_2\text{CO}_2\text{H}$ . An unsatisfactory attempt to prep.  $\Delta^4(5)$ -menthen-3-one from 4-bromomenthan-3-one is described. CKXIV. Method of transforming hexacyclic ketones into cyclopentanones based on the conversion of dibrominated cyclohexanones into pentacyclic  $\alpha$ -hydroxycar-

boxylic acids. (With MATHILDE GERHARDT and WILHELM JESSEN.) *Ibid* 414 296-366(1918); *J. Chem. Soc.* 114, I, 442-4.—The brominated cyclohexanones which contain the Br atoms in such positions that pentacyclic  $\alpha$ -hydroxycarboxylic acids are produced by the action of alkalis are in general easily obtained by treating the cyclohexanone in glacial AcOH with 4 atoms of Br. Since cyclopentanones are known only in small numbers while cyclohexanones can be obtained in large numbers, not only from natural sources but also from phenols by Sabatier's method and by Knoevenagel's synthesis, it is of importance to find out whether it is possible quite generally to convert cyclohexanones into pentacyclic  $\alpha$ -hydroxycarboxylic acids with the same number of C atoms, from which cyclopentanones can be obtained by oxidation. Up to the present time 9 cyclohexanones have been converted into cyclopentanones by the elimination of a nuclear methylene group, the pentacyclic  $\alpha$ -hydroxycarboxylic acids being intermediate products. The formation of these would be easily explicable if the original dibromocyclohexanone contained a CBr<sub>2</sub> group adjacent to the CO group, because the alkali would then produce an *o*-diketone, from which the pentacyclic acid would be formed by a benzilic acid transformation. This simple explanation is inapplicable for 2 reasons: It is proved that by direct substitution in menthone and carvomenthone the 2 Br atoms are not attached to 1 and the same C atom, but that 1 Br replaces the tertiary H atom adjacent to the CO group and the other enters the CH<sub>3</sub> group on the other side of the CO group. Although compds. having the compn. of *o*-diketones can be isolated they do not exhibit the properties of such substances but behave as unsatd. ketols. Such compds. derived from the dibromomenthone and dibromocarvomenthone are identical and yield the same pentacyclic hydroxycarboxylic acid. W. explains this schematically as follows for dibromomenthone,

and similarly for the dibromocarvomenthone; the same *o*-diketone is formed in both cases, but when isolated isomerizes to the unsatd. ketol,

The bromination of 1,3-dimethylcyclohexan-5-one in cold glacial AcOH produces 2 di-Br compounds, an  $\alpha$ -dibromide, C<sub>8</sub>H<sub>12</sub>OBr<sub>2</sub>, needles, m. 163-4° (decompn.), which is scarcely attacked by alkali, and an isomeric  $\beta$ -dibromide, prisms, m. 60-1°, which is converted by 2% aq. KOH into the ketol, C<sub>8</sub>H<sub>12</sub>O<sub>2</sub>, m. 71-2°. The ketol, which is removed from the acidified liquid by steam, is converted by concd. aq. KOH at 140° into 4-hydroxy-1,3-dimethylcyclopentane-4-carboxylic acid, C<sub>8</sub>H<sub>14</sub>O<sub>3</sub>, m. crystals, m. 92-3°, which yields 1,3-dimethylcyclopentan-4-one, b. 152-4°, d<sub>17</sub> 0.8950, n<sub>D</sub><sup>17</sup> 1.4330 (semicarbasone, m. 165-6°), by warming with PbO<sub>2</sub> and H<sub>2</sub>SO<sub>4</sub>. CXXV. Compounds

of the eucarvone series. (With MAX STANDACHER.) *Ibid* 414, 376-75(1918); *J. Chem. Soc.* 114, I, 444.—Assuming the constitution given to  $\beta$ -dihydroeucarvoxime (*C. A.* 8, 1572) to be correct, the reduction of this substance should yield tetrahydroeucarvylamine. This is found to be so. When reduced by Na and alc., the oxime is converted into a base,  $C_{10}H_{19}NH_2$ , b.  $208.5^\circ$ ,  $d_{20}$  0.8680,  $n_D$  1.4665, which forms a carbamide, m.  $139^\circ$ , phenylcarbamide, m.  $143-6^\circ$ , trimethylammonium iodide, m. about  $200^\circ$ , and an acetyl derivative, m.  $110.5^\circ$ , the last being identical with the substance obtained by acetylating the base prep'd. by the reduction of tetrahydroeucarvoxime. By bromination in glacial AcOH at  $0^\circ$ , tetrahydroeucarvone yields a monobromo derivative,  $C_{10}H_{17}OBr$ , crystals, m.  $32^\circ$ , which is converted by 3% aq. KOH into hydroxyletetrahydroeucarvone,  $HOC_{10}H_{17}O$ , b.  $128.5^\circ$ ,  $d_{20}$  0.9810,  $n_D$  1.4626 (semicarbazone, m.  $193^\circ$ , oxime, m.  $84^\circ$ , which forms a cryst. sodium salt). The HO compound is reduced to a glycol,  $C_{10}H_{18}(OH)_2$ , b.  $112-7^\circ$ , by Na and alc., and yields a chromate,  $(C_{10}H_{17}O)_2CrO_4$ , when treated with  $H_2SO_4$  and  $CrO_3$  dissolved in a little  $H_2O$ , at a temp. not exceeding  $0^\circ$ . When treated with Br (2 mols.) in glacial AcOH without cooling, tetrahydroeucarvone yields dibromotetrahydroeucarvone,  $C_{10}H_{16}OBr_2$ , prisms, m.  $68^\circ$ , which is converted by 4% aq. KOH at  $100^\circ$  into an acid,  $C_{10}H_{16}O_2$ , crystals, m.  $91.5-92.5^\circ$  (silver salt,  $C_{10}H_{15}O_2Ag$ ). The acid is sat'd., odorless, and somewhat easily volatile with steam. Its constitution has not yet been det'd. When treated with MeOH-MeONa, dibromotetrahydroeucarvone yields a substance,  $C_{10}H_{16}O_2$ , b.  $218-9^\circ$ ,  $d_{20}$  0.979,  $n_D$  1.4698, isomeric with the preceding acid, the nature of which has not yet been ascertained.

C. J. WEST.

$\alpha$ -Naphthoic sulfinide. KURT KALCHER. *Ann.* 414, 244-9(1918); *J. Chem. Soc.* 114, I, 433.— $\alpha, \beta$ - $C_{10}H_6(CN)SO_2Cl$ , m.  $143-4^\circ$ , is converted by  $NH_3$  gas in hot, dry  $C_6H_6$  into  $\alpha$ -cyanonaphthalene- $\beta$ -sulfonamide, monoclinic crystals, decomp.  $330-40^\circ$ , which is converted by boiling 0.1 *N* NaOH (1.25 mols) and subsequent acidification into  $\alpha$ -naphthoic sulfinide,  $C_{10}H_6CO.NH.SO_2$ , clusters of small prisms, m.  $244^\circ$ , to-

gether with the Na salt of an acidic by-product. The sulfinide, which is best purified through its sodium salt, long, flattened needles, has a bitter taste and forms a methyl derivative, leaflets, m.  $220-1^\circ$ , which yields  $MeNH_2$  by hydrolysis with 35% HCl at  $150^\circ$ . The nature of the acidic by-product was not established.

C. J. WEST.

Synthesis of elemicin and of isoelemicin. F. MAUTHNER. *Ann.* 414, 250-5 (1918); *J. Chem. Soc.* 114, I, 428.—2,6-Dimethoxyphenyl allyl ether,  $(MeO)_2C_6H_3OCH_2CH:CH_2$ , colorless oil, b.  $140-1^\circ$ , prep'd. from  $CH_2:CHCH_2Br$  and 2,6-( $MeO$ ) $_2C_6H_3OH$  in boiling acetone in the presence of  $K_2CO_3$ , is converted by heating at  $220^\circ$  in a few min. into 2,6-dimethoxy-4-allylphenol,  $HOC_6H_2(OMe)_2CH_2CH:CH_2$ , b.  $168-9^\circ$ , which yields by methylation with  $Me_2SO_4$  and 10% NaOH 3,4,5-trimethoxyallylbenzene, identical with elemicin. The position of the allyl group is proved by oxidizing the substance in acetone to gallic acid tri-Me ether by  $KMnO_4$  and of the double linking by the decompn. of the ozonide by  $H_2O$  whereby homogallaldehyde tri-Me ether is obtained. By heating with alc. KOH, the synthetic elemicin is converted into isoelemicin (3,4,5-trimethoxypropenylbenzene), the ozonide of which yields gallaldehyde tri-Me ether by decompn. with  $H_2O$ .

C. J. WEST.

Crystalline form of 3,7-dimethyl-1,4-diethyluric acid and of its glycol dimethyl ether. Correction. HEINRICH BILTZ AND FRITZ MAX. *Ann.* 414, 255(1918); *J. Chem. Soc.* 114, I, 455.—The description of the cryst. form of 3,7-dimethyl-1,9-diethyluric acid is really that of its glycol di-Me ether. The former crystals in small rhombohedra with blunted angles.

C. J. WEST.

Action of *o*- and *peri*-diamines and of ethylenediamine on  $\gamma$ -lactones. A. BISTRZYCKI AND WALTHER SCHMUTZ. *Ann.* 415, 1-28(1918); *J. Chem. Soc.* 114, I,

452-4. — The behavior of  $o$ - $C_6H_4(NH_2)_2$  and of  $1,8$ - $C_{10}H_6(NH_2)_2$  with lactones derived from certain alcohol-acids has been examd.; 2 mols. of  $H_2O$  are eliminated and benzimidazole derivs. produced. When lactones derived from phenolic acids are employed, the same derivs. are again obtained but the condensation does not proceed beyond the elimination of 1 mol. of  $H_2O$ . Thus phthalide and  $o$ - $C_6H_4(NH_2)_2 \cdot HCl$ , heated at  $180$ – $200^\circ$ , yield the  $HCl$  salt of  $o$ -benzylenebenzimidazole, m.  $212$ – $3^\circ$  (*picrate*, yellow needles, decomp.  $243^\circ$ ) while phthalide and  $1,8$ - $C_{10}H_6(NH_2)_2$  in a similar reaction yield the  $HCl$  salt of benzyleneperimidine (phthaloperine). While phthalophenone does not react with  $o$ - $C_6H_4(NH_2)_2$  nor its  $HCl$  salt nor with  $1,2,4$ - $C_6H_3(NH_2)_3OEt$ , phenolphthalein reacts extremely vigorously with the former at  $230^\circ$ , yielding *di-p-hydroxyphenylbenzylenebenzimidazole*, (I), needles, decomp.  $354$ – $55^\circ$ , which gives a colorless soln. in dil.

aq.  $KOH$  and forms a *picrate*, stout prisms, m.  $203$ – $4^\circ$ , and a *diacetate*, best isolated in the form of the *picrate*  $C_{28}H_{23}O_{11}N_3$ , yellow needles, decomp.  $285$ – $6^\circ$ . When a mixt. of valerolactone and  $o$ - $C_6H_4(NH_2)_2$  is heated, finally at  $270^\circ$ , *1,2*-(*1'*-methyltrimethylene)-benzimidazole (II) is obtained in poor yield as a brown oil; the *picrate*, yellow microscopic prisms, m.  $22$ – $4^\circ$  (darkening).  $o$ - $C_6H_4(NH_2)_2$  and the lactone of *o*-hydroxydiphenylacetic acid react quant. at  $120$ – $30^\circ$  to give *2-o-hydroxybenzohydrylbenzimidazole*,  $NH_2C_6H_4N : CCHPhC_6H_4OH$ , m.  $246$ – $7^\circ$ , which seps. from  $EtOH$  or  $C_6H_6$  in micro-

scopic, colorless leaflets containing 1 mol. of solvent and forms a *picrate*, stout, yellow prisms, m.  $216^\circ$ , with previous darkening; attempts to eliminate a 2nd mol. of water by fusion with  $P_2O_5$  or  $ZnCl_2$  were unsuccessful. The same lactone reacts with  $1,2,4$ - $C_6H_3(NH_2)_3OEt$  to form *4*-(or *3*)-ethoxy-*2-o-hydroxybenzohydrylbenzimidazole*,  $C_{22}H_{19}O_5N_3 \cdot H_2O$ , prisms, m.  $110$ – $20^\circ$ , with loss of the  $H_2O$  of crystn. With  $1,8$ - $C_{10}H_6(NH_2)_2$  at  $70$ – $100^\circ$  it reacts to form *2-o-hydroxybenzohydrylperimidine*, microscopic plates, m.  $295$ – $7^\circ$  (decompn.) and with the *1,2*-deriv. at  $120$ – $40^\circ$  quant. to form *2-o-hydroxybenzohydrylnaphthimidazole*,  $C_{24}H_{18}ON_3$ , microscopic prisms, m.  $294$ – $5^\circ$ , in which it has not not been detd. whether the  $NH$  group is attached to the  $C_{10}H_6$  nucleus in the  $\alpha$ - or  $\beta$ -position. The lactone of *2*-hydroxy-5-methyltriphenylacetic acid does not react with  $C_6H_4(NH_2)_2$  or its  $HCl$  salt. The behavior of  $C_2H_4(NH_2)_2$  with lactones is quite different from that of the aromatic diamines. When 2 mols. of phthalide in abs. alc. is boiled with a 50% aq. soln. of  $C_2H_4(NH_2)_2$  (1 or 2 mols.) an additive compound, *N,N'*-ethylenebis-[*2-hydroxymethylbenzamide*],  $C_2H_4(NHCOC_6H_4CH_2OH)_2$ , needles, m.  $183.5^\circ$ , is obtained on cooling after pouring into  $H_2O$ ; this forms a *diphenylurethan*,  $C_{24}H_{20}O_4N_4$ , needles, decomp.  $190^\circ$  (rapidly heated), when heated with phenylurea at  $160^\circ$ , and is oxidized by  $CrO_3$  in glacial  $AcOH$  to the dicarboxylic acid, which immediately changes to dipthalylethylenediimide by loss of  $H_2O$ . The additive compound loses  $H_2O$  above its m. p., and undergoes a partial change into *N,N'*-ethylenedipthalimide (III), prisms or needles, m.  $227.5$ – $9^\circ$ , which is also obtained in 80–90% yield by

beating phthalide (2 mols.) and  $C_2H_4(NH_2)_2$  at  $300^\circ$  for 3 hrs. It is quite stable to boiling aq. or alc.  $KOH$ . By treatment with boiling  $CrO_3$  and pure  $AcOH$  it can be oxidized successively to *N,N'*-ethylenephthalimidephthalimidine (IV), needles, m.  $190$ – $1^\circ$ , and to *N,N'*-ethylenedipthalimide (dipthalylethylenediimide, Anderlini). The former of these is hydrolyzed by hot, moderately dil. aq.  $KOH$  to *N,N'*-ethylenephthal-

imidine-*o*-carboxybenzamide,  $\text{CO} \cdot \text{C}_6\text{H}_4 \cdot \text{CH}_2 \cdot \text{NCH}_2\text{CH}_2\text{NHCOC}_6\text{H}_4\text{CO}_2\text{H}$ , prisms,

decomp.  $172-3^\circ$  (*silver salt*,  $\text{C}_{18}\text{H}_{16}\text{O}_4\text{N}_2\text{Ag}$ , tufts of needles). When treated with Br (2 mols.) in glacial AcOH, which is then boiled for a few min., ethylenediphthalimidine yields a *tribromide*,  $\text{C}_{18}\text{H}_{16}\text{O}_3\text{N}_2\text{Br}_3$ , unstable, yellowish brown needles, decomp.  $187^\circ$  (rapidly heated), which is immediately decompd. by  $\text{H}_2\text{O}$  with regeneration of the imidine. Cl does not attack the imidine in glacial AcOH or  $\text{CCl}_4$ , but in the former soln. together with  $\text{Et}_2\text{O}$ , I produces a *diiodide*,  $\text{C}_{18}\text{H}_{16}\text{O}_3\text{N}_2\text{I}_2$ , dark brown prisms, m.  $180-1^\circ$ . Ethylenediphthalimidine is converted into diphthalyleneimidine by boiling with  $\text{PCl}_5$  and  $\text{POCl}_3$  and by heating with S at  $250^\circ$  until  $\text{H}_2\text{S}$  ceases to be evolved, yields *1,2,3,4-dibenzoylene-1,4,5,6-tetrahydropyrazine* (V), brownish orange needles, m.  $202-3^\circ$ . This

substance which is more easily obtained by heating a mixt. of phthalide,  $\text{C}_6\text{H}_4(\text{NH}_2)_2$  and S in a sealed tube at  $250^\circ$ , is oxidized to diphthalylethylenediimide by  $\text{CrO}_3$  and AcOH.  $\text{C}_6\text{H}_4(\text{NH}_2)_2$  (anhydrous or in 50% aq. soln.) reacts vigorously with the lactone of *o*- $\text{HOC}_6\text{H}_4\text{CH}_2\text{CO}_2\text{H}$  (2 mols.) and it is preferable to add alc. as a diluent; the product is *N,N'*-ethylenebis-[*o*-hydroxyphenylacetamide],  $\text{C}_6\text{H}_4(\text{NHCOCH}_2\text{C}_6\text{H}_4\text{OH})_2$ , needles, m.  $208^\circ$ , which forms a *diphenylurethan*,  $\text{C}_{22}\text{H}_{18}\text{O}_4\text{N}_4$ , needles, m.  $225^\circ$ . Still more vigorously react 50% aq.  $\text{C}_6\text{H}_4(\text{NH}_2)_2$  and the lactone of *o*- $\text{HOC}_6\text{H}_4\text{CHPhCO}_2\text{H}$ , and alc. must be added to keep the reaction under control. The product is *N-o*-hydroxydiphenylacetylene-diamine,  $\text{HOC}_6\text{H}_4\text{CHPhCONHCH}_2\text{CH}_2\text{NH}_2$ , needles, decomp.  $197^\circ$ , whether 1 or 2 mols. of the lactone is present. C. J. WEST.

**Theory of ring closure.** RICHARD MEYER AND HERMANN LÜDERS. *Ann.* 415, 29-50 (1918); *J. Chem. Soc.* 114, I, 450-2.—Since Thiele and Falk have shown that Anderlini's so-called *o*-phenylenephthalamide prepd. from *o*- $\text{C}_6\text{H}_4(\text{NH}_2)_2$  and  $\text{C}_6\text{H}_4(\text{CO}_2\text{H})_2$  is really 2-carboxyphenylbenziminazole, M. and L. have reinvestigated the action of *o*- $\text{C}_6\text{H}_4(\text{NH}_2)_2$  with succinic acid and find that 2 compds. only are formed, not 3 as stated previously, the substance, m.  $236^\circ$ , supposed to be the 8-ring *o*-phenylenesuccinamide, being identical with benziminazole-2-propionic acid. It yields a *methyl ester*, quadratic leaflets, m.  $144-5^\circ$ ; *ethyl ester*, needles, m.  $135-6^\circ$ , and *amide*, prismatic needles, m.  $254^\circ$  (decompn.). The *silver salt*, small prisms, *copper salt*, blue plates, and *chloroplatinate*, yellow crystals, are described, and also the *chloroaurate of the methyl ester*. By heating at  $230-40^\circ$ , it loses  $\text{H}_2\text{O}$  and yields *1,2-propionylenebenziminazole*,

needles, m.  $170^\circ$ . Since, therefore, the compds. obtained from *o*- $\text{C}_6\text{H}_4(\text{NH}_2)_2$  and  $\text{C}_6\text{H}_4(\text{CO}_2\text{H})_2$  and succinic acid, resp., are 5-ring, not 8-ring compds., the behavior of

the diamine with other dibasic acids requires reinvestigation. Cox (*Diss.*, Strassburg, 1908) has already shown that the product from the diamine and malonic acid is easily split into its generators, does not contain a  $\text{CO}_2\text{H}$  group and is the 7-membered ring *o*-phenylenemalonamide, as stated by Meyer. It is now shown that the product from  $o\text{-C}_6\text{H}_4(\text{NH}_2)_2$  and Et isosuccinate behaves similarly and is, as stated previously, the 7-ring *o*-phenyleneisosuccinamide, although its infusibility and sparing soly. suggests that the mol. is polymerized. The reactivity of the methine H atom in Et isosuccinate has been investigated. No reaction occurs with  $\text{HCHO}$  or  $\text{BzH}$ , and the Na deriv. of the ester does not yield condensation products with  $(\text{CH}_3\text{COCl})_2$  or  $o\text{-C}_6\text{H}_4(\text{COCl})_2$ , but reacts with  $\text{BzCl}$  and with  $\text{PhCH:CHCOCl}$  in dry  $\text{Et}_2\text{O}$  to form *ethyl  $\alpha$ -benzoylisosuccinate*,  $\text{CMeBz}(\text{CO}_2\text{Et})_2$ , small, quadratic plates, m.  $36\text{--}8^\circ$ ,  $b_{11}$   $193\text{--}5^\circ$ , and *ethyl  $\alpha$ -cinnamylisosuccinate*, a pale yellow viscous liquid,  $b_{11}$   $225\text{--}30^\circ$ , resp. Isosuccinic acid and  $\text{BzOH}$  or cinnamic acid are obtained when attempts are made to hydrolyze the esters and the reaction with  $\text{PhNHNH}_2$  results in the formation of Et isosuccinate and  $\text{PhNHNHBz}$ . When heated slowly, *m*-nitrophthalanilic acid apparently m.  $240^\circ$  (Meyer) but when heated rapidly it m.  $202^\circ$  with violent foaming (Tingle and Rolker), resolidifies and m. again  $240^\circ$ . This phenomenon is due to the conversion of the anilic acid into the anil, which m.  $240\text{--}2^\circ$ . The anilic acid crystals in colorless needles, not faintly yellow, as previously stated by Meyer. The fusion of *p*-nitrophthalanilic acid is similar; at  $190\text{--}2^\circ$  fusion occurs with violent foaming, and the product resolidifies, and m. again  $260^\circ$ , the m. p. of the anil. *o*-Nitrophthalanilic acid, yellow leaflets, m.  $146\text{--}8^\circ$  (without decompn.) but at  $190\text{--}200^\circ$  it loses  $\text{H}_2\text{O}$  and yields the anil, needles m.  $200\text{--}1^\circ$ . *m*-Nitrosuccinanilic acid m.  $179^\circ$ , and the anil at  $174^\circ$ . C. J. WEST.

Action of the chlorides of phosphorus on phenolsulfonic acids. II. RICHARD ANSCHUTZ AND EUGEN MOLINEUS. *Ann.* 415, 51–64(1918); *J. Chem. Soc.* 114, I, 423.—*p*-Chlorosulfonyl dichloro-orthophosphate,  $\text{ClO}_2\text{SC}_6\text{H}_4\text{OPOCl}_2$ , is converted by heating with an equimol. quant. of  $\text{PCl}_5$  at  $180^\circ$  into *p*- $\text{ClC}_6\text{H}_4\text{OPOCl}_2$ , and the latter, treated similarly at  $250^\circ$ , is converted quant. into *p*- $\text{C}_6\text{H}_4\text{Cl}_2$ . *p*-Chlorosulfonylphenyl metaphosphate,  $\text{ClO}_2\text{SC}_6\text{H}_4\text{OPO}_3$ , obtained by heating the corresponding dichloride with the calcd. amt. of  $\text{H}_2\text{O}$  (weighed in the form of anhydrous  $(\text{CO}_2\text{H})_2$ ), forms transparent crystals and is converted into *p*-chlorosulfonylphenyl hydrogen phosphate on exposure to moisture in the air. Potassium *p*-acetoxybenzenesulfonate,  $\text{KO}_2\text{SC}_6\text{H}_4\text{OAc}$ , crystals, prep'd. by heating *p*- $\text{HOC}_6\text{H}_4\text{SO}_3\text{K}$  with  $\text{Ac}_2\text{O}$  at  $150^\circ$ , is converted by  $\text{PCl}_5$  on the  $\text{H}_2\text{O}$  bath into *p*-acetoxybenzenesulfonyl chloride, crystals, m.  $78^\circ$ ,  $b_{11}$   $148^\circ$ , which reacts in  $\text{Et}_2\text{O}$  with  $\text{PhNH}_2$ , *p*- $\text{MeC}_6\text{H}_4\text{NH}_2$ , and piperidine (2 mols.) to form the *anilide*, m.  $126\text{--}7^\circ$ , *p*-toluidide, m.  $98\text{--}9^\circ$ , and *piperidide*, m.  $115\text{--}6^\circ$ , resp. These 3 substances are converted by heating with alc. (the 1st requires KOH in addition) into *phenol-p-sulfonanilide*, needles, m.  $137\text{--}8^\circ$ , *p*-toluidide, needles, m.  $151\text{--}2^\circ$ , and *piperidide*, m.  $132\text{--}3^\circ$ , resp. When heated with  $\text{CCl}_4$  and  $\text{PCl}_5$  at  $180\text{--}200^\circ$ ,  $2,6,4\text{-Br}_3(\text{ClO}_2\text{S})\text{C}_6\text{H}_3\text{OPOCl}_2$  is converted into *4-chloro-3,5-dibromobenzenesulfonyl chloride*,  $\text{C}_6\text{H}_2\text{ClBr}_2\text{SO}_2\text{Cl}$ , crystals, m.  $94.5^\circ$ , and this is converted into  $1,2,4,6\text{-C}_6\text{H}_2\text{Cl}_4$  by  $\text{PCl}_5$  at  $200^\circ$ .

C. J. WEST.

Sulfonylides. RICHARD ANSCHUTZ. *Ann.* 415, 64–97(1918); *J. Chem. Soc.* 114, I, 424–5.—(With CLARA ZYMANDL.) *o*-Chlorosulfonylphenyl dichloro-orthophosphate,  $\text{ClO}_2\text{S.C}_6\text{H}_3\text{OPOCl}_2$ , yellow oil, b.  $185^\circ$ , obtained from  $2\text{-HOC}_6\text{H}_3\text{SO}_3\text{Na}$  and  $\text{PCl}_5$  (rather more than 1 mol.), is converted by heating with  $\text{PCl}_5$  at  $150^\circ$  into *o*-chlorophenyl dichloro-orthophosphate, pale yellow oil,  $b_{11}$   $135\text{--}7^\circ$ , which yields *o*- $\text{ClC}_6\text{H}_4\text{OH}$  by boiling with  $\text{H}_2\text{O}$ , and *o*- $\text{C}_6\text{H}_4\text{Cl}_2$  by heating with  $\text{PCl}_5$  at  $250^\circ$ . Sodium acetoxybenzenesulfonate,  $\text{AcOC}_6\text{H}_5\text{SO}_2\text{Na}$ , obtained by heating the  $\text{HOC}_6\text{H}_5\text{SO}_3\text{Na}$  with  $\text{Ac}_2\text{O}$ , is converted by  $\text{PCl}_5$  into *acetoxybenzene-o-sulfonyl chloride*, colorless crystals, m.  $73.2\text{--}3.9^\circ$ , which yields the *sulfonanilide*,  $\text{AcOC}_6\text{H}_5\text{SO}_2\text{NHPh}$ , m.  $106\text{--}7^\circ$ , and *sulfono-p-toluide*,

leaflets, m.  $116-7^{\circ}$ , by treatment with  $\text{PhNH}_2$  and  $p\text{-MeC}_6\text{H}_4\text{NH}_2$ , resp.; these are hydrolyzed, the latter by boiling alc. KOH, yielding *phenol-o-sulfonanilide*,  $\text{HOC}_6\text{H}_4\text{SO}_2\text{NHPh}$ , leaflets, m.  $124-5^{\circ}$ , each of which develops a violet color with alc.  $\text{FeCl}_3$ . Phenylene-*o*-sulfonylide is produced when a soln. of acetoxybenzene-*o*-sulfonyl chloride is treated with ethereal gaseous  $\text{NH}_3$  or with an ethereal solution of  $\text{Et}_3\text{NH}$ ,  $\text{AcCl}$  being eliminated. (With L. HODGENIUS.)—Sodium 4-acetoxytoluene-3-sulfonate, prepd. from *p*-cresolsulfonate and  $\text{Ac}_2\text{O}$ , is converted by  $\text{PCl}_5$  into 4-acetoxytoluene-3-sulfonyl chloride, m.  $55-6^{\circ}$ , b<sub>10</sub>  $165-70^{\circ}$ , which yields tolylene-3,4-sulfonylide by treatment with ethereal  $\text{NH}_3$  or  $\text{Et}_3\text{NH}$ . The following three compds. are prepd. by methods similar to the preceding: sodium 4-acetoxytoluene-3,5-disulfonate, 4-acetoxytoluene-3,5-disulfonyldiethylamide,  $\text{AcOC}_6\text{H}_2\text{Me}(\text{SO}_2\text{NEt}_2)_2$ , crystals, m.  $150^{\circ}$ , and 4-acetoxytoluene-3,5-disulfonyl chloride, crystals, m.  $115^{\circ}$ . Tolylene-3,4-sulfonylide-5,5'-disulfonic acid,  $\text{HO}_3\text{SC}_6\text{H}_2\text{Me}:(\text{OSO}_2)_2:\text{C}_6\text{H}_2\text{MeSO}_3\text{H}\cdot 3\text{H}_2\text{O}$ , is prepd. by treating *p*-cresol-3,5-disulfonic acid with fuming  $\text{H}_2\text{SO}_4$  (60%  $\text{SO}_3$ ), finally at  $100^{\circ}$  with the further addition of the fuming acid and recrystg. the ppt. from dil.  $\text{HNO}_3$ ; it forms a K salt, long needles with 5.5  $\text{H}_2\text{O}$ , a silver salt, needles, and a ferric salt, needles, and when anhydrous reacts with  $\text{PCl}_5$  to form tolylene-3,4-sulfonylide-5,5'-disulfonyl chloride, crystals, decomp. about  $280^{\circ}$ , which is stable to boiling  $\text{H}_2\text{O}$ . 4-*tert*-butylphenol-3-sulfonic acid,  $\text{Me}_3\text{CC}_6\text{H}_4(\text{OH})\text{SO}_3\text{H}$ , is obtained by heating *p*-*tert*-butylphenol with pure  $\text{H}_2\text{SO}_4$  at  $70-80^{\circ}$ . Its sodium salt, anhydrous crystals, yields by acetylation sodium 4-acetoxy-1-*tert*-butylbenzene-3-sulfonate, which is converted by  $\text{PCl}_5$  on the  $\text{H}_2\text{O}$  bath into 4-acetoxy-1-*tert*-butylbenzene-3-sulfonyl chloride, crystals, m.  $103^{\circ}$ . *tert*-Butylphenylene-3,4-sulfonylide,  $(\text{Me}_3\text{CC}_6\text{H}_4:\text{OSO}_2)_2$ , microscopic needles, m.  $301-2^{\circ}$ , is obtained by the action of  $\text{POCl}_3$  on 1,4-*tert*-butylphenol-3-sulfonic acid. The following amyl compds. are prepd. like the corresponding Bu compds.: 1,4-*tert*-amylphenol-3-sulfonic acid, and its sodium salt, sodium-4-acetoxy-1-*tert*-amylbenzene-3-sulfonate, 4-acetoxy-1-*tert*-amylbenzene-3-sulfonyl chloride, b<sub>14</sub>  $142-6^{\circ}$ , and *tert*-amylphenylene-3,4-sulfonylide, crystals, m.  $228-9^{\circ}$ . The substance obtained by Schiff (Ann. 178, 187(1875)) by treating sulfotannic acid or its Ac deriv. with  $\text{Ac}_2\text{O}$  is 5,6-diacetoxy-*o*-phenylenesulfonylide. (With MARIA MAXIM.) Sodium 2-acetoxynaphthalene-1-sulfonate, faintly red needles, prepd. by acetylating the naphtholsulfonate, is converted by  $\text{PCl}_5$  in the presence of  $\text{CHCl}_3$  into 2-acetoxynaphthalene-1-sulfonyl chloride, crystals, m.  $115^{\circ}$ , which cannot be converted into a sulfonylide by means of  $\text{C}_6\text{H}_5\text{N}$ ; neither can 2-naphthol-1-sulfonyl chloride, needles, m.  $124^{\circ}$ , obtained by hydrolyzing the Ac deriv. with warm dil. NaOH. The following derivs. of  $1,2\text{-C}_{10}\text{H}_6(\text{OH})\text{SO}_3\text{H}$  can be obtained by methods similar to those already described: potassium 1-acetoxynaphthalene-2-sulfonate, prisms, 1-acetoxynaphthalene-2-sulfonyl chloride, cryst. powder, m.  $87.5^{\circ}$ , 1-acetoxynaphthalene-2-sulfonamide, stout yellow needles, without a sharp m. p., and the corresponding sulfonanilide,  $\text{AcOC}_{10}\text{H}_6\text{SO}_2\text{NHPh}$ , crystals, m.  $157.5^{\circ}$ , and sulfono-*p*-toluidide, m.  $135.5^{\circ}$ . 2,1-Naphthalenesulfonylide, cryst. powder, decomps. above  $300^{\circ}$ , is obtained (1) by adding  $\text{POCl}_3$  to a mixt. of  $1,2\text{-C}_{10}\text{H}_6(\text{OH})\text{SO}_3\text{K}$ ,  $\text{C}_6\text{H}_5\text{N}$  and  $\text{CHCl}_3$  with cooling, (2) by shaking  $1,2\text{-C}_{10}\text{H}_6(\text{OAc})\text{SO}_2\text{Cl}$  with  $\text{C}_6\text{H}_5\text{N}$  at ordinary temp. 2,1- $\text{C}_{10}\text{H}_6(\text{OH})\text{SO}_3\text{Na}$  yields 2-naphthol-1,3,6,7-tetrasulfonic acid by heating with 4 parts of fuming  $\text{H}_2\text{SO}_4$  (40% of  $\text{SO}_3$ ) at  $120-30^{\circ}$  for 8 hrs., but when heated with 5 parts for 2 days is converted into a substance, crystals, which appears to be 3,2-naphthylenesulfonylide-1,6,7,1',6',7'-hexasulfonic acid (sodium salt,  $\text{C}_{10}\text{H}_2\text{O}_{12}\text{S}_6\text{Na}$ , prismatic needles). Acetylisethionyl chloride,  $\text{AcOCH}_2\text{CH}_2\text{SO}_2\text{Cl}$ , b<sub>14</sub>  $130-2^{\circ}$ , obtained together with  $\text{ClCH}_2\text{CH}_2\text{SO}_2\text{Cl}$ , by heating  $\text{AcOCH}_2\text{CH}_2\text{SO}_3\text{K}$  with  $\text{PCl}_5$  on the  $\text{H}_2\text{O}$  bath, cannot be converted into the sulfonylide by means of  $\text{NH}_3$  or  $\text{Et}_3\text{NH}$ ; the sulfonylide also cannot be prepd. from the acid and  $\text{P}_2\text{O}_5$  or  $\text{POCl}_3$ . C. J. Wgstr.

Effects of ring closure on spectrochemical properties. I. Saturated iso- and heterocyclic compounds, unsaturated isocyclic substances and the question of the

constitution of benzene. K. VON AUWERS. *Ann.* 415, 98-168(1918); *J. Chem. Soc.* 114, II, 343.—A. surveys a large field of material and arrives at the following generalizations: Compds. the mols. of which contain 1 or more rings (isocyclic or heterocyclic) without linkings of any kind are optically normal; only when the ring is under tension do the mol. refraction and dispersion exhibit exaltation or depression. The spectrochem. character is unchanged when a satd. side-chain closes to form a ring; e. g., the pairs *o*-MeC<sub>6</sub>H<sub>4</sub>OMe and coumaran and *o*-MeC<sub>6</sub>H<sub>4</sub>OEt and chroman are optically identical and the same holds for a large number of other coumarans and phenolic ethers. The closure of an unsatd. side-chain to a ring causes a weakening of the optical properties, which is the more pronounced the more unsatd. the chain; e. g., styrene deriv. and indene deriv., acyclic dienes and cyclic dienes and acyclic trienes and cyclic trienes. Alkyl groups and other substituents produce an effect opposed to that of ring closure in unsatd. compds. Exceptions occur to all of these generalizations. Contrary to earlier views, double linkings in open and in closed chains are not optically equiv., the spectrochem. effect of the cyclic double linkings being quite generally slighter than that of ethylenic linkings. The 2 physico-chem. methods of investigation, spectrochemistry and thermochemistry, both decide against the view that C<sub>6</sub>H<sub>6</sub> and its hydrogenated derivs. are different in their innermost structure and all the physical and chem. facts ally themselves best to a C<sub>6</sub>H<sub>6</sub> formula containing 3 double linkings. The densities and refractive indices of a number of compds. have been redetd. and new detns. have been made in the case of a large number of coumarans, chromans, phenolic ethers, ketones and indene derivs. The following new substances are described: *as-m-xylyl ethyl ether*, b. 202-3°, d<sub>4</sub><sup>13.96</sup> 0.9487, n<sub>D</sub> 1.50297, n<sub>D</sub> 1.50692, n<sub>B</sub> 1.51874, n<sub>γ</sub> 1.52872 at 13.95°. *5-Bromo-*o*-tolyl ethyl ether*, b. 238-40°, d<sub>4</sub><sup>11.36</sup> 1.3592, n<sub>D</sub> 1.54387, n<sub>γ</sub> 1.54858, n<sub>B</sub> 1.56186, n<sub>γ</sub> 1.57332. *6-Ethoxy-*m*-toluic acid*, needles, m. 200-1°. *Ethyl 6-ethoxy-*m*-toluate*, b. 274-5°, d<sub>4</sub><sup>16.1</sup> 1.0618, n<sub>D</sub> 1.51443, n<sub>D</sub> 1.51908, n<sub>B</sub> 1.53259, n<sub>γ</sub> 1.54428 at 15.1°. *1-Methyl-ac-tetrahydro- $\alpha$ -naphthol*, leaflets, m. 88-9°.

Spectrochemistry and determination of the constitution of tautomeric compounds. K. VON AUWERS. *Ann.* 415, 169-232(1918); *J. Chem. Soc.* 114, II, 381-2.—Brühl showed more than 30 yrs. ago that mol. refraction and dispersion can be utilized to differentiate between enolic and keto-modifications, but the detn. in recent times of the compn. of the keto-enol mixt. by chem. means had frequently led to results which are quite opposed to Brühl's views. A. has undertaken a series of researches, of which this is the first, to ascertain how far spectrochemistry in its present state can be applied to investigations of desmotropic compds. With the difference in structure represented by the scheme —COCHR, —C(OH)CR, correspond const. differences in the mol. refraction and dispersion of such magnitude that a trustworthy decision between the 2 structures can be made only when homogenous substances are in question; also the % compn. of mixts. of simple enols and ketones, e. g., a simple unsatd. alc. and the isomeric aldehyde or ketone, can be ascertained with satisfactory accuracy by the refractometric method, especially if the sp. refraction and dispersion are employed instead of the mol. magnitude. Errors arise, however, and false conclusions may be drawn when certain groups are present in the mol. E. g., in  $\beta$ -diketones,  $\beta$ -ketonic acids, etc., occur the systems —COCHRCOR'— and OHC:CRCR':O. The former is spectrochem. normal, but the latter, containing a conjugate system of linkings, exhibits an abnormal increase of the refraction and still more so of the dispersion. Almost the only possible way of overcoming this difficulty is the calcn. of the magnitude of the exaltation by means of known regularities. Eisenlohr and Auwers have shown that the magnitudes of the sp. exaltations of the refraction and dispersion remain practically const. in compds. containing the same conjugate system, so that "normal values" of

the sp. exaltations can be recorded. Unfortunately, this regularity is not equally sharp for all classes of substances, possibly on account of exptl. error or lack of purity of the compds. examd. It is necessary, therefore, to det. more accurately than hitherto the normal values of the sp. exaltations for the conjugate systems  $-\text{CH}:\text{CH}:\text{CR}:\text{O}$ , and  $-\text{CH}:\text{CH}(\text{COR}):\text{O}$ , and to ascertain the influence of disturbing substituents on these values. By means of the numbers so obtained, the theoretical values of the mol. refraction and dispersion of the enols can be calcd. and thus the foundations laid for a more trustworthy detn. of the equil. proportions of enolic and keto-modifications by means of the optical constns. A. then discusses the values obtained for series of hydroxymethylene compds. and their ethers and esters and draws the conclusion that a trustworthy calcn. of the real mol. refraction and dispersion of enols is possible at the present time in only a few cases in which specially favorable comparison material is available. The following substances have been examd.: The % are calcd. from the spectrochem. data and the figures in parentheses are the % found by Meyer's Br method. Et diacetoacetate, % of keto-enol, 100 (90-100); acetylacetone, enol 69% (76); methylacetylacetone, keto-enol 38 and 31% in 2 different preps. (31); Et acetylmalonate, enol 70% (64); Me benzoylacetate, enol 25% (16.7); Et benzoylacetate, enol 29% (29); Et  $\alpha$ -benzoylbutyrate, enol at most a few units %; methylbenzoylacetone, enol 22% (6). The spectrochem. constns. (density and refractive indices for the  $\alpha$ , D,  $\beta$  and  $\gamma$  lines) have been detd. of the following hydroxymethylene compds. and their Et ethers and esters:  $\gamma$ -keto- $\beta$ -methyl- $\Delta^2$ -penten- $\alpha$ -ol; hydroxymethylene-pinacoln (*ethyl ether*,  $b_{18}$  103-4°; acetate, rhombohedral plates, m. 44-5°,  $b_{18}$  118-8.5°); 2-hydroxymethylenementhone; 2-hydroxymethylenecyclohexanone (*ethyl ether*,  $b_{18}$  128.2-8.4°; acetate,  $b_{14}$  142-3°); Et  $\beta$ -acetoxyacrylate; Et  $\beta$ -hydroxy- $\alpha$ -methylacrylate; Et hydroxymethyleneacetoacetate; Et hydroxymethylenemalonate. The constns. are also given for the following diketones and ketonic esters: acetylacetone (and *O*-methyl (and ethyl ethers); methylacetylacetone; dimethylacetylacetone; ethylacetylacetone; methylbenzoylacetone (and the *O*-methyl ether),  $\beta$ -methoxy- $\beta$ -amylacrylic acid and its Me ether; Et  $\beta$ -ethoxy- $\beta$ -amylacrylate; Et *O*-acetylacetoacetate; Et diacetoacetate; Me benzoylacetate and the Et ester; Et ethylbenzoylacetate.

C. J. WEST.

Colored acid additive products of unsaturated ketones. FRITZ STRAUS AND HUGO BLANKENHORN. *Ann.* 415, 232-56(1918); *J. Chem. Soc.* 114, I, 501.—Mylo has shown that the acetals of aldehydes react with  $\text{PCl}_5$ ,  $\text{SOCl}_2$ , etc., an alkyloxy group being replaced by Cl. It is now shown that acetals of certain unsatd. ketones in  $\text{C}_6\text{H}_6$  soln. react with HCl or, better, with  $\text{PCl}_5$  (1 mol.) in the same way; the products are isolated in the form of yellow- or orange-red complex compds. with  $\text{PCl}_5$  or  $\text{HgCl}_2$ . Thus the acetal of cinnamylidenemethyl phenyl ketone in  $\text{C}_6\text{H}_6$  soln. is treated with  $\text{PCl}_5$  dissolved in  $\text{C}_6\text{H}_6$ , and to the cooled, clear, faintly colored soln. is added, drop by drop, with complete exclusion of  $\text{H}_2\text{O}$ , a soln. of  $\text{HgCl}_2$  in dry  $\text{Et}_2\text{O}$ , whereby the additive compound,  $\text{CHPh}:\text{CHCH}:\text{CHCPhClOMe}.\text{HgCl}_2$ , m. about 110° (decompn.), is pptd. as a red oil, which rapidly solidifies and becomes cryst. In a similar way the acetal of phenyl styryl ketone,  $\text{CHPh}:\text{CHCPh}(\text{OMe})_2$ , needles, m. 46-6.5°, yields the substance,  $\text{CHPh}:\text{CHCPhClOMe}.\text{HgCl}_2$ , yellow crystals, m. about 100° (decompn.); the acetal of *p,p'*-dimethoxybenzophenone, needles, m. 107-8°, yields the substance,  $\text{MeOCCl}(\text{C}_6\text{H}_4\text{OMe})_2.\text{HgCl}_2$ , yellow apparently amorphous powder, and the acetal of benzophenone yields the substance  $2\text{CPh}_2\text{ClOMe}.\text{HgCl}_2$ , almost colorless needles. The substances are converted into the original ketones by hydroxylic solvents, into the original acetals by alc.  $\text{MeONa}$ , and evolve  $\text{MeCl}$  when heated. The bearing of the preceding substances on the constitution of the colored acid additive compds. of the ketones is discussed. The following substances are described: *p*-Chlorophenyl  $\alpha$ -methoxystyryl

ketone,  $\text{MeOC}_6\text{H}_4\text{CH:CHCOC}_6\text{H}_4\text{Cl}$ , yellow needles, m.  $121-2^\circ$ , prepd. from anisaldehyde and  $p\text{-ClC}_6\text{H}_4\text{COMe}$  in aq. alc. containing about 0.5% NaOH. *p*-Anisyl *p*-chlorostyryl ketone, pale yellow crystals, m.  $130-1^\circ$ . *p*-Anisyl *p*-chlorocinnamylidene-methyl ketone, yellow needles, m.  $140^\circ$ . *p*-Chlorophenyl *p*-methoxycinnamylidene-methyl ketone, golden yellow needles, m.  $156^\circ$ ; and *p*-chlorodistyryl ketone, pale yellow needles, m.  $134^\circ$ .

C. J. WEST.

**Derivatives of fulvene. V. Condensation of indene with ketones.** JOHANNES THIELE AND KARL MERCK. *Ann.* 415, 257-73 (1918); *J. Chem. Soc.* 114, I, 484-6. —The reactivity of the  $\text{CH}_2<$  group in cyclopentadiene, indene, and fluorene decreases as the ethylenic linkings of the 5-ring become double linkings in a  $\text{C}_6\text{H}_4$  nucleus. It has already been shown that cyclopentadiene condenses extraordinarily easily with ketones, while fluorene does not condense at all under the influence of alk. condensing agents. The behavior of indene has now been examd. It condenses easily with acetone in the presence of  $\text{MeOH-KOH}$ , yielding, after boiling for 2 hrs., dimethylbenzofulvene (*picrate*, yellow needles, m.  $115-6^\circ$ , sintering at  $102^\circ$ ) but at the ordinary temp., after a week, a mixt. of this and  $\omega, \omega$ -dimethyl-3- $\alpha$ -hydroxyisopropylbenzofulvene (I), m.  $97-8^\circ$ . Dimethylbenzofulvene is not reduced by Al-Hg and moist  $\text{Et}_3\text{O}$ , but is smoothly converted into 3-isopropylindene (II), faintly yellow oil, b. about  $230^\circ$  (de-

compu.), b.  $113^\circ$ , by Na and boiling abs. alc. Indene condenses less readily with aromatic ketones than with acetone. By prolonged boiling with  $\text{BzMe}$  and alc.  $\text{NaOEt}$ , it yields  $\omega$ -phenyl- $\omega$ -methylbenzofulvene, yellow crystals, m.  $68-9^\circ$ , b.  $178-9^\circ$ , and by similar treatment it condenses with  $\text{Ph}_2\text{CO}$  to give  $\omega, \omega$ -diphenylbenzofulvene. These 2 substances are reduced by Al-Hg and moist  $\text{Et}_3\text{O}$  to 3- $\alpha$ -phenylethylidene (III), yel-

low needles, m.  $105.5^\circ$ , and the corresponding methoxybenzylidene compound, yellow crystals, m.  $81^\circ$ , resp. According to Thiele and Büchner's theory of the oscillating linking, the latter of these two compds. ought to be formed by the condensation of 3-*p*-methoxybenzylidene but the product proves to be 3-*p*-methoxybenzyl- $\omega, \omega$ -dimethylbenzofulvene (IV), faintly colored, felted needles, m.  $83^\circ$ . This, like other aliphatic fulvenes, is not reduced by Al-Hg but is converted by Na and boiling abs. alc. into *p*-methoxybenzylisopropylindene, pale yellow oil, b.  $200^\circ$ , which is also obtained by reducing 1-methoxybenzylidene-3-isopropylindene with Al-Hg and moist  $\text{Et}_3\text{O}$ . The condensation of  $\text{BzH}$  with 3-*p*-methoxybenzylidene and of anisaldehyde with 3-benzylidene has therefore been re-examd. and it is now found that the 2 reactions do not give rise to the same substances under suitable conditions. When the condensations are effected by the prolonged action of  $\text{MeOH-KOH}$  at the ordinary temp., the same product, 3-benzyl-1-*p*-methoxybenzylideneindene, is obtained in both cases, but when the 1st pair of substances is boiled with  $\text{MeOH-KOH}$ , for only 2 or 3 min., 3-*p*-methoxybenzyl-1-benzylideneindene, (V) yellow crystals, m.  $89-90^\circ$ , is obtained which readily changes to 3-benzyl-1-*p*-methoxybenzylideneindene by the further action of boiling  $\text{MeOH-KOH}$ . This compd. is not changed by prolonged boiling with  $\text{MeOH-KOH}$  and the same is the case with 3-*p*-methoxybenzyl- $\omega, \omega$ -dimethylbenzofulvene and with 1-*p*-methoxybenzylidene-3-isopropylindene. 3- $\alpha$ -Phenylethylindene (indenyl-methylphenylmethane) condenses with anisaldehyde in the presence of  $\text{MeOH-KOH}$  at the ordinary temp. to form a benzofulvene, yellow needles, m.  $121^\circ$ , but whether this

crystals, m.  $32^{\circ}$ . This with BzH yields 3-*p*-isopropylbenzyl-1-benzylideneindene, yellow needles, m.  $105-7^{\circ}$ . 3-Benzylindene and *p*-iso-PrC<sub>6</sub>H<sub>4</sub>CHO yield 3-benzyl-1-*p*-isopropylbenzylideneindene, yellow needles, m.  $93-4^{\circ}$ , which is converted into a mixt. of the 2 isomers, m.  $71-3^{\circ}$ , by prolonged boiling with MeOH-KOH (10 hrs.). 3-*p*-Chlorobenzylidene and BzH yield 3-*p*-chlorobenzyl-1-benzylideneindene, yellow needles, m.  $98-9^{\circ}$ , and 3-benzylindene and *p*-ClC<sub>6</sub>H<sub>4</sub>CHO yield 3-benzyl-1-*p*-chlorobenzylideneindene, yellow needles, m.  $88-9^{\circ}$ . The last compd. is converted, by boiling for 8 hrs. with MeOH-KOH, partly into a mixt., m.  $79-81^{\circ}$ , of the 2 isomers, and partly into 3-benzyl-1-*p*-chlorobenzylidene, needles, m.  $183-4^{\circ}$ , which is also produced by reducing the benzofulvene with Al-Hg and moist Et<sub>2</sub>O. 3-Methylbenzylidene and *p*-Cl-C<sub>6</sub>H<sub>4</sub>CHO yield 3-*p*-methylbenzyl-1-*p*-chlorobenzylideneindene, large yellow crystals, m.  $95-6^{\circ}$ , together with a small quantity of a substance, needles, m.  $181-3^{\circ}$ , which is probably 1-*p*-chlorobenzyl-3-*p*-methylbenzylidene. 3-*p*-Chlorobenzylidene and *p*-MeC<sub>6</sub>H<sub>4</sub>CHO yield a mixt. of a colorless substance, m.  $182-4^{\circ}$  (1-*p*-chlorobenzyl-3-*p*-methylbenzylidene) and a small quantity of a yellow substance, m.  $91-2^{\circ}$ , which appears to be 3-*p*-methylbenzyl-1-*p*-chlorobenzylideneindene, in a not quite pure state.

C. J. WEST.

**Isomerism of benzofulvenes and indenenes.** H. M. WÜRST. *Ann.* 415, 291-337 (1918); *J. Chem. Soc.* 114, I, 488-492.—With regard to the 8 pairs of isomerides described by Thiele and Merck and by Bernthsen (preceding abstrs.), no generalization in respect to the stability of 1 of the 2 isomers can be drawn, partly because no conclusions can be drawn from the nature of the groups introduced and partly because the transformation from 1 isomer into the other indubitably occurs only in 2 cases and fails entirely only in 2 other cases. A new series of benzofulvenes has, therefore, been examd. The simplest case of isomerism is represented by a 3-substituted benzofulvene (I) and the isomeric  $\omega$ -substituted 3-methylbenzofulvene (II). 3-Methylbenzo-

fulvene (II, R = H), an unstable, faintly yellow, intensely odorous oil,  $b_{11}$   $102-4^{\circ}$  (picrate, yellow needles, m.  $125.5-6.5^{\circ}$ ), is readily obtained by boiling a mixt. of 3-methylindene, (HCHO)<sub>3</sub>, abs. alc., and 28% MeOH-KOH for 12 min., but in no other case could a 3-substituted benzofulvene of type (I) be obtained, the product being always the  $\omega$ -substituted 3-methylbenzofulvene of type (II) owing to the isomerizing action of the alkali used as the condensing agent. Thus 3-benzylindene and (HCHO)<sub>3</sub> yield 1-benzylidene-3-methylindene (picrate, pale red needles, m.  $90-1^{\circ}$ ), 3-*p*-methoxybenzylidene and HCHO yield a mixt. of 1-*p*-anisylidene-3-methylindene and 1-*p*-anisylidene-3-ethylindene, C<sub>10</sub>H<sub>8</sub>O, yellow needles, m.  $100.5-1.5^{\circ}$  (neither of these is changed by boiling for 8 hrs. with MeOH-KOH), 3-methylindene and furfuraldehyde yield, after condensation with MeOH-KOH for 42 hrs. at the ordinary temp., 1-furfurylidene-3-methylindene, deep yellow needles, m.  $77-7.5^{\circ}$  (this compd., which forms a picrate, dark red needles, m.  $97-8^{\circ}$ , is also obtained by boiling 3-furylmethylindene, (HCHO)<sub>3</sub>, abs. alc. and MeOH-KOH for a few sec. and cooling rapidly) and 3-methylindene and Ph<sub>2</sub>CO yield diphenyl-3-methylbenzofulvene, yellow crystals, m.  $120-1^{\circ}$  (picrate, pale red needles, m.  $149-51^{\circ}$ ), the last condensation being effected by boiling with alc. EtOK for 17 hrs. The last mentioned benzofulvene is also obtained by boiling a mixt. of 3-benzhydrylidene, (HCHO)<sub>3</sub>, abs. alc. and MeOH-KOH for 1 hr. The preceding 4

benzofluvenes of type (II) are all intensely yellow and are reducible by Al-Hg and moist  $\text{Et}_2\text{O}$ . The reduction of  $\omega, \omega$ -diphenyl-3-methylbenzofluvene proceeds very slowly and incompletely, the product being 3-benzohydril-1-methylindene, needles, m. 162.5-3.5°. The groups Ph,  $p\text{-MeOC}_6\text{H}_4$ , benzohydril, and furyl in all possible pairs have been systematically introduced into the  $\omega$ - and the 3-positions in benzofluvene. The case of the pair Ph and  $\alpha\text{-MeOC}_6\text{H}_4$  has been investigated by Thiele and Merck; both isomerides are known, 3- $p$ -benzyl-1- $p$ -anisylideneindene being the more stable. Other pairs of isomers which exhibit transformation are the following: 3-Benzohydrilindene and BzH are condensed by MeOH-KOH, after 1 day at the ordinary temp., or after 30 sec. in the boiling soln., yielding 3-benzohydril-1-benzylideneindene, pale yellow needles, m. 131.5-2.5°. If the boiling is prolonged to 5 min., a difficultly separable mixt. of this and its isomer  $\omega, \omega$ -diphenyl-3-benzofluvene, deep yellow, quadratic leaflets, m. 130-0.5°, is obtained. The transformation is easily and completely effected by boiling a mixt. of 3-benzohydrilindene, BzH,  $\text{C}_6\text{H}_5\text{N}$  and MeOH-KOH for 1 min. This method of prepn. is much to be preferred to that in which 3-benzylindene and  $\text{Ph}_3\text{CO}$  are condensed by MeOH-KOH, since in the latter considerable quantities of  $\text{Ph}_3\text{CHOH}$  are formed. Thiele and Merck prepd. 3-benzohydril-1- $p$ -anisylideneindene at the ordinary temp. It is also obtained at the b. p. after 30 sec., but after boiling with alkali for 1 hr. in alc. or  $\text{C}_6\text{H}_5\text{N}$  soln. is transformed into  $\omega, \omega$ -diphenyl-3- $p$ -methoxybenzylbenzofluvene, yellow needles, m. 127-8°. The prepn. of the two following pairs of isomers, containing furyl and Ph or  $p\text{-MeOC}_6\text{H}_4$  groups, at first presented great difficulty, on account of the extreme ease with which the unstable isomer is converted into the stable one. 1-Furfurylideneindene ( $\omega$ -furylbenzofluvene) (I), yellow needles, m. 86-6.5° (picrate, red needles, m. 103-5°), prepd. from indene and furfuraldehyde in boiling MeOH-KOH (5 min.), is reduced by Al-Hg and moist  $\text{Et}_2\text{O}$  to furylmethylindene, almost colorless liquid with a pleasant, aromatic odor, b.p. 166-8°. From the last compd. and BzH 3-furylmethyl-1-benzylideneindene, yellow needles, m. 93-4.5° (clear at 98°), may be obtained merely by shaking with hot MeOH-KOH and immediately pouring the mixt. into  $\text{H}_2\text{O}$ . If the mixt. is boiled even for only 30 sec., the substance is transformed into 1-furfurylidene-3-benzylideneindene (II), faintly yel.

low needles, m. 160.5-1°, which by boiling with MeOH-KOH for 4 hrs. is converted into 1-furfurylidene-3-benzylidene, yellow needles, m. 126-7°; the last substance is obtained directly by the condensation of 3-benzylindene and furfuraldehyde. Using  $p\text{-MeOC}_6\text{H}_4\text{CHO}$  in place of BzH, the following substances are obtained by methods similar to the preceding: 1-Anisylidene-3-furylmethylindene, yellow leaflets, m. 88-9°, 1-anisylidene-3-furfurylideneindene, yellow needles, m. 150-0.5°, and 3- $p$ -methoxybenzyl-1-furfurylideneindene, golden yellow leaflets, m. 127-8°. The condensation of 3-benzohydrilindene and furfuraldehyde by MeOH-KOH, whether boiled for 3 sec. or for 1 hr., yields 3-benzohydril-1-furfurylideneindene, yellow needles, m. 170-0.5°, which is not changed by alkali or even in the presence of  $\text{C}_6\text{H}_5\text{N}$ . The isomer was not prepd. An examn. of all the preceding pairs of isomers shows that in every transformation the double linking shifts so that the partial valencies are balanced as much as possible and consequently the more satd. system is formed. In the 4 cases in which the substituents are a Me group and an aromatic group, the more satd. system is formed so easily that the more unsatd. isomer is unknown. When the substituents are 2 aromatic groups, a partial balance of the valencies occurs in both isomers and the transformation is rendered more difficult and leads to the formation of the isomer in which the exo-

cyclic double linking is conjugated with the more strongly unsatd. substituent. This isomer is therefore the more intensely colored of the pair. *1-Furfurylidene-3-furylhydroxymethylindene* (III), yellow needles, m. 114.5–5°, obtained by condensing indene

and furfuraldehyde by means of cold MeOH-KOH for 6 hrs., is reduced by Al-Hg and moist Et<sub>2</sub>O to *1,3-difurfurylideneindane*, faintly yellow needles, m. 132.5–3.5°, which is also obtained by boiling for 1 min. with alc. KOH. *3-furylmethyl-1-furfurylideneindene*, yellowish brown needles, m. 103–4°, prepd. from 3-furylmethylindene and furfuraldehyde. 3-Arylated benzofulvenes containing 2 aliphatic groups in the ω-positions are quite generally incapable of transformation. ω-Methyl-ω-ethylbenzofulvene, prepd. by boiling indene and MeEtCO with alc. KOH for 5 hrs., is a faintly yellow oil, b<sub>15</sub> 151–2° (*picrate*, orange needles, m. 87.5–88°) which is reduced by Na and abs. alc. to *3-isobutylindene*, oil, b<sub>15</sub> 116–8°. The last substance and Ph<sub>2</sub>CO condense when boiled for 23 hrs. with C<sub>6</sub>H<sub>5</sub>N and alc. KOH to form ω,ω-diphenyl-3-isobutylbenzofulvene, yellow needles or stout prisms, m. 91–2°. 3-Benzohydryl-ω-methyl-ω-ethylbenzofulvene, prepd. from 3-benzohydrylindene and MeEtCO by boiling 15 min. with alc. KOH, is a faintly yellow cryst. powder, m. 149–51°. 3-Isopropylindene and Ph<sub>2</sub>CO yield ω,ω-diphenyl-3-isopropylbenzofulvene, yellow cryst. powder, m. 127–8°. 3-Benzohydrylindene and Me<sub>2</sub>CO yield 3-benzohydryl-ω,ω-dimethylbenzofulvene, yellow cryst. powder, m. 174–5°. The reduction of 3-benzohydryl-1-benzylideneindene and of ω,ω-diphenyl-3-benzylbenzofulvene by Al-Hg and moist Et<sub>2</sub>O leads to the same product, namely, a mixt. of a substance, C<sub>21</sub>H<sub>24</sub>, hard crystals, m. 130–1°, and an isomeric substance, slender needles, m. 137–8°, which are the two benzylbenzohydrylindenes; also the reduction of ω,ω-diphenyl-3-isobutylbenzofulvene yields a mixt. of 2 isomers, *benzohydrylisobutylindene I*, needles, m. 121–3°, and *benzohydrylisobutylindene II*, slender needles, m. 94–5.5°. The latter is obtained from the former by boiling with alc. KOH for 30 min., and also from 3-benzohydryl-ω-methyl-ω-ethylbenzofulvene by reduction with Na and alc. The reduction of benzofulvenes in Et<sub>2</sub>O soln. with Pt black and H leads to the formation of indanes. Thus 3-benzohydryl-ω,ω-dimethylbenzofulvene yields 3-benzohydryl-1-isopropylindane, slender needles, m. 126.5–7.5°, and ω,ω-diphenyl-3-isobutylbenzofulvene yields 1-benzohydryl-3-isobutylindane, m. 104–5°. C. J. WEST.

Energetic oxidation of cholesterol by nitric acid. ADOLF WINDAUS. *Z. physiol. Chem.* 102, 160–5 (1918); *J. Chem. Soc.* 114, I, 500.—The following compds. have been recognized among the products of the oxidation of cholesterol by HNO<sub>3</sub>: dinitroisopropane, and AcOH, succinic, methylsuccinic and methylglutaric acids. Acetone, hydroxyisobutyric acid, methyl isohexyl ketone, and octane have been previously obtained, and W. points out that all the substances may be regarded as derived from an iso-octyl side chain in cholesterol. On this assumption, cholesterol may be represented by the formula:

C. J. WEST.

Conversion of levulose-diphosphoric acid into the corresponding monophosphoric acid. CARL NEUBERG. *Biochem. Z.* 88, 432–6 (1918); *J. Chem. Soc.* 114, I, 423.—This conversion can be brought about by gentle warming of a salt with N HCl or (CO<sub>2</sub>H)<sub>2</sub>.

The Ca salt of the monophosphoric acid has the formula  $C_6H_{11}O_7PCa.H_2O$ , and the Ba salt  $C_6H_{11}O_7PBa.H_2O$ . The monophosphate can be fermented by living yeast, whereas the diphosphate cannot. C. J. WEST.

**New  $\beta,\beta$ -dialkylglutaric acids.** I. GUARESCHI. *Atti r. accad. sci. torino* 53, 831-41 (1918).—These acids are of importance on account of their relation to the glutaric acid derivs. obtained by the scission of proteins, their isomerism with the higher homologs of  $(CH_2CO_2H)_2$  obtained in the oxidation of fats, and their relation to products obtained from camphor and santonin. The general method (*Atti r. accad. sci. torino* 36, (1901)) consists in the reaction of 1 mol. each of  $RR'CO$  and  $NH_3$  with 2 mols.  $NCCH_2CO_2Et$  to form  $RR'C[CH(CN)CO]_2NH$  and hydrolysis of this to give the  $RR'C(CH_2CO_2H)_2$ . 2 g.  $Pr_3C[CH(CN)CO]_2NH$  were boiled 3 hrs. with 30 cc. 60%  $H_2SO_4$ , solution with effervescence gradually taking place. Cooled, dild. with  $H_2O$ , and extd. with  $Et_2O$ , the mixt. yielded 1.55-1.6 g.  $\beta,\beta$ -dipropylglutaric acid, needles, m. 112-3°, m. under boiling  $H_2O$ ; the vapors cause coughing; a soln. of the  $NH_4$  salt gives microcryst. ppts. in the cold with  $AgNO_3$ ,  $CuSO_4$ , and  $Pb(OAc)_2$ , ppts. with  $ZnSO_4$  and  $FeCl_3$ , and with  $CaCl_2$  only on warming. The zinc salt was analyzed. Neutralization of this and other acids of this type with  $NH_3$  does not result in the liberation of  $C_2H_4$  or the corresponding hydrocarbon, as in the case of the  $\alpha,\alpha$ -dialkylglutaric acids (*Mem. r. accad. torino* 50, II, 268 (1901)) or the  $\beta,\beta$ -dialkyldicyanoglutarimides.  $\beta,\beta$ -Ethylpropylglutaric acid, yield 90%, needles or plates, m. 71-2°; silver salt.  $\beta,\beta$ -Methylisobutylglutaric acid, crystals, in almost quant. yield, m. 63-5°.  $\beta,\beta$ -Methylisohexylglutaric acid, in theoretical yield, crystals, m. 62-3°; silver and zinc salts.  $\beta,\beta$ -Methylnonylglutaric acid, from the dicyanoimide and 20 parts 60%  $H_2SO_4$  for 9 hrs., unctuous plates, m. 46.5-7.5°.  $\beta,\beta$ -Methylhexylglutaric acid, by hydrolyzing the imide for 4.5 hrs. and boiling the crude product again with 5 parts 60%  $H_2SO_4$  for 3 hrs., crystals, m. 52-3°. In passing from the  $Me_2$  to the  $Et_2$  and  $Pr_2$  derivs. an increase in m. p. of 4° is noted in each case. When 1 R is Me and the other increases the m. p. decreases, the MePr compd. being an exception M. HEIDELBERGER.

**A novel application of bromine water in synthetic organic chemistry.** JOHN READ AND MARGARET MARY WILLIAMS. *J. Proc. Roy. Soc. N. S. Wales* 51, 558-64 (1918).—When  $Br.H_2O$  is used as a test for the ethylenic linkage in org. substances, it is usually assumed that a di-Br compd. is the sole product. With  $H_3C:CH_2$ , however, 37.5% of the total Br was found to be converted to  $H_2CBrCH_2Br$ , 54.4% to  $H_2CBrCH_2OH$ , and 8.1% was eliminated as  $HBr$  (from decompn. of the  $HOBr$  formed during the reaction). When  $Br$  vapor was introduced into a soln. of  $PhCH:CHCO_2H$  in 30 times its wt. of ice-cold  $H_2O$ ,  $PhCH(OH)CHBrCO_2H$  (82.9%, relatively) and  $Ph(CHBr)_2CO_2H$  (17.1%) were the products. The latter was sepd. by filtration. The phenyl- $\alpha$ -bromolactic acid, extd. with  $Et_2O$  from the filtrate and crystd. from hot  $H_2O$ ,  $C_6H_6$ , or  $C_7H_8$ , m. 120-2°.  $AgNO_3$  pptd. the  $Ag$  salt from the  $H_2O$  soln. ( $Ag$ , 30.28% obtained; theory 30.68%) and  $Ph(CHBr)_2CO_2H$  added to the  $H_2O$  soln. caused the formation of  $Ph(CH)_2Br$ . When  $PhCH:CHCO_2Na$ , made from soln. of the acid in  $Na_2CO_3$ , was treated with  $Br$ , different results were obtained. A heavy oil and some crystals sepd.; the oil, extd. with light petroleum, was  $Ph(CH)_2Br$  (42.6%) and the crystals,  $Ph(CHBr)_2CO_2Na$  (4.6%). 52.8% of  $PhCH(OH)CHBrCO_2H$  was obtained. This method is a great improvement in prepg. the latter compd. which can be converted into  $PhCH_2CHO$  by treating successively with caustic alkali and dil.  $H_2SO_4$ . The value of the  $Br.H_2O$  method here described is in providing an efficient source of  $Br$  and  $HOBr$  and in connection with the prepn. of synthetic drugs. C. H. KIDWELL.

**Spectral analysis of the plant coloring matters of the flavone group.** I. Y. SHIBATA AND K. KIMOTSUKI. *J. Tokyo Chem. Soc.* 39, 771-808 (1918).—S. and K. studied the absorption spectra of the aq. soln. of flavone, apigenin, luteolin, galangine,

genperide, genperol, quercetin, myricetin, chrysin and their derivs. which show 2 absorption bands in the violet region in 0.0001 *N* soln. They came to the following conclusions: The introduction of a HO group into the benzene ring adjoining the pyrone ring as well as into the position next to the CO in pyrone ring, has a bathochrome effect on the first band  $\lambda = 3000$  in flavone, which is also affected hyperchromatically by the number of HO and MeOH groups in the benzene ring. The second band at 4000 is exhibited by all the compds. and is supposed to be due to the pyrone ring. The authors classified the coloring matters found in 19 plant specimens by applying these rules on the exts. from the plants and also confirmed the position of HO in the mol. of primetine found in *Primula farinosa* L. (yukiwariso) by studying its absorption curves.

S. KOMATSU.

**Synthesis of alkyl benzyl ketones.** III. A. OGATA. *Yakugaku-Zasshi* (J. Pharm. Soc. Japan) No. 441, 855-61 (1918).—By the method described in C. A. 12, 410, prepared *heptyl benzyl ketone*,  $b_{25} 165-9^\circ$ , and *pentadecyl benzyl ketone*, m.  $54-5^\circ$ . *Heptylbenzyl cyanide*,  $b_{21} 222-8^\circ$ ,  $\alpha$ -phenylheptylacetamide, m.  $111-2^\circ$  and *palmityl cyanide*, m.  $172-4^\circ$  and  $\alpha$ -phenylpalmitylacetamide, m.  $109-12^\circ$  were isolated as intermediate products. The yield of the cyanide decreased with increase of mol. wt. of both acids.

S. KOMATSU.

**The chemical constitution of squalene.** B. KUBOTA. *Tokyo Kwagaku Kwaishi* (J. Tokyo Chem. Soc.) 39, 879-907 (1918).—The present study was carried out to det. the constitution of the unsatd. hydrocarbon in shark-liver oil by studying the decompn. products of the ozonide. For this purpose, the material was prepd. from crude oil by Tsuzimoto's method (C. A. 10, 2989; 12, 1004). It  $b_{25} 284-5^\circ$ ,  $d_{15} 0.8596$ ,  $n_D^{15} 1.49595$ . Redistd. at 0.17 mm., it  $b_{0.17} 105^\circ$ ,  $d_{15} 0.86011$ ,  $n_D^{15} 1.4966$ . Through 14 g. pure oil dissolved in 70 cc.  $CHCl_3$ , was passed an  $O_3$ -air mixt. (5-7%) for 10 hrs. and the oil was allowed to stand in an ice-cooled room overnight. The filtrate from succinic acid sepg. in cryst. form was subjected to distn. at low pressure to remove the solvent; it yielded a viscous ozonide which was purified by pptn. with petr. ether, b.  $30-60^\circ$  from its  $Et_2O$  soln. The ozonide  $C_{30}H_{58}(O_3)_8$ , was decompd. with  $H_2O$  and the following substances were isolated from 27 g. oil or 45.95 g. ozonide:  $CO_2$  1.82 g.,  $CH_3O$ ,  $Me_2CO$  1.01, cyclodiacetone superoxide 0.7, levulinic aldehyde 0.68,  $HCO_2H$  0.84, levulinic acid 9.3, succinic acid 8.35, acid  $C_8H_{14}O_6$ , m.  $132-4^\circ$ , i.s., acid  $C_6H_{10}O_6$ , m.  $191-2^\circ$ , 0.5; total 24.7 g. From the data above mentioned, the author proposes the formula  $Me_2C:CH(CH_2)_2C(Me):CH(CH_2)_2CH:CH(CH_2)_6CH:CH(CH_2)_2CH:CH(CH_2)_2CMe:CH_2$  for squalene.

S. KOMATSU.

**The action of formic acid upon triarylcarbinols.** ADOLPHE KOVACHE. *Ann. chim.* 10, 184-248 (1918).—K. found that when  $Ph_3COH$  is boiled with pure  $HCO_2H$  it is quant. reduced to  $Ph_2CH$ . In order to ascertain the general applicability of this reaction it was applied to: (1) several derivs. of  $Ph_3COH$ ; (2) diphenylenphenylcarbinol and its derivs. (3) phenylxanthidrol and derivs. thereof; (4) some carbinols belonging to different groups of compds.; and (5) to some  $CH_2Ph_2$  and  $CHPh_3$  compds. It was found that whereas all of the compds., but one, of (1) were reduced quant. with  $HCO_2H$ , most of the others were so reduced only after the addition of  $HCO_2Na$ . In two cases, however, even the addition of  $HCO_2Na$  failed to give quant. results. The following compds. of group (1) were quant. reduced by means of  $HCO_2H$ : *o*- and *p*-methyl-, *p,p'*-dimethyl-, *p,p',p''*-trimethyl-, *o*-chloro-, *p*-methoxy- and *m*-nitrotriphenylcarbinols.  $1-C_{10}H_7CPh_2OH$  was quant. reduced only after the addition of  $HCO_2Na$ . Of groups (2) and (3), the following compds. were quant. reduced by boiling  $HCO_2H$  and  $HCO_2Na$ : 9-phenyl-, 9-*p*-tolyl-, 9-*p*-methoxy-, 9,1-naphthyl- and 9-benzylfluorenols and -xanthenols. Of group (4) the following were quant. reduced: 10-hydroxy-9,9,10-triphenyl- and 9,10-dihydroxy-9,10-diphenyl-9,10-dihydroanthra-

cenes and triphenylhydroxy- $\alpha,\alpha'$ -benzo- $\beta,\beta'$ -dihydro- $\alpha,\alpha'$ -furfurane. Benzhydrol even after 5 hrs. boiling was not completely reduced. Of group (5),  $(\text{Me}_2\text{NC}_6\text{H}_4)_2\text{CHOH}$  was reduced quant.;  $(p\text{-Me}_2\text{NC}_6\text{H}_4)_2\text{CH}$  broke down quant. into 1 mol.  $\text{PhNMe}_2$  and 1 mol.  $(\text{Me}_2\text{NC}_6\text{H}_4)_2\text{CH}_2$ ;  $(p\text{-Me}_2\text{NC}_6\text{H}_4)_2\text{CHPh}$  did not react quant. with  $\text{HCO}_2\text{H}$  and  $\text{HCO}_2\text{Na}$ ,  $\text{PhNMe}_2$  and  $\text{Me}_2\text{NC}_6\text{H}_4\text{CH}_2\text{Ph}$  being identified as the reaction products;  $(p\text{-Me}_2\text{NC}_6\text{H}_4)_2\text{COH}$  was reduced quant., whereas  $(p\text{-Me}_2\text{NC}_6\text{H}_4)_2\text{CHOH}$  was not. In this entire investigation the quantitative estimations were made by absorbing with  $\text{KOH}$  and weighing the  $\text{CO}_2$  produced by the oxidation of the  $\text{HCO}_2\text{H}$ . No general satisfactory explanation of the favorable action of  $\text{HCO}_2\text{Na}$  is given. M. PHILLIPS.

**Manufacture of picric acid.** ALEXANDER MURRAY. *Color Trade J.* 4, 5-8(1919).—Fair yields of picric acid may be obtained under a variety of very flexible conditions. Under war conditions the process became standardized and may be carried out in small or large units, the latter being more economical in every way, and yields a more uniform product. In small units, nitrating pots of 60 to 70 gals. capacity are placed in batteries in such a manner that they can be warmed by steam pipes. Fifty lbs. of phenoldisulfonic acid are placed in each nitrator, dild. with 25 lbs. of  $\text{H}_2\text{O}$  with stirring, and covered. By means of a glass tube passing through the cover and dipping below the surface of the liquid, 90 lbs. of 75%  $\text{HNO}_3$  are run in slowly. A brisk reaction follows with the evolution of much red fumes and the temp. rises to  $115\text{--}20^\circ$ . At times foaming is troublesome, being caused by impurities in the acid used in sulfonating the phenol. By lab. control this source of loss may be avoided. The pots should be kept hot for 3 to 6 hrs. When fumes cease to come off the acid siphons are removed and the picric acid is stirred with a wooden paddle at hr. intervals as long as the temp. remains above  $108^\circ$ . Eight or 10 hrs. after nitration,  $\text{H}_2\text{O}$  is added and the dild. spent acid siphoned out and run to the concn. plant, while the crystals of picric acid are washed and dried in a centrifuge to 8% moisture. Large installations consist of a sulfonating tank holding, for example, 4166 lbs. of 92.7%  $\text{H}_2\text{SO}_4$  and 1000 lbs. of phenol, and provided with inlet pipes for steam coils, water, and air (for stirring). The mixt. is kept well agitated at  $50$  to  $70^\circ$  for 12 or, better, 24 hrs. For this reason it is best to have two sulfonators for each nitrator. Complete sulfonation is detd. by lab. test; then 2650 lbs. of  $\text{H}_2\text{O}$  is added with strong agitation and the mixt. is cooled to  $40\text{--}5^\circ$ . (Sulfonation may be effected with less  $\text{H}_2\text{SO}_4$  than given above, 2.5 to one phenol instead of 4 to 1 being used, and the amt. of  $\text{H}_2\text{O}$  changed in proportion.) The watered disulfonic acid and 5560 lbs. of mixed acid containing 15%  $\text{H}_2\text{SO}_4$  and 65%  $\text{HNO}_3$  are fed together into a mixing funnel from which they enter the nitrator. This requires about 2.5 hrs. Violent ebullition ensues, the temp. rising to  $114\text{--}9^\circ$ . The temp. is controlled by the amt. of  $\text{H}_2\text{O}$  previously added to the phenoldisulfonic acid. It is very important to use correct proportions, as the picric acid melts if the temp. goes above  $120^\circ$ , and gives a lumpy product. About an hour later the charge is stirred at intervals to prevent caking. The charge should be kept warm as long as possible and should stand at least 12 hrs. The contents of the nitrator are dild. with water, the spent acid is siphoned off and the picric acid washed and dried by the usual methods for handling large quantities. The  $\text{H}_2\text{SO}_4$  recovered by concg. the spent acid is not pure enough for sulfonation of the phenol, but can be used for other purposes about the plant. L. W. RIGGS.

**Identification of acids. IV. Phenacyl esters.** J. B. RATHER AND E. EMMET REID. *J. Am. Chem. Soc.* 41, 75-83(1919); cf. C. A. 11, 2579.—In addition to the *p*-nitrobenzyl esters described in the earlier papers, the phenacyl esters of a number of org. acids have now been prepd. in the hope that they also might be of use in the identification of acids, a hope which has been justified by expt. The presence of the ketone group in the esters gave promise that phenylhydrazones, oximes, semicarbazones, etc.,

might be prepd. and afford further means of identification; it was found, however, that the phenylhydrazones are not readily formed and that the oximes are difficult to purify and have low m. ps.; the semicarbazones have not yet been studied. The "reagent" used in the prepn. of the esters, *vis.*,  $\text{PhCOCH}_2\text{Br}$  (the chloride reacts much more slowly and gives lower yields), prepd. essentially by Möhlau's method (*Ber.* 15, 2464 (1882)), is obtained in 25–30 g. yield by slowly adding 28 g. Br to 20 g. BzMe in 30 g. glacial AcOH, pouring into ice water after the mixt. has begun to cool, letting stand 1 hr. and crystg. from alc.; it m.  $50^\circ$ . To prep. the esters slightly more than 0.005 equiv. acid and a little less than the equiv. amt. of  $\text{Na}_2\text{CO}_3$  are dissolved in hot  $\text{H}_2\text{O}$ , 1 g. of the bromide and 10 cc. of 95% alc. added and the heating is continued under a reflux 1, 2 and 3 hrs. for mono-, di- and tribasic acids, resp. (more alc. being added if necessary to prevent the ester from sepg. out); the soln. is then cooled rapidly under the tap and the crystals are filtered off with suction, washed twice with 5-cc. portions of alc. of the same strength as the reaction mixt. and then twice with  $\text{H}_2\text{O}$ . Recrystn. was repeated until const. m. ps. were obtained. The following *phenacyl esters* were so prepd.: Acetate, m.  $40^\circ$ ; aconitate, m.  $90^\circ$ ; *o*-aminobenzoate, m.  $181-2^\circ$ ; benzoate, m.  $118.5^\circ$ ; *p*-bromobenzoate, m.  $87^\circ$ ; cinnamate, m.  $140.5^\circ$ ; citraconate, m.  $108.5^\circ$ ; citrate, m.  $104^\circ$ ; *m*-cresotate, m.  $116.5^\circ$ ; *o*-cresotate, m.  $138.5^\circ$ ; *p*-cresotate, m.  $145.5^\circ$ ; fumarate, m.  $197.5^\circ$ ; glutarate, m.  $104.5^\circ$ ; itaconate, m.  $79.5^\circ$ ; lactate, m.  $96^\circ$ ; malate, m.  $106^\circ$ ; maleate, m.  $119^\circ$ ; mandelate, m.  $84.5^\circ$ ; *p*-nitrobenzoate, m.  $128.4^\circ$ ; palmitate, m.  $52.5^\circ$ ; pyrotartrate, m.  $101.5^\circ$ ; saccharate, m.  $120^\circ$ ; salicylate, m.  $110^\circ$ ; stearate, m.  $64^\circ$ ; succinate, m.  $148^\circ$ ; tartrate, m.  $130^\circ$ . Formic, butyric, valeric and oleic acids gave oily products; no ester of  $(\text{CO}_2\text{H})_3$  could be prepd. from either the Na, K or  $\text{NH}_4$  salt; asparaginic and gallic acids yielded gums, and naphthionic acid gave no satisfactory result. Attempts to prep. phenylhydrazones from the benzoate, salicylate, valerate and butyrate (from the ester and  $\text{PhNHNH}_2$  in hot alc.) yielded products m.  $132-5^\circ$  which were apparently all Hess' tetraphenyltetra-carbazone (*Ann.* 232, 235(1886)) in varying degrees of purity, the esters evidently reacting with the  $\text{PhNHNH}_2$  with splitting off of the acid radical. The *oxime* of the benzoate seps. from petr. ether in needles, m.  $92^\circ$ ; the oximes of the formate, cinnamate and mandelate are oils. These oximes are very sol. in the usual org. solvents except petr. ether. C. A. ROUILLER.

**Synthesis of aminoflavones, of flavoneazo- $\beta$ -naphthol dyes and of other flavone derivatives.** MARSTON TAYLOR BOGERT and JOSEPH K. MARCUS. *J. Am. Chem. Soc.* 41, 83–107(1919).—When  $\text{PhC:CCO}_2\text{Et}$  (a) is added to a "warm" ( $60-70^\circ$ ) mixt. of  $\text{PhONa}$  and  $\text{PhOH}$  (Ruhemann, *Ber.* 24, 2582(1891)), the  $\text{PhONa}$  only partially dissolves and the product, which distils over a wide range ( $140-215^\circ$  under 12 mm.), smells of (a), but with (a),  $\text{PhONa}$  suspended in xylene and an excess of  $\text{PhOH}$  at  $140-50^\circ$ , the product, treated by R.'s method, gives 2 fractions: (b), 10 g.,  $b_{18} 203-16^\circ$ , and (c), 116.1 g.,  $b_{18} 216-9^\circ$ , m.  $37-45^\circ$ . On sapon. with alc. NaOH, (c) gives not 1, but 2 acids: (d), 8 g., sepg. first from alc. in broad prisms, and then (e), 49 g., needles. After repeated crystn. from alc. (e) softened  $126^\circ$  and m.  $139-40^\circ$  (gas evolution) and proved to be fairly pure  $\text{PhOCPh:CHCO}_2\text{H}$ . (d) after similar treatment softened  $169^\circ$ , m.  $176-7^\circ$ , gave tests for a phenol HO group with Liebermann's reagent and with  $\text{TiO}_2$  in  $\text{H}_2\text{SO}_4$  gave no color with aq. or alc.  $\text{FeCl}_3$  dissolved in concd.  $\text{H}_2\text{SO}_4$  with bright yellow color and decolorized Br in  $\text{CHCl}_3$ ; B. and M. believe it to be  $\beta$ -*o*- or *p*-hydroxyphenylcinnamic acid. Flavone (f) was obtained essentially by R.'s method from (e) in 85% yield. In its nitration all attempts to limit the action to the formation of only 1 mono- $\text{NO}_2$  deriv. failed; 60.5 g. (f) in 60 cc. AcOH and 180 cc.  $\text{H}_2\text{SO}_4$  treated with 32 cc. AcOH- $\text{HNO}_3$  (0.58 g.  $\text{HNO}_3$  (d. 1.5) per cc.), allowed to stand in the ice-box 3 days and poured into ice-water, gave 69 g. of faint yellow ppt. sepd. by crystn. from AcOH into 39 g., m.  $175-206^\circ$ , of a mixt. of the 3'- and 4'-nitroflavones (g),

and 19 g., m. 143-68°, of a mixt. of the 2'- and 3'-nitro compounds (h). These were not isolated individually but converted into the NH<sub>2</sub> derivs. which were sepd. by means of their different basicities and solubilities. 2'-Amino-*flavone*, obtained in 7 g. yield from 19 g. (h) by reduction with SnCl<sub>2</sub> and HCl in alc., silky, pale yellow needles from Me<sub>2</sub>CO, m. 149.5-150.5°, gives a positive isonitrile test, sol. without color in cold concd. H<sub>2</sub>SO<sub>4</sub>, in concd. HNO<sub>3</sub> with yellow color, reduces cold KMnO<sub>4</sub> in dil. H<sub>2</sub>SO<sub>4</sub>, gives a black amorphous ppt. with K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> in warm dil. H<sub>2</sub>SO<sub>4</sub>. 4'-Amino-*flavone*, from (g), long golden yellow needles from xylene, m. 234-6°, imparts to iso-AmOH, glycerol and EtOH an intense bluish green, to Et<sub>2</sub>O, Me<sub>2</sub>CO, AcOEt, AcOAm and C<sub>6</sub>H<sub>5</sub>N an intense blue, to MeOH and PhOH a faint green fluorescence, to CHCl<sub>3</sub>, C<sub>6</sub>H<sub>6</sub>, PhMe, xylene, ligroin, CCl<sub>4</sub> and AcOH no fluorescence; in Et<sub>2</sub>O free from H<sub>2</sub>O and alc. there is no trace of fluorescence but the addition of a drop of EtOH or H<sub>2</sub>O at once produces an intense blue fluorescence. In those solvents in which fluorescence does not occur (C<sub>6</sub>H<sub>6</sub>, etc.) a considerable amt. of a solvent containing a HO group must be added before the fluorescence is brought out (e. g., 0.5 cc. iso-AmOH to 5 cc. C<sub>6</sub>H<sub>6</sub>). In H<sub>2</sub>O, the absence of fluorescence is probably due to the insoly. of the amine; in AcOH, to the neutralization of the NH<sub>2</sub> group. The amine dissolves with yellow color in MeOH, EtOH, AcOEt, AcOH and without color in the other solvents; light yellow colors are obtained by impregnating wool and silk in HCl solns. of the HCl salt and developing the color in dil. Na<sub>2</sub>CO<sub>3</sub>. 3'-Amino-*flavone*, lemon-yellow needles from xylene, m. 156-7°, gives light yellow colors on wool and silk. 2'-Diacetyl-*amino-*flavone**, oblong prisms from alc., m. 186.5-7.5°, sol. without color in concd. H<sub>2</sub>SO<sub>4</sub>; 3'-isomer, hair-like needles from Me<sub>2</sub>CO, m. 231-2°; 4'-compound, hair-like needles from alc., m. 246-8°. 2'-Hydroxy-*flavone*, from the NH<sub>2</sub> deriv. through the diazonium compd., plates from alc., m. 249-50°, slowly sol. in cold concd. H<sub>2</sub>SO<sub>4</sub> with greenish yellow color and slight green fluorescence, sol. in cold dil. or hot concd. NaOH. 3'-Isomer, narrow plates, m. 207-8°. 4'-Compd., needles from alc., m. 269-70°. 2'-Acetoxy-*flavone*, long, thin needles from dil. alc., m. 88.5-9°; 3'-compd., long needles from dil. alc., m. 97-8°; 4'-compd., needles from dil. alc., m. 136°. With NaOEt the above HO compds. give *o*-HOC<sub>6</sub>H<sub>4</sub>Ac and *o*-, *m*- and *p*-HOC<sub>6</sub>H<sub>4</sub>CO<sub>2</sub>H, resp. *Flavone-2'-azo-β-naphthol*, from the 2'-amine and β-naphthol through the diazonium compd., hair-like orange-red needles from AcOH, m. 265-6.5° (decompn.), sol. in cold H<sub>2</sub>SO<sub>4</sub> with reddish purple color. 3'-Isomer, flat, crimson prisms from AcOH, m. 257° (decompn.), sol. in H<sub>2</sub>SO<sub>4</sub> with deep wine-red color. 4'-Compound, dark red needles from AcOH, m. 274-5° (decompn.), sol. in H<sub>2</sub>SO<sub>4</sub> with deep purple color. The 2'- and 3'-compds. gave bright orange colors on silk and duller orange shades on wool, while the 4'-compd. gave red colors; cotton, however, even when previously impregnated with turkey-red oil, took the dyes unevenly. The dyed materials are very fast to light and alkalis but are dulled by 2% AcOH. Methyl β-bromohydrocinnamate, from the acid, MeOH and HCl, thick prisms from petr. ether, m. 37.5-8.5°. β-Phenoxyhydrocinnamic acid (i), obtained in 10.4 g. yield from 30 g. PhCHBrCH<sub>2</sub>CO<sub>2</sub>H and 13 g. dry PhOH in 50 cc. C<sub>6</sub>H<sub>6</sub> kept 2 hrs. at 85-90°, long, silky needles from C<sub>6</sub>H<sub>6</sub>, m. 150-1°, sol. in dil. Na<sub>2</sub>CO<sub>3</sub>; the NH<sub>4</sub> salt gives ppts. with the nitrates of Cd, Cu<sup>+</sup>, Pb and Ag but not with salts of Na, K, Ca, Ba, Bi, Co or Fe<sup>++</sup>. From the C<sub>6</sub>H<sub>6</sub> filtrate from the above acid, by removing the PhOH with steam, dissolving the residual oil in Et<sub>2</sub>O and extg. with Na<sub>2</sub>CO<sub>3</sub>, were obtained PhCH:CHCO<sub>2</sub>H and 1.4 g. white needles from PhMe, m. 151.5-2.5°, which are believed to be *p*-HOC<sub>6</sub>H<sub>4</sub>CHPhCH<sub>2</sub>CO<sub>2</sub>H (Liebermann, *Ber.* 24, 2582), while the Et<sub>2</sub>O, after the extn. with Na<sub>2</sub>CO<sub>3</sub>, yielded 8.2 g. β-phenylhydrocoumarin, m. 81.5-2°, b<sub>40</sub> 243°. In attempting to convert (i) into flavanone by heating 6.7 g. of it with 60 g. concd. H<sub>2</sub>SO<sub>4</sub> 1 min. at 130-5°, it was found that the product was a disulfo-β-phenoxyhydrocinnamic acid, isolated as the barium salt [Ba(O<sub>2</sub>S)<sub>2</sub>C<sub>6</sub>H<sub>4</sub>CH(OPh)CH<sub>2</sub>CO<sub>2</sub>]<sub>2</sub>

Ba.5.5H<sub>2</sub>O, thin, broad microplates from H<sub>2</sub>O and alc. (yield, 4 g.), gives ppts. with salts of Bi, Cr'', Co, Ag, Sn'', but not with those of Na, K, Ca, Ba, Al, Cd, Cu'', Fe'', Pb, Mg, Mn, Hg'', Ni or Zn. Attempts to effect the condensation of (i) to flavanone with other dehydrating agents or of its chloride with AlCl<sub>3</sub> likewise failed. 2-Nitroflavanone is obtained rapidly but in poor yield (2%) by heating 25 g. PhCHBrCH<sub>2</sub>CO<sub>2</sub>H and 15.5 g. *p*-O<sub>2</sub>NC<sub>6</sub>H<sub>4</sub>OH 30 min. in 30 cc. C<sub>6</sub>H<sub>6</sub> at 80–5°; it seps. from AcOH in long, silky needles, m. 144–4.5°, insol. in NaOH and Na<sub>2</sub>CO<sub>3</sub>, does not reduce alk. KMnO<sub>4</sub> in the cold and reduces it only slowly on boiling. All m. ps. given above are cor.

CHAS. A. ROUILLER.

**Influence of catalysts on the chlorination of hydrocarbons.** V. R. KOKATNUR. *J. Am. Chem. Soc.* 41, 120–4 (1919).—A number of expts., in which (CHCl<sub>3</sub>)<sub>2</sub> containing various catalysts (vegetable charcoal, animal charcoal, Fe, bleaching powder, AlCl<sub>3</sub>) was treated with Cl, are described briefly. C<sub>2</sub>Cl<sub>4</sub> was obtained in every case, but C<sub>2</sub>HCl<sub>3</sub> in none.

CHAS. A. ROUILLER.

**Action of chlorine upon hydrazine, hydroxylamine and urea.** C. T. DOWELL. *J. Am. Chem. Soc.* 41, 124–5 (1919).—In the course of a study of the action of Cl on urea, D. obtained evidence that in the reaction of Cl with NH<sub>2</sub>OH and N<sub>2</sub>H<sub>4</sub> NCl<sub>3</sub> is formed; if the reaction is allowed to take place in the presence of CCl<sub>4</sub> and the CCl<sub>4</sub> layer is afterwards treated with KI N is evolved. Chattaway (*Chem. News* 98, 285 (1902)), who isolated dichlorourea from the reaction product of Cl and urea, observed that solns. of this compd. on standing decomp., giving NCl<sub>3</sub> as one of the products; he supposed that the reaction took place between dichlorourea and H<sub>2</sub>O, with formation of CO<sub>2</sub> and NH<sub>4</sub>Cl and that the latter decompd. into NH<sub>3</sub> and NCl<sub>3</sub>. D. has tested the soln. for NH<sub>2</sub>Cl by Raschig's method (NH<sub>3</sub> + BzH) with negative results, and concludes that the NCl<sub>3</sub> is formed by the action of Cl which is itself probably a decompn. product of the dichlorourea.

CHAS. A. ROUILLER.

**The linear phenonaphthacridonequinone and quinacridonequinone.** W. ST. LENSIAŃSKI. Techn. Hochschule, Lemberg. *Ber.* 51, 695–706 (1918).—The 2 compds. were prepd. to det. whether acridone-like quinones are vat dyes. Phenonaphthacridonequinone (I), reduced with alk. Na<sub>2</sub>S<sub>2</sub>O<sub>4</sub>, yields a blue vat dye giving orange-yellow shades on cotton, but the yellow-orange quinacridonequinone (II) does not normally give a vat dye, for the dark green alkali salt of its leuco deriv. is almost insol. in H<sub>2</sub>O. The blue-violet NH<sub>2</sub> derivs. of these 2 substances show markedly the characteristics of vat dyes. The 2 quinones have pronounced salt-forming properties, surpassing, in this respect, the ordinary acridones. Anilino- $\alpha$ -naphthoquinone-*o*-carboxylic acid (III), obtained in 95% yield by gently boiling for some time equal amts. of  $\alpha$ -naphthoquinone and *o*-H<sub>2</sub>NC<sub>6</sub>H<sub>4</sub>CO<sub>2</sub>H in alc., red needles from AcOH or alc., m. 271°, sol. in alc. and AcOH with red, in Et<sub>2</sub>O, AcOEt and C<sub>6</sub>H<sub>6</sub> with orange-yellow, in concd. H<sub>2</sub>SO<sub>4</sub> with cherry-red color, pptd. unchanged from the last solvent by H<sub>2</sub>O. The deep red alk. soln., when boiled for a time and then treated with an excess of HCl, gives 2-hydroxy-1,4-naphthoquinone. Silver salt, from the K salt and AgNO<sub>3</sub> in H<sub>2</sub>O, amorphous, dark red ppt. When warmed a short time at 140–50° in about 10 parts concd. H<sub>2</sub>SO<sub>4</sub> and then poured upon ice, (III) gives 70–5% of (I), purified by conversion into the K salt, decompn. with HCl and crystn. from AcOH; (I) forms a yellow-orange powder subliming in orange needles, m. 384°, forms non-fluorescent solns. Potassium salt, red micro-needles with 1 H<sub>2</sub>O from the orange solns. of (I) in dil. KOH. If a slightly warmed soln. of (I) in HNO<sub>3</sub> (d. 1.4) is cautiously dild. with H<sub>2</sub>O the nitrate (I).2HNO<sub>3</sub>, seps. in light yellow needles slowly losing their HNO<sub>3</sub> and becoming orange. A yellow cryst. sulfate and yellow needles of a hydrochloride can be obtained in the same way. CrO<sub>3</sub> ppts. dirty yellow flocks from the AcOH soln. of (I). (I) gives no bisulfite compd., is not reduced by SO<sub>2</sub>, does not react with PhNHNH<sub>2</sub> and forms no azine with *o*-C<sub>6</sub>H<sub>4</sub>-

( $\text{NH}_3$ ). On distn. with Zn dust it yields linear dihydrophenonaphthacridine, m.  $285-6^\circ$  (Schöpf, *Ber.* 27, 2841 (1894)). *Dihydrophenonaphthacridonequinone*, from (I) and  $\text{Na}_2\text{S}_2\text{O}_4$  in boiling alc., red-violet powder, m.  $317^\circ$ , quickly changes back into (I) in the air, forms in alkalis blue solns. which in the air deposit the red salt of (I); boiled 3 hrs. with  $\text{Ac}_2\text{O}$  and  $\text{NaOAc}$ , it yields an *acetyl derivative*, orange needles from  $\text{AcOH}$ , m.  $292^\circ$ , insol. in cold alkalis but easily sapond. on heating. *Dinitrophenonaphthacridonequinone*, obtained in 2 g. yield by cautiously warming 2.6 g. (I) in 25 cc.  $\text{H}_2\text{SO}_4$  for 1 hr. with 2 cc. fuming  $\text{HNO}_3$  (d. 1.52) and 5 cc.  $\text{H}_2\text{SO}_4$ , yellow microcryst. powder from  $\text{PhNO}_2$ , m.  $299^\circ$ , sol. in alkalis with red color; with little alk.  $\text{Na}_2\text{S}_2\text{O}_4$  it first gives a violet color (probably owing to the formation of the di- $\text{NH}_2$  deriv.) and with more  $\text{Na}_2\text{S}_2\text{O}_4$  dissolves with blue-green color, the soln. depositing in the air a red-violet ppt. of the presumed di- $\text{NH}_2$  compd. Crude (II) is obtained in 80% yield as a brown, compact mass by heating benzoquinonedianthranilic acid (a) with 15-7 parts concd.  $\text{H}_2\text{SO}_4$  20 min. at  $145-55^\circ$ ; owing to its insoly. in org. solvents it can be purified only by rubbing 10 g. to a paste with a little alc., dilg. with  $\text{H}_2\text{O}$  to 1 l., pouring 100 cc. of the resulting suspension into 1.5-1.0 boiling  $\text{H}_2\text{O}$ , treating, with continuous stirring, with 10-2 g.  $\text{KOH}$  in 100 cc.  $\text{H}_2\text{O}$  and filtering hot; on cooling the *potassium salt* seps. in red microneedles from which the free (II) is obtained by decompn. with dil.  $\text{AcOH}$ . It can also be purified through the cryst. sulfate; 5 g. (a) in 50 cc. concd.  $\text{H}_2\text{SO}_4$  are heated to  $150^\circ$  and poured into 550 cc. cold dil.  $\text{H}_2\text{SO}_4$  (d. 1.53); the sulfate seps. in 2.5 g. yield and by repeated boiling with  $\text{H}_2\text{O}$  is converted into the free (II) (about 1 g.). (II) is an amorphous, yellow powder, sublimes partly in dark orange needles, carbonizes above  $530^\circ$  without melting, sol. with orange color in hot alkalis of suitable concn., almost insol. in concd. alkalis and in alc.  $\text{KOH}$ , sol. in concd.  $\text{H}_2\text{SO}_4$  and in fuming  $\text{HNO}_3$  with orange color, insol. in concd.  $\text{HCl}$ . The *monopotassium salt*, red needles with 1  $\text{H}_2\text{O}$ , cannot be obtained absolutely pure as an excess of alkali is required to dissolve the (II) and some of the *dipotassium salt* seps. along with the former; the latter seps. in amorphous, brown-yellow flocks with 1  $\text{H}_2\text{O}$ . Both salts are extremely easily hydrolyzed by traces of  $\text{H}_2\text{O}$  and even of alc. *Nitrate*, (II). $4\text{HNO}_3$ , from 1 g. (II) in 25 cc. fuming  $\text{HNO}_3$  (d. 1.52) treated with 20 cc. dil.  $\text{HNO}_3$  (d. 1.333) and allowed to cool, golden yellow needles, quickly loses about 0.5 of its  $\text{HNO}_3$  in the air, turning red. *Sulfate*, (II). $3\text{H}_2\text{SO}_4$ , leaflets, becomes red when moistened with  $\text{H}_2\text{O}$  and changes to a yellow powder on boiling. (II) is unchanged by 18 hrs. heating at  $180^\circ$  in a sealed tube with 1:1  $\text{HCl}$ , is attacked by alkalis only on fusion; boiling  $\text{Ac}_2\text{O}$  yields only a very minute amt. of a dark red sol. product sol. in alc. with red color and eosin-like fluorescence;  $\text{AcCl}$ ,  $\text{BzCl}$  and  $\text{Me}_2\text{SO}_4$  give no sol. products;  $\text{NH}_4\text{OH.HCl}$  (in alc. at  $180^\circ$ ) and  $\text{PhNHNH}_2$  do not react with it. The alc. suspension treated with cold aq.  $\text{Na}_2\text{S}_2\text{O}_4$  gives the *leuco compound* as a blue-violet mass, very difficultly sol. in  $\text{Ac}_2\text{O}$  with violet, sol. in concd.  $\text{H}_2\text{SO}_4$  with blue color;  $\text{H}_2\text{O}$  ppts. it from the latter apparently unchanged in violet flocks; in the air these solns. turn through green into yellow-orange; the solid, especially if moist, undergoes the same oxidation back to (II); dil. alkalis dissolve it with light green color, the solns. quickly depositing the salt of (II) in the air. With alk.  $\text{Na}_2\text{S}_2\text{O}_4$  (II) gives a dark green flocculent ppt. and a faintly green soln. *Dinitroquinacridonequinone*, from 1.5 g. (II) in 30 cc. fuming  $\text{HNO}_3$  boiled gently 1.5 hrs., pptd. with  $\text{H}_2\text{O}$ , washed, dried and again heated 1.5-2.0 hrs. with fuming  $\text{HNO}_3$ , light yellow, insol., infusible powder, forms red stable alkali salts, gives no compds. with acids; with alk.  $\text{Na}_2\text{S}_2\text{O}_4$  it turns through violet into green-blue, yielding a liquid and a ppt. of the same color; in the air the soln. deposits the violet, presumably di- $\text{NH}_2$  deriv. *Potassium salt*, dark red powder with 2  $\text{H}_2\text{O}$ . *Dihydroquinacridine*, obtained in 0.6 g. yield by distg. about 80 g. (II) in 2-2.5 g. portions each with 25-30 g. Zn dust heated to redness in H under 200-300 mm., dark red

microcryst. powder with metallic luster from  $C_6H_6$ , m.  $379^\circ$ , sol. in hot alc. with red-dish yellow color and strong greenish yellow fluorescence, in AcOH with violet, in concd.  $H_2SO_4$  with violet-blue color, unattacked by concd.  $HNO_3$ ,  $CrO_3$ , etc.; HCl ppts. the blue-violet hydrochloride from alc. The  $C_6H_6$  mother liquors from the dihydro compd. yield a very small amt. of a brown-olive basic substance, m. above  $450^\circ$ , converted by acids into intensely green salts. All m. ps. given above are cor.

CHAS. A. ROUITLER.

**Influence of foreign substance on the activity of catalyzers. IV. Experiments with palladium hydrosol in the presence of mercury and mercuric oxide.** C. PAAL AND WILHELM HARTMANN. Univs. Erlangen and Leipzig. *Ber.* 51, 711-37(1918); *d. C. A.* 8, 1902.—Hg and HgO, the latter more rapidly, permanently destroy the catalytic power of colloidal Pd towards detonating gas and in catalytic hydrogenations; this paralysis of the catalyzer is brought about by Hg and HgO in the colloidal state much more rapidly than in the metallic or pptd. form, and it has been found that without exception the Pd hydrosol colloiddally dissolves the Hg by peptization, the HgO by chem. action, and it is only in this form that the Hg and HgO develop their specific action as strong contact poisons. The Pd hydrosols used in the expts. had been previously employed in gas burets with Hg as the confining liquid for catalyzing detonating gas or reducing org.  $NO_2$  and unsatd. compds. or had undergone a preliminary treatment with H or O or these 2 gases alternately in the presence of Hg, and on testing these Pd preps. with detonating gas or easily reducible  $NO_2$  and unsatd. compds. it was found that they had become passive in both types of reaction; this passivity, however, is specific and limited to these 2 reactions; towards  $H_2O_2$  the Pd sols. rendered inactive by Hg and HgO are strongly catalytic. The soln. of metallic Hg by the Pd hydrosol takes place only slowly and the decrease in catalytic activity of the Pd progresses parallel with the soln. of the Hg until, when a certain amt. (varying with different sols) has been taken up the Pd is completely paralyzed; the amts. of Hg necessary for this are directly proportional to the strength of the catalytic effect of the Pd sol. As the Hg is taken up not only in the presence of O but also in a H atm. on long contact with the Pd sol (this process is hastened by shaking) it can be present only in elementary form and, as has been found, in an acid-insol. and non-diffusible, i. e., colloidal form. That the process cannot be a purely mechanical "peptization" favored by the colloidal mixt. of Pd sol and Na protalbinat present is shown by the fact that solns. of Na protalbinat shaken a long time with metallic Hg do not take up the slightest trace of the metal. HgO is dissolved much more rapidly and in greater amt. and also in a non-diffusible form. If the process takes place in H there is a partial reduction of the HgO, for when a Pd sol rendered inactive in this way is treated with dil. HCl it gives a ppt. of colloidal Pd and free protalbinic acid containing elementary Hg in the same form as by direct treatment of metallic Hg with Pd hydrosol. The greater part of the Hg dissolved from the pptd. HgO by the Pd sol, however, is found in the HCl filtrate as  $HgCl_2$  and must therefore have been present in the Pd sol in an acid-sol. form. Since, as found experimentally, pptd. HgO, contrary to metallic Hg, is dissolved colloiddally by shaking with an aq. soln. of Na protalbinat, there occurs here apparently not only a peptization as the result of mechanical action but also a chemical process resulting in a colloidal salt-like combination, decompd. by HCl, of the HgO with the Na protalbinat. That the anti-catalytic action of the HgO is not due exclusively to the elementary Hg produced by

its reduction and dissolved by the Pd is shown by the fact that a Pd hydrosol completely paralyzed by shaking with pptd. HgO in a H atm. and then freed of the sol. portion of the Hg by pptn. with HCl recovers a part of its original activity. P. and H. conclude that the anticatalytic effect of Hg and HgO are due to their destruction of the power of Pd hydrosol to adsorb H and that therefore they inhibit all those catalytic processes effected by adsorption of H, like the catalysis of detonating gas and catalytic hydrogenations and dehydrogenations, but not the catalytic decompn. of  $H_2O_2$ . CHAS. A. ROUILLER.

**Bromoalkylated aromatic amines. III. Derivatives of ethylenediamine.** J. v. BRAUN AND E. MÜLLER. Univ. Techn. Hochschule, Warschau. *Ber.* 51, 737-41 (1918); cf. C. A. 12, 2557.— $\omega$ -Bromoethyl derivs.,  $PhNRCH_2CH_2Br$ , of sec. aromatic bases condense with sec. amines easily to form ethylenediamine derivs. of the type  $PhNRCH_2CH_2NR'R''$  in which  $R'$  and  $R''$  may be aromatic or aliphatic groups. By nitrosating the Ph nuclei and hydrolyzing the NO compds., it is possible to obtain purely aliphatic ethylenediamine derivs. of the types  $RNHCH_2CH_2NHR'$  and  $RNHCH_2CH_2NR'R''$  with the same or different alkyl groups on the 2 N atoms. *Dinitroso-N,N'-diphenyl-N,N'-dimethylethylenediamine monohydrochloride*, obtained quant. by nitrosating the diamine, fine green-brown powder, m.  $153^\circ$ ; free base, bright green, m.  $108^\circ$ . Boiled 0.5 hr. with 40 parts  $NaHSO_3$  soln. (d. 1.21), acidified with HCl, concd. to 0.5 its vol., made strongly alk. and distd. with steam, the distillate being collected in dil. HCl, the NO compd. gives 80-8%  $(CH_3NHMe.HCl)_2$ , m.  $235-6^\circ$ ; free base, m.  $120^\circ$ . *N-Methyl-N'-ethyl-N,N'-diphenylethylenediamine*, obtained almost quant. by warming 10 hrs. on the  $H_2O$  bath  $PhNMeCH_2CH_2Br$  and about 3 mols.  $PhNHEt$  or  $PhNEtCH_2CH_2Br$  and the corresponding amt. of  $PhNHMe$ , almost colorless and odorless, thick liquid,  $b_{21}$   $232-4^\circ$ ; *picrate*, fine crystals from alc., m.  $176^\circ$ ; *p,p'-dibromo derivative*, obtained by bromination in AcOH, needles from alc., m.  $100^\circ$ . The *dinitroso compound*, fine yellow-green powder, m.  $190^\circ$ , gives with  $NaHSO_3$  *N-methyl-N'-ethylethylenediamine*, isolated as the *dihydrochloride*, very hygroscopic, m.  $217-8^\circ$ ; *chloroplatinate*, m.  $240^\circ$ ; the free base is a mobile liquid of the same odor as the di-Me compd., b.  $133^\circ$ , fumes in the air with absorption of  $CO_2$  and moisture. Nitrosation of  $PhNMeCH_2CH_2NMe_2$  (C. A. 12, 1391), even in the presence of excess of HCl and on long standing, does not result in the sepn. of a difficultly sol. HCl salt; by making the soln. alk. with soda the crude free base itself is obtained as a dark oil which is extd. with  $Et_2O$  and, after removal of the  $Et_2O$ , is hydrolyzed to  $MeNHCH_2CH_2NMe_2$  (a). The (a).2HCl obtained in this way and described in the first paper was not pure; it has now been obtained pure by treating it with very concd. NaOH, extg. 3 times with  $Et_2O$ , drying a short time, treating with excess of picric acid, boiling the picrate with not too much abs. alc. and filtering hot; the yellow, finely cryst. portion remaining undissolved proves to be the pure *picrate*,  $C_{17}H_{20}O_4N_8$ , m.  $209-10^\circ$ ; this, treated with alkali, extd. with  $Et_2O$  and pptd. with HCl and  $Et_2O$ , gives the pure *dihydrochloride*, m.  $183^\circ$ ; *chloroplatinate*, long, pointed, yellow-red needles from a little  $H_2O$ , darkens  $225^\circ$ , m.  $230^\circ$  (decompn.); the free base b. about  $140^\circ$ . CHAS. A. ROUILLER.

**Attempt to synthesize fisetol. Preliminary communication.** J. TAMBOR AND EDMOND M. DuBOIS. Univ. Bern. *Ber.* 51, 748-51 (1918).— $\omega$ -Bromoresacetophenone methyl ether (a), 2,4-HO(MeO) $C_6H_3$ COCH $_2$ Br, prisms from alc., m.  $92^\circ$ , difficultly volatile with steam, is obtained by slowly treating in the cold 40 g.  $AlBr_3$  in 40 g.  $BrCH_2COBr$  with 50 g.  $m-C_6H_4(OMe)_2$  in 100 g.  $CS_2$ , letting stand 3 days at room temp., protected from moisture, decanting the solvent from the resinous product, washing several times with  $CS_2$ , decompg. with ice, removing the unchanged  $C_6H_4(OMe)_2$  with steam and placing the oily residue in a freezing mixt. In the same way is obtained  $\omega$ -chlororesacetophenone dimethyl ether, needles from  $C_6H_6$ , m.  $119^\circ$ . (a) boiled a long

time with concd. aq. KI gives the *ω*-iodo compound, very faintly, yellow, prisms from dil. alc., m. 102°. With  $\text{Ac}_2\text{O}$  and  $\text{H}_2\text{SO}_4$  (a) gives the acetate  $\text{AcO}(\text{MeO})\text{C}_6\text{H}_4\text{COCH}_2\text{Br}$ , needles from alc., m. 83°, probably identical with Friedländer's brominated acetylpeanol, m. 86–7° (*Ber.* 30, 301 (1897)), whereas acetylation of (a) in small amts. with  $\text{Ac}_2\text{O}$ - $\text{NaOAc}$  gives 4-methylfisetyl diacetate, 2,4- $\text{AcO}(\text{MeO})\text{C}_6\text{H}_2\text{COCH}_2\text{OAc}$ , scales from alc., m. 86°, which on short warming with alc. KOH yields fisetyl 4-methyl ether, scales from alc., m. 128°. This, if a method of dealkylation can be discovered, should give fisetol.

C. A. ROULLER.

**$\beta$ -Naphthylsulfur chlorides.** TH. ZINCKE AND K. EISMAYER. Marburg. *Ber.* 51, 751–67 (1918).— $\beta\text{-C}_{10}\text{H}_7\text{SH}$  (a),  $b_p$  153–4°, is obtained in 75–80% yield by treating 80 g. crude  $\beta\text{-C}_{10}\text{H}_7\text{SO}_3\text{Cl}$  in 400 cc. alc. and 2 cc. concd. HCl with 70 g. Zn dust in small portions, below 40°, stirring 30–45 min. longer, warming gradually, again adding 70 g. Zn dust, then 100 cc. concd. HCl with continuous shaking, heating on the  $\text{H}_2\text{O}$  bath under a reflux until a portion pptd. with  $\text{H}_2\text{O}$  dissolves clear in alkali (more Zn dust and acid being added if necessary but too long boiling being avoided), pouring hot into 1.5 l.  $\text{H}_2\text{O}$  acidified with HCl, boiling the residue up twice with alc. HCl, filtering, dissolving in  $\text{Et}_2\text{O}$  and drying with  $\text{Na}_2\text{SO}_4$ . Treated with Cl in 10 parts, glacial AcOH it gives a ppt. of the disulfide which redissolves and on further treatment with Cl is converted into  $\text{C}_{10}\text{H}_7\text{SO}_3\text{Cl}$ , but if 5 g. in 30 cc. dry  $\text{CHCl}_3$ , protected from moisture, is treated with 1 mol. Cl, allowed to stand some time, evapd. *in vacuo* and dried on clay over  $\text{H}_2\text{SO}_4$  there is obtained  $\beta$ -naphthylsulfur chloride,  $\text{C}_{10}\text{H}_7\text{SCl}$ , yellow-red cryst. powder, m. 50–60°, quickly becomes colorless on standing, with loss of Cl and HCl and formation of the disulfide chiefly with small amts. of a faintly green product; with alkalis, alc.,  $\text{Me}_3\text{CO}$ ,  $\text{PhNH}_2$ ,  $\beta$ -naphthol, it gives the disulfide. 1-Chloronaphthyl-2-sulfur chloride (b), obtained in 6 g. yield from 5 g. (a) in 40 cc. dry  $\text{CHCl}_3$  treated with the Cl evolved with 4 g.  $\text{KMnO}_4$ , yellow-red crystals from hexane, m. 74–5°, stable and very reactive; treated in 8–10 parts AcOH with Cl to disappearance of the yellow-red color it gives 1,2- $\text{C}_{10}\text{H}_6\text{ClSO}_2\text{Cl}$ , thick needles from benzene, m. 84–5°; with dry NaOMe in hexane it forms the ester  $\text{ClC}_{10}\text{H}_6\text{S.OMe}$ , unstable, almost colorless oil, decomp. in a few hrs. in the air into the disulfide and disulfoxide and is converted back into (b) by concd. HCl; 10 g. in 150–60 cc. benzene shaken 20–30 min. with 200 cc. of *N* soda gives di-1-chloronaphthyl-2-sulfur oxide,  $(\text{ClC}_{10}\text{H}_6\text{S})_2\text{O}$ , bright yellow crystals from PhMe, m. 149° (blackening), converted back into (b) by  $\text{PCl}_5$ , decompd. by hot alkalis into the disulfide and the sulfinic acid and by boiling AcOH into the disulfide and the disulfoxide. Di-1-chloronaphthyl-2-disulfide, slender leaflets from AcOH, m. 141–2°, sol. in concd.  $\text{H}_2\text{SO}_4$  without color. 1-Chloronaphthyl-2-sulfinic acid, felted needles from AcOH, m. 138–9° (blackening): methyl ester, prepd. through the Ag salt, long needles from MeOH, m. 139–40°, identical with the sulfone prepd. from 1,2- $\text{C}_{10}\text{H}_6\text{ClSMe}$ . Di-1-chloronaphthyl 2-disulfoxide, also obtained from (b) and the Ag salt of the  $\text{SO}_3\text{H}$  acid in boiling  $\text{C}_6\text{H}_6$ , prismatic needles from  $\text{C}_6\text{H}_6$ -benzene, m. 152–3°, liberates I from KI in AcOH, decompd. by boiling alkalis into the disulfide and  $\text{SO}_3\text{H}$  acid. 1-Chloronaphthyl-2-sulfuramine,  $\text{ClC}_{10}\text{H}_6\text{SNH}_2$ , obtained by adding 5 g. (b) in 50–60 cc.  $\text{Et}_2\text{O}$  to 50 cc. of 25%  $\text{NH}_4\text{OH}$  (covered with a layer of  $\text{Et}_2\text{O}$ ), washing the  $\text{Et}_2\text{O}$  layer with  $\text{H}_2\text{O}$ , evapg. *in vacuo*, dissolving in cold MeOH and pptg. with  $\text{H}_2\text{O}$ , short, thick needles from benzene, easily becoming reddish, reddens 95°, begins to decomp. 105–10°, m. about 160°, decompd. by cold concd. HCl into (b), converted by dil. HCl or glacial AcOH into the imine, gives with 1 part  $\text{BzH}$  and 15 parts MeOH after 24 hrs. the compound  $\text{ClC}_{10}\text{H}_6\text{SN:CHPh}$ , pptd. by  $\text{H}_2\text{O}$  from alc. in needles, m. 106–7°. Di-1-chloronaphthyl-2-sulfurimine,  $(\text{ClC}_{10}\text{H}_6\text{S})_2\text{NH}$ , also obtained by passing an excess of dry  $\text{NH}_3$  into a 1:10 soln. of (b) in  $\text{Et}_2\text{O}$  and purified by heating to boiling with 4 parts  $(\text{CHCl}_3)_3$ , adding 2 vols.  $\text{C}_6\text{H}_6$ , filtering hot

and washing with hot  $C_6H_6$ , faintly colored cryst. powder, m.  $213-4^\circ$ , stable towards cold, concd. HCl but decompd. on heating into the disulfide and disulfoxide, sol. in concd.  $H_2SO_4$  (decompn.) with blue-black color. *1-Chloronaphthyl-2-sulfurethylamine*, from 2 g. (b) in 20 cc.  $Et_2O$  added to 3 cc. of 30% aq.  $MeNH_2$ , leaflets from  $MeOH-H_2O$ , m.  $89-90^\circ$ , decompd. by concd. HCl into (b), converted by dil. HCl, better by glacial AcOH, into the *methylimine*,  $(ClC_{10}H_6S)_2NMe$ , also obtained by adding 3 cc. of 30%  $MeNH_2$  to 2 g. (b) in 40 cc.  $Et_2O$ , leaflets from  $C_6H_6$ -benzine, m.  $177-8^\circ$ , stable towards cold concd. HCl, profoundly decompd. on heating, slowly decompd. by boiling AcOH, chiefly into the disulfide. *1-Chloronaphthyl-2-sulfuranilide*, from (b) in  $C_6H_6$  warmed with somewhat more than 2 mols.  $PhNH_2$ , prismatic needles from benzine, m.  $132^\circ$ , decompd. by concd. HCl chiefly into the disulfide and disulfoxide.  *$\alpha$ -Naphthalide*, crystals from  $C_6H_6$ -benzine, m.  $154^\circ$ , gives a red dye with  $PhN_2Cl$ . *2,4-Di-[1'-chloronaphthyl-2'-sulfur]- $\alpha$ -naphthylamine*,  $(ClC_{10}H_6S)_2C_{10}H_6NH_2$ , from (b) in 10 parts hot AcOH treated with 0.5 part  $\alpha$ - $C_{10}H_7NH_2$  in 6 parts AcOH, crystals from  $EtOH-H_2O$ , m.  $85-7^\circ$ , can be diazotized in AcOH and yields a red dye with  $\beta$ -naphthol; *acetyl derivative*, prepd. with  $Ac_2O-NaOAc$ , needles from AcOH, m.  $144-5^\circ$ . *1-Chloronaphthyl-2-sulfur- $\beta$ -naphthalide*, needles, m.  $132-3^\circ$ , decompd. by concd. HCl; 1 g. boiled a short time with 10 cc. AcOH and 1 cc. AcOH satd. with HCl is converted into the isomeric  *$\alpha$ -1-chloronaphthyl-2-sulfur- $\beta$ -naphthylamine*, also obtained directly by warming (b) with 20 parts AcOH and 0.65 part  $\beta$ - $C_{10}H_7NH_2$ , prisms and needles from  $C_6H_6$ -benzine, m.  $183-4^\circ$ , can be diazotized in AcOH and gives with  $\beta$ -naphthol a red dye; *diacetyl derivative*, needles from AcOH, m.  $153-4^\circ$ . The amine boiled a short time with 0.5 mol. (b) in  $C_6H_6$  (20 parts for every part (b)), gives the compound  $1,2-C_{10}H_6(SC_{10}H_6Cl)NHSC_{10}H_6Cl$ , slender needles from  $C_6H_6$ -benzine, m.  $187-8^\circ$ , which on warming with AcOH-HCl easily loses the  $SC_{10}H_6Cl$  group attached to the N. *1-Chloronaphthyl p-dimethylaminophenyl 2-sulfide*, from (b) in 5 parts  $C_6H_6$  warmed a short time with 2 mols.  $PhNMe_2$ , prisms and needles from benzine, m.  $120-1^\circ$ , has faintly basic properties.  *$\alpha'$ -[1-Chloronaphthyl-2-sulfur]- $\alpha$ -naphthol*,  $1,4-C_{10}H_6(OH)SC_{10}H_6Cl$ , from (b) in 12 parts  $C_6H_6$  boiled with 1 mol.  $\alpha$ -naphthol to disappearance of the red color, needles from  $MeOH-H_2O$ , m.  $116-8^\circ$ , sol. in warm N alkali, partially sepg. again on cooling or dilg., converted by oxidizing agents (Br and alkalis) into a blue-green substance; *acetyl derivative*, crystals from benzine, m.  $138-9^\circ$ .  *$\beta$ -Naphthol isomer*,  $2,1-C_{10}H_6(OH)SC_{10}H_6Cl$ , from (b) and  $\beta$ -naphthol intimately mixed 10-5 min. on the  $H_2O$  bath, needles from  $C_6H_6$ -benzine, m.  $142-3^\circ$ , unchanged by hot  $PhNH_2$  or quinoline, gives no naphthoxine with HCl, sol. in alkalis, repptd. by diln.; *acetyl derivative*, needles from benzine, m.  $123-4^\circ$ . *[1'-Chloronaphthyl-2'-sulfur]-4-resorcinol*,  $1,3,4-C_6H_3(OH)_3SC_{10}H_6Cl$ , from 4 g. (b) and 2 g.  $m-C_6H_4(OH)_2$  boiled 3-4 hrs., in 50 cc.  $C_6H_6$ , leaflets from  $C_6H_6$ -benzine, m.  $153-4^\circ$ , sol. in dil. alkalis; *diacetate*, needles from benzine, m.  $83-4^\circ$ . *[1-Chloronaphthyl-2-sulfur]acetone*,  $ClC_{10}H_6SCH_2Ac$ , from (b) heated with  $Me_2CO$  until the color has almost disappeared, needles from  $C_6H_6$ -benzine, m.  $70-1^\circ$ ; *phenylhydrazone*, leaflets, m.  $202^\circ$ . *1-Chloronaphthyl 2-thiocyanate*, from (b) and 0.5 part KCN in 15 parts hot AcOH, crystals from benzine, m.  $118-9^\circ$ .

The bitter principles of hops (WÖLLMER) 16. Miscibility of phenol and aqueous solutions of alkalies (DUBRISAY, *et al.*) 2.

**Phenanthraquinone.** H. F. LEWIS and H. D. GIBBS. U. S. 1,288,431, Dec. 17. Phenanthraquinone is formed by oxidation of vapors of phenanthrene with air at temps. of 300-500° (preferably about 400°) in the presence of a catalyst which may be  $V_2O_5$  or some other oxide of a metal of the fifth or sixth periodic group.

**Anthraquinone.** CHEMISCHE FABRIK GRIESHEIM-ELEKTRON. Swed. 44,184, June 26, 1918. In the treatment of anthracene with  $HNO_3$  below 60° and subsequently at a higher temp., in the presence of a solvent or diluent and Hg salts, Cl is introduced to decompose organic Hg compds.

**Citric acid.** H. TOBLER. U. S. 1,288,293, Dec. 17. Impure Ca citrate is treated with  $NaHSO_4$  to form Na citrate and  $CaSO_4$ . The  $CaSO_4$  is sepd. from the soln. and the latter is then heated with sufficient lime to neutralize free acidity and with sufficient  $CaSO_4$  to complete the reaction and ppt. Ca citrate. The latter is then sepd. from the soln., which retains the impurities, and decomposed to obtain pure citric acid.

**Alcohol.** ELEKTIZITÄTSWERK LONZA. Brit. 120,163, Mar. 16, 1918. In the manuf. of alc. by treating acetaldehyde vapor with H in the presence of a catalyst, the H is employed in large excess over the theoretical quantity; this gives a product containing little aldehyde or undesirable by-products and also serves to take up the heat developed in the reaction. The excess of H, after removal of the alc., is returned to the reaction vessel. Cf. C. A. 12, 2326.

**Fate of starch grains injected into the circulation.** K. OKASAKI. *Chugai Iji Shimpo* No. 900, 1134-5(1917); *Jap. Med. Literature* 3, 72-3(1918); cf. C. A. 12, 374.—Taro starch, suspended in saline, was injected into the ear vein of rabbits, which were then killed after various intervals of time had elapsed. Their organs were examd. for starch emboli, and for diastatic change in the starch. Practically all the starch was caught in the lung, by lodgment in the capillaries or by the phagocytes, occasionally by newly formed giant cells. Evidence of diastatic action was found on all the grains only after 36 days. A similar series of exts. was made, in which the starch suspension was injected into the portal vein, and examn. made of the liver. Starch lodged in the Kupffer cells underwent change in a few days; that lodged in the periphery of the lobules changed

more slowly. The phagocytic cells exerted a diastatic action on the starch particles within their influence.

JOSEPH S. HEFURN.

**Enzyme studies. I. Ptyalin.** W. BIEDERMANN. *Fermentforschung* 1917, No. 1, 385-436; *Z. angew. Chem.* 1917, No. 90, 345; *Biedermanns Zentr.* 47, 279-80 (1918).—The very great diastatic power of saliva is noteworthy. B. speaks of an almost explosive decompn. With regularly increasing dilns. of the soln. of enzyme its action is retarded by approx. equal periods of time from which the conclusion is drawn that the time necessary for the decompn. of starch to dextrin by ptyalin is inversely proportional to the quantity of enzyme; also that the figures giving the diastatic power of the enzyme soln. (*i. e.*, the quantities of starch decomposed by 1 cc. of undild. saliva in a definite time) are directly proportional to these times. Sugar formation does not proceed parallel with dextrin formation but is slower as the amt. of enzyme diminishes. It may be regarded as certain that the hydrolysis of starch by the ptyalin of human saliva, and consequently by diastatic enzymes, takes place in steps since dextrin formation reaches a certain stage before maltose can be formed. This phenomenon can only be explained by the supposition that diastatic enzymes consist of 2 components, an amylase which splits the starch mol. to dextrans and a "dextrinase" which attacks the dextrin. The diastatic enzyme is not absolutely resistant to boiling, yet the diastatic power cannot be destroyed by mere boiling. On repeated addition of starch to the boiled enzyme soln. a regeneration of enzyme (if not a new formation of diastase) took place. Samples thus strengthened immediately lose their newly acquired diastatic power when boiled for a very short time. B. believes that the new formation of enzyme from starch under the influence of the salts of saliva ash is proved by his expts. **II. The autolysis of starch.** *Idem.* *Wochschr. Brau.* 1917, No. 34, pp. 183-6.—See C. A. 11, 1436.

A. 12, 1990.—When the brains of rabbits and guinea pigs which had died of rabies were washed with physiol. NaCl soln. and immersed in neutral, sterilized glycerol the rabic virus passed into non-rabic brains, liver and kidney immersed in the same liquid in contact with the rabic brains.

H. S. PAINE.

**Biophotogenesis and natural synthesis of luciferin.** RAPHAEL DUBOIS. *Compt. rend. soc. biol.* 81, 317-9 (1918); cf. C. A. 12, 1898.—D. proposes the following statement of the essential known facts of biophotogenesis with the following hypothesis to explain these facts: A thermolabile substance (luciferase) exhibiting the general characteristics of enzymes (and especially oxydones) produces physiol. luminescence in the presence of O and H<sub>2</sub>O *in vitro* by its interaction with a less thermolabile substance (luciferin). Luciferase may be replaced by other oxidizing substances such as KMnO<sub>4</sub>, PbO<sub>2</sub>, etc. This action is no longer produced when the aq. soln. of luciferin has been heated to 70-80° (temp. varying with the compn. of the vehicle); the liquid heated to 100° no longer produces luminescence with KMnO<sub>4</sub>. The characteristic photogenic property of luciferin may reappear in the photogenic mucus heated at 100° if, after cooling, it is placed in contact for several hrs. with the enzyme coluciferase. Since the latter ordinarily accompanies luciferase this is possibly a case of the reversible action of a single enzyme. Coluciferase may be readily extd. by macerating fragments of the luminous organs (*e. g.*, of *Pholas*) in alc. or Et<sub>2</sub>O, rehydrating slightly and then macerating 48 hrs. in neutral glycerol. Luciferase is destroyed by this treatment; luciferin is not sol. in glycerol and only coluciferase is found therein. This liquid (A) does not produce luminescence with KMnO<sub>4</sub>. The alc. or Et<sub>2</sub>O ext., when filtered and evapd., leaves a turbid aq. soln. This liquid (B) after filtration gives no more luminescence than (A) with the oxidizing agents mentioned. The property of producing luminescence

after addition of  $\text{KMnO}_4$  reappears when (A) and (B) are mixed, dild. with 2 parts of  $\text{H}_2\text{O}$ , and allowed to stand 10–12 hrs. (B) contains a substance which is provisionally termed "preluciferin." This result may be produced by substances (e. g., Byla peptone, lecithin, taurine, tyrosine, asparagine, esculin) other than soln. (B) These substances, and doubtless others, probably contain a nucleus which interacts with coluciferase again to produce preluciferin. The latter is then transformed by the oxidizing action of luciferase. This reaction of oxyluminescence takes place in 2 stages as shown by the following expt: When  $\text{PbO}_2$  is added to a soln. of luciferin luminescence is quickly produced. When this luminous mixt. is filtered there is obtained a clear, luminous liquid which contains no trace of Pb. This liquid contains a substance, termed "oxyluciferin," which is spontaneously oxidizable in the presence of free O only. The succession of the various phases of bioluminescence may be represented, viz., (1) coluciferase + preluciferin = luciferin; (2) luciferase + luciferin = oxyluciferin; (3) oxyluciferin + O = light. These various relations explain the results obtained by Harvey, particularly when he mixes certain non-oxidizing substances or exts. of non-photogenic organs or non-luminescent organisms with a spontaneously extinguished photogenic liquid. Products of incomplete oxidation such as taurine which are present in abundance in *Pholas dactylis* serve for the renewed production of luciferin and oxyluciferin and this cycle explains the great production of light by insects such as the *Pyrophori* which are capable of producing light for several days with access only of  $\text{H}_2\text{O}$  and air and without excretion of either solid or liquid. The above facts may also be applied to greater or less extent to the explanation of more fundamental phenomena of plant and animal nutrition such as enzymic synthesis of proteins. H. S. PAINE.

**Peroxidases.** RICHARD WILLSTÄTTER AND ARTHUR STOLL. *Ann.* 416, 21–64 (1918); *J. Chem. Soc.* 114, I, 555–7.—W. and S. have set themselves the task of so improving the methods of isolating and purifying enzymes that the following questions may be answered: (1) whether enzymic activity is possessed by an analytically pure compound or whether an "enzyme" is a system of coöperating substances; (2) whether a metal is an integral part of an enzyme; and eventually, (3) what atomic groupings are associated with enzyme activity. As a preliminary study, the case of horse-radish peroxidase has been chosen. For the isolation of highly concd. peroxidase preps., the following scheme is recommended: (a) Thin slices of the roots (5 kg.) are kept for a few days in flowing water in order to remove the simpler products by dialysis through the cell walls. (b) The washed material is digested with oxalic acid soln. (40 g. to 10 l.) for a few hrs. By this means, the regulating influence of the living protoplasm is removed, the peroxidase is pptd., apparently adsorbed on coagulated protein material, and dialysis proceeds further, mustard oil being extd. in large quantities. So extensive is the dialysis, that the dried slices lose more than 25% in wt. and half of their mineral matter. (c) The material is crushed in a mill, washed on a filter with about 15 l. of  $\text{H}_2\text{O}$  containing 1.5 g. of oxalic acid, and then thoroughly pressed free from sap. The residue (1.5 kg.) is intimately triturated with  $\text{Ba}(\text{OH})_2$ , almost sufficient to overcome its acidity, then pressed again, and now treated with further quantities of  $\text{Ba}(\text{OH})_2$  to liberate the enzyme. Most of the Ba is retained by the fibers, but the expressed liquid is just acidified by  $\text{CO}_2$  to remove the remainder, and then the filtrate is mixed with 0.9 of its vol. of alc. Slimy substances are pptd. and the filtrate is evapd. to 50–70 cc. *in vacuo* from a bath at  $50^\circ$ . The residue is filtered again, and then mixed with 5 vols. of alc., whereby the crude enzyme is pptd. This is purified a little more by redissolving it in water containing a trace of  $\text{H}_2\text{SO}_4$  and repptg. it by alc. (d). The crude material is found to be a mixt. of the enzyme with a nitrogenous glucoside, which can be pptd. as a compd. with  $\text{HgCl}_2$ . Accordingly, an aq. soln. is treated with 0.5%  $\text{HgCl}_2$  and a trace of  $\text{CaCl}_2$  to coagulate the jelly-

like double compd., the mass is filtered, and the enzyme is reprecipitated by alc. from the filtrate. The peroxidase is then dissolved in  $H_2O$ , whereby some of the  $HgCl_2$  compd. remains undissolved, the clear soln. obtained by centrifuging is reprecipitated by alc. and the process repeated until the enzyme dissolves clearly in  $H_2O$ . The best prepn. obtained so far amounted to 0.45 g. from 5 kg. of horse radish, this representing about 60% of the enzyme originally present. The glucoside compd. is decomposed by 2 *N* HCl and the glucoside obtained by precipitating the soln. with alc. amounts to 3.4 g. In order to control the above operations, a method for estimating peroxidase was developed. It depends upon the production of purpurogallin from pyrogallol and  $H_2O_2$ , but is free from certain errors which are present in Bach and Chodat's method (*Ber.* 37, 1342(1904)). It is found that peroxidase is not only spoiled by too great a concn. of H-ions, but by too concd.  $H_2O_2$ , and it is only fair, therefore, in devising an analytical method, to choose conditions under which the enzyme is not impaired. The method proposed is as follows: A soln. of 5 g. of purest pyrogallol in 2 l. of  $H_2O$  is mixed with about 10 cc. of 5%  $H_2O_2$  containing exactly 50 mg. of  $H_2O_2$ , regulated to 20° in a thermostat, and then treated with 1-5 cc. of a soln. of 5 mg. of the enzyme in 100-500 cc.  $H_2O$  (that is, from about 0.25 mg. of the crude prepn. to about 0.02 mg. of the best prepn.). After exactly 5 min., the action is stopped by adding 50 cc. of dil.  $H_2SO_4$ , and the purpurogallin is extracted with  $Et_2O$  and estimated colorimetrically by comparison with a soln. containing 100 mg. of the pure pigment in 1 l. of  $Et_2O$ . The results are then translated into the no. of mg. of purpurogallin which would be produced by 1 mg. of the vacuum-dried prepn. This is called the 'purpurogallin number.' For example, the no. for the well pounded horse radish is 0.25, for the crude prepn. before treatment with  $HgCl_2$  about 360 and for the best specimen yet obtained about 670. In a soln. of  $CO_2$ , the enzyme is not impaired but produces about half as much purpurogallin as in pure  $H_2O$ . It appears as though the particular grouping in the enzyme at which the  $H_2O_2$  may be attached is also capable of uniting with acids. Solns. of the preps. which have not been purified by  $HgCl_2$  become somewhat more active after a few hours, but the solns. of the purified enzyme deteriorate. Consequently, any comparisons of activity are made immediately after dissolving the preps. The yield of purpurogallin obtainable from pyrogallol has often been discussed. For instance, Nierenstein and Spiers obtained 10-16%. If the pyrogallol soln. is concd., the amt. of peroxidase employed is large, and the  $H_2O_2$  is added very slowly, so that it is always present in very low concn., the yield may be as high as 80%. Some reactions and analytical data concerning the purest enzyme and its companion glucoside are also recorded. The enzyme appears to consist chiefly of a nitrogenous glucoside, containing a pentose (above 30%) and an equimol. quantity of another sugar, probably a hexose. It does not seem to be very complex, and if it contains only the residues of the 2 sugar mols., its mol. wt. would be about 500 and no. of N atoms 3. It also contains about 5.5% of mineral ash, consisting of alkaline earths and Fe. The amt. of the latter is very small (0.46% of the best prepn.) but it rises with the purification of the enzyme. It is unlikely, however, that Fe plays any stoichiometrical part in the production of purpurogallin, for it may be calculated that the activity of the best prepn. would mean the consumption of 297-355 mols. of  $H_2O_2$  in 1 sec. for every atom of Fe present. Furthermore, the addition of Fe salts has no influence on the reaction. The companion nitrogenous glucoside, which is precipitated by  $HgCl_2$ , is a high-mol. compd. Its vapors give the pyrrol reaction, and it also gives the Millon and xanthoproteic reactions. It contains about 50% of pentose residues and a hexose, and the proportion of N is about 3 atoms to every 2 pentose mols. Oxyhemoglobin has often been compared with peroxidase and Wolff and de Stoëcklin have even stated that they do not differ in peroxidative activity. This is chiefly because rich peroxidase preps.

had not been employed hitherto, for oxyhemoglobin is only about 0.001 part as active as a quantity of peroxidase containing the same amt. of Fe. Fe compds., such as the tannate or a ferrocyanide or sulfate, are also very feeble in their activity as compared with peroxidase.

The isolation, purification and concentration of immune bodies; a study of immune hemolysin. M. KOSAKI. Tokyo, Japan. *J. Immunology* 3, 109-29(1918).—The reversibility of the antigen and amboceptor union is proved to be practically complete so far as the immune hemolysin of the rabbit against sheep blood is concerned. The isolation of hemolytic amboceptor from its antigen union is accomplished by a simple method. When the hemolytic power of the original immune serum is 1:10,000 it is dild. 100 times with physiol. salt soln., and 5 cc. of this dild. serum are poured into 4 cc. of blood cells, which are washed free from serum protein with physiol. salt soln. After 15 to 20 min. at room. temp. all of the hemolytic amboceptor has been absorbed by blood cells, and the antigen-amboceptor union is thus obtained. After the sensitized corpuscular sediment is washed with physiol. salt soln. several times till the last trace of serum protein has been removed, this pure antigen-amboceptor combination is mixed with an isotonic or slightly hypertonic aq. soln. of saccharose, glucose or lactose and left at 55° for 15-30 mins., during which the vessel is shaken several times. The sugar ext. which contains nearly all of the hemolysin used to sensitize the cells is obtained by centrifugation. In order to purify this sugar ext., which contains substances from destroyed blood cells, it is placed in a separatory funnel and shaken for 1 to 2 hrs. with 5-10 vol. of ether, repeating this treatment until the soln. is colorless. This colorless soln. is dialyzed in parchment against running water to eliminate the sugar and traces of NaCl. The soln. thus obtained is concd. *in vacuo* to the required vol.

GEO. T. CALDWELL.

A note on bleeding guinea pigs and on preserving sheep erythrocytes. J. J. WENNER. Yale Univ. *J. Immunology* 3, 389-93(1918).—The animal is suspended from a support by means of a cord fastened to its hind legs and at once held by its head with the left hand. A cut is made over the jugular vein with scissors and the vein partly severed. The bleeding quickly stops when the animal is placed on its back. Freshly washed sheep corpuscles are dild. with an equal quantity of saline soln. To this suspension formalin is added in the proportion of one part of formaldehyde to 500 parts of the suspension. The formalinized washed corpuscles are well shaken and placed in the ice box, where they are well preserved for two weeks, and furnish a ready supply of erythrocytes for complement fixation work.

A convenient dilution chart of use in serologic and other tests in which varying quantities of reagents are employed. L. B. TABER. Berkeley, Calif. *J. Lab. Clin. Med.* 4, 138-40(1918).

GEO. T. CALDWELL.

A new indicator for direct reading of hydrogen-ion concentration in growing bacterial culture. J. BRONFENBRENNER. Harvard Univ. *J. Med. Res.* 39, 25-32 (1918).—As indicator a mixt. of china blue and rosolic acid is used. On account of its slow response to hydrogen-ion concn. this indicator cannot be used for ordinary titrations without the application of heat, in which case readings are made only after cool-

ing. This indicator is prepd. by mixing equal parts of 0.5% aq. soln. of china blue with 1% soln. of rosolic acid in 95% alc. The mixt. can be added directly to media and permits direct estimation of H-ion concn. in the culture at all times. Even in concn. 25 times that present in the media the indicator shows no trace of bactericidal action.

GEO. T. CALDWELL.

**A modification of Webster's test for the presence of T. N. T. in urine.** F. TUTIN. *Lancet* 1918, II, 554.—The urine is first extd. with two successive portions of  $\text{Et}_2\text{O}$ . It is acidified with  $\text{HCl}$  or  $\text{H}_2\text{SO}_4$  and again extd. with  $\text{Et}_2\text{O}$ . The ethereal ext. of the acidified urine must then be extd. twice with dil. aq.  $\text{Na}_2\text{CO}_3$ , washed with water and then treated with alc.  $\text{KOH}$ , when the characteristic violet color will be produced if derivs. of T. N. T. were present.

M. HEIDELBERGER.

**Localization of morphine in the human body.** HENRI MARCELET. Chem. lab. of the 15th Region. *Bull. sci. pharmacol.* 25, Pt. 2, 292-5(1918).—Report of colorimetric tests on the organs of an addict, using the Stas-Otto-Dragendorff technic to isolate the alkaloid. The reagent of Boutmy, Brouardel, and Gautrelet (no ref.) permits a rough approximation of the relative amt. of morphine in the organs, the following results being obtained: Liver, ++++; stomach, +++; kidneys, +++; heart, +; brain, +; lungs, +.

M. HEIDELBERGER.

**Demonstration of indican in the urine by a new method.** K. TAKEUCHI. *Tokyo Igakukai Zasshi* 31, No. 19, 1-36(1917); *Jap. Med. Literature* 3, 74(1918).—The reagent is an aq. soln. containing 8.3 g.  $\text{KI}$ , 8 g.  $\text{I}$ , 6 g.  $\text{KBr}$  in each 100 cc. The urine (5 cc.) is treated with  $\text{Pb}$  acetate, then mixed with several drops  $\text{AcOH}$ , 2 to 3 cc.  $\text{CHCl}_3$ , 1 to 3 drops of the reagent, and shaken several times; 5 to 6 cc. concd. fuming  $\text{HCl}$  are added, and the soln. is shaken; the  $\text{CHCl}_3$  layer is drawn off, washed with  $\text{H}_2\text{O}$  to remove acid, then treated with a few drops  $\text{Na}_2\text{S}_2\text{O}_3$  soln. to remove  $\text{I}$ . The indigo blue, produced from the indican, colors the  $\text{CHCl}_3$ ; the method may be made the basis of a colorimetric detn. of indican. Alk. urine must be acidified with  $\text{AcOH}$  before the test is applied; otherwise the indigo, when formed, will be decomposed by the  $\text{I}$  and alkali.  $\text{I}$  is a more suitable oxidizing agent than  $\text{Cl}$ ,  $\text{Br}$ ,  $\text{CrO}_3$ , and  $\text{H}_2\text{O}_2$  in this reaction, since it converts all the indoxyl into indigo but does not carry the oxidation further. The method was sufficiently delicate to demonstrate the presence of indican in the first urine of a new-born child, and in the *liquor amnii* of 5 cases which were examd. In the presence of strong oxidizing agents, Obermayer's reagent was found to convert from 10 to 20% of the indican into isatin.

**Determination of sugar in milk and urine.** B. SJOLLEMA. Utrecht, Holland. *Chem. Weekblad* 15, 1483-5(1918).—The author calls attention to and describes the method of Folin and Dennis (*C. A.* 12, 1061) and cites the results of analyses to show that the method gives the same results as the longer "Codex" method.

WITHROW MORSE.

**Determination of uric acid in urine.** A. ANGIOLANI. *Boll. chim. farm.* 57, 223 (1918).—The method described contains no new features and does not appear to be accurate.

H. S. PAINE.

**Isotonic solutions.** E. I. VAN ITALLIE. Dutch Army. *Bull. sci. pharmacol.* 25, Pt. 2, 257-63(1918); cf. *C. A.* 12, 1104.—Since Schroeder (*Pharm. Weekblad* 1900, 600) very little has been published on the subject. Articles by Zotier (*C. A.* 11, 3080) and Lumiere and Chevrolier (*Soc. Therap. Paris*, Dec., 1913) are discussed and criticized. If the depression of the f. p. of a soln. is less than  $0.555^\circ$  it may be made iso-

tonic by adding the calcd. amt. of NaCl to bring the depression in the f. p. to this value. This may also be done less accurately, but sufficiently so for practical purposes, by the following calcs., using morphine hydrochloride (A) as example. The calcd. depression for 1 mol. substance in  $H_2O$  is  $18.6^\circ$ . Assuming (A) to be completely dissociated, the f.-p. depression of a 1% soln. of (A) will be  $(18.6 \times 2)/375.5 = 0.099^\circ$ . This, subtracted from  $0.555^\circ$ , leaves  $0.456^\circ$ , and to obtain this depression with NaCl (mol. wt. 58.5) one solves the equation  $0.456 = (18.6 \times 2)/58.5 \times x$ , and  $x = 0.72$  g. per 100 g. soln. By actual expt. 0.76 g. are required. A table is given showing the differences between the observed and calcd. f.-p. depressions of a number of salts commonly used for injection and of the observed and calcd. amts. of NaCl necessary to make these solns. isotonic. The importance of injecting only isotonic solns. is emphasized.

M. HEIDELBERGER.

Color reaction of steapsin on plates of gelose and emulsified fat by production of copper soap. P. CARNOT AND H. MAUBAN. *Compt. rend. soc. biol.* 81, 98-101 (1918).—The following technic is recommended: Prep. a 2:100 agar soln., mix with an equal vol. of 5:100 starch paste, incorporate in this mass about  $1/40$  of its vol. of the neutral fat desired (butter, lard, etc.), heat with const. agitation until a homogeneous emulsion is produced, pour into Petri dishes and cool rapidly. Distribute on the surface of the solidified mass with a fine pipet small drops of the liquid to be tested, keep 1 hr. at  $38^\circ$ , pour a satd. aq.  $CuSO_4$  soln. over the surface, allow to stand 10 mins. and rinse with  $H_2O$ . The presence of steapsin is shown by the appearance of beautiful bluish green spots; the addition of the starch, which is not indispensable, produces a rather white opaque background against which the spots appear very distinct. The use of butter and lard gave particularly good results; castor oil was saponified with difficulty. Intestinal juice (mixed with pancreatic juice and bile) withdrawn direct from the duodenum gave a very distinct positive test; after being heated to boiling it produced only a superficial yellowish stain which was readily removed by  $H_2O$ . This qual. test may be rendered approx. quant. by the method of successive dilns. The steapsin content of various human intestinal juices varied considerably; some gave a positive test when dild. 6-8:100, while others failed to give positive tests when dild. more than 25:100. The content of steapsin generally, but not always, showed a variation parallel to that of trypsin and diastase. Steapsin, probably due to reflux from the duodenum into the stomach, was detected in certain samples of gastric juice. No steapsin was detected in feces, even when passage through the intestines was accelerated by purgation. The official pancreatins of commerce, although rich in diastase and containing considerable trypsin, were found to contain little steapsin, the proportion found being hardly equiv. to the steapsin content of normal duodenal fluid dild. 1:10.

H. S. PAINÉ.

Use of certain reagents for determination of emetine in human urine. CH. MARTEL. *Compt. rend. soc. biol.* 81, 315-7 (1918).—M. studied the action of certain general (Dragendorff, Bouchardat, Tanret, Mayer-Valser) and special reagents. Results obtained by direct examn. of fresh urine free from albumin were unsatisfactory. A modified Milon method was used for extg. emetine, the  $CHCl_3-Et_2O$  ext. from the urine being washed several times, evapd. to dryness and the residue dissolved in 20 cc. of 2:100 HCl. Emetine was detd. quant. by estg. the vol. of ppt. (after centrifuging) or the degree of turbidity (when very small amts. were present) as compared with the corresponding data obtained with solns. containing various known concns. of emetine-HCl. It was possible with the general reagents to det. emetine-HCl when present in the following min. amts. in 5 cc. of liquid, this being the vol. used for comparison in all cases: Tanret, 0.0000125 g.; Mayer-Valser, 0.000025 g.; Dragendorff, 0.00005 g.; Bouchardat, 0.00005 g. The above values are equiv. to the following wts. of eme-

tine per l. of urine: Tanret, 0.0001 g.; Mayer-Valser, 0.0002 g.; Dragendorff, 0.0004 g.; Bouchardat, 0.0004 g. The orange-yellow color obtained by adding a very small amt. of  $\text{Ca}(\text{ClO})_2$  and about 3 drops  $\text{HCl}$  to the soln. to be tested permitted colorimetric comparison with the control solns.; the sensitiveness of the reaction was approx. 0.0002 g. per 5 cc. of the soln. to be tested or 0.0016 g. per l. of urine. This reaction is not suitable for quant. detn., since the color produced is transitory and the sensitiveness is not sufficiently great. Froehde's reagent, which can only be applied to the dry residue left after evapn. of the filtered  $\text{HCl}$  soln. of emetine, gives a sensitive reaction. The green color produced by addition of 2 drops of the sulfo-molybdic mixt. appeared with the min. concn. of 0.00005 g. emetine- $\text{HCl}$  per 5 cc., this being equiv. to 0.0002 g. per l. of urine. H. S. PAINE.

**Estimation of tryptic action by clarification of turbid emulsions of egg albumin.** P. CARNOT AND H. MAUBAN. *Compt. rend. soc. biol.* 81, 340-2 (1918).—An original soln. is prepd. by beating 1 part of egg white with 3 parts of 1:100 artificial serum and decanting after 24 hrs., a small piece of camphor being added for preservation. When the detn. of tryptic action is to be made 1 cc. of this liquid is dild. with 39 cc. of distd.  $\text{H}_2\text{O}$  and the mixture is heated several mins. at  $90^\circ$ ; a uniform turbidity without any subsequent deposition is produced. Four cc. of the final liquid are placed in each of a series of tubes; to the successive tubes are added an increasing no. of drops (1-10) of the liquid to be tested. The tubes are kept at  $37^\circ$  and the time required for disappearance of turbidity in each instance is noted. In the case of duodenal fluid complete clarification occurred in a few mins. in tubes containing 7-10 drops and in 1-3 hrs. in the tube containing 1 drop. Attempts to use Mett tubes containing ovalbumin for detn. of tryptic action were not satisfactory owing to the formation of a brown coating which covered the end of the cylinder of albumin and prevented further action; the method also lacked sensitiveness. This method was not greatly improved by substituting horse serum for ovalbumin; the increase in rate of attack on the former, as compared with the latter, was not great enough to cause sufficient increase in sensitiveness. Capillary tubes containing muscle exts. (steer, calf, chicken, pig) were also tested; although the sensitiveness was greater than with ovalbumin, at least 1 day was required for sufficient digestion to occur. More sensitive results were obtained with tubes containing 5-10:100 gelatin colored with eosin; considerable action was noted after 12 hrs. contact with duodenal fluid at ordinary temp., even in the case of the least active samples. H. S. PAINE.

**Sources of error in the detection of lactic acid in the stomach contents after a test meal.** P. GÉRARD AND REGNOULT. *Compt. rend. soc. biol.* 81, 388-9 (1918); cf. Pron, *C. A.* 13, 470.—Since the Uffelmann and Berg reactions are not sp. for lactic acid but are also influenced by compds. with primary and secondary alc. groups the glycerol employed for moistening the tube used for withdrawing the stomach contents may constitute an appreciable source of error. A more important source of error is found in the character of the bread used for the test meal. The liquid obtained by macerating 60 g. bread in 250 cc. distd.  $\text{H}_2\text{O}$  for 1 hr. and then filtering gave a positive reaction with both the Uffelmann and Berg reagents. The intensity of the reaction was not modified when the maceration was effected at  $37^\circ$  in the presence of pepsin and  $\text{HCl}$ . The crust and the crumb, when treated separately, gave the same reaction (positive). The filtrate obtained from the above maceration had in general an acidity equiv. to 0.01 N. This acidity was transferred in part to  $\text{Et}_2\text{O}$  when the latter was shaken with the filtrate. The aq. soln. of the residue remaining after evapn. of the  $\text{Et}_2\text{O}$  gave a negative reaction with the Uffelmann and Berg reagents; the original filtrate from the maceration still gave a positive reaction with these reagents after being extd. with  $\text{Et}_2\text{O}$ . When 0.10 g. lactic acid was added to 60 cc. of the filtrate from the bread macera-

tion and this soln. was extd. with  $\text{Et}_2\text{O}$  a sufficient amt. of lactic acid to give a distinctly positive reaction with the above reagents was dissolved by the  $\text{Et}_2\text{O}$ . The positive reaction obtained with the aq. maceration of bread does not appear to be due to lactic acid. This positive reaction was not obtained with all samples of bread. Whenever possible the bread selected for test meals should give no reaction with the Uffelmann and Berg reagents. If such bread is not available the test for lactic acid should only be made after extg. the stomach contents with  $\text{Et}_2\text{O}$ . H. S. PAINE.

**Syphilimetric indexes. Colorimetric determination of the digression from stability.** ARTHUR VERNES. *Compt. rend.* 167, 500-3(1918); cf. *C. A.* 13, 38.—V. makes an artificial scale for the colorimetric measurement of syphilitic infection as follows: 0.1% acid fuchsin, 10 cc.; 1.0% picric acid, 10 cc.; mixt. consisting of glacial  $\text{AcOH}$ , 4 cc., 40%  $\text{HCHO}$ , 2.5 cc.; and water up to 100 cc., 110 cc. This is called "liquid 8" and upon diln. with dil.  $\text{AcOH}$  in the proportions of 1 to 1, 1 to 2, 2 to 7, 4 to 23, 8 to 73, 16 to 227, 32 to 697, and 1 to 65 gives a scale of color running from 7 down to 0, resp. The clinical applications of the above measurements are discussed.

L. W. RIGGS.

**Method of preparing the eosinate of methylene blue and method for staining.** FOSTER A. BECK. U. S. Army. *J. Am. Med. Assoc.* 71, 1651(1918).—"The stain depends upon the formation of methylene azure and methylene violet in the alk.  $\text{MeOH}$  eosin methylene blue soln." The eosinates are dissolved in the  $\text{MeOH}$  and the water-sol. products are pptd. and removed by filtration. The materials and quantities employed, which must be accurately measured, are:  $\text{MeOH}$ , 95 cc.; 0.1 *N*  $\text{NaOH}$ , 5 cc.; water-sol. eosin (yellowish), 0.47 mg.; methylene blue, 0.4 mg. The  $\text{MeOH}$ ,  $\text{NaOH}$  and eosin are mixed in order, as soon as the eosin is dissolved, methylene blue is added and the mixt. shaken 30 min., then filtered and kept in a glass-stoppered bottle. It is ready for immediate use. The advantages are saving of time in the prepn. of the stain and in staining; tap water may be used in place of distd. water; for bacteriologic examns. this stain may be used instead of alk. methylene blue, and it is not necessary to heat to fix the specimen.

L. W. RIGGS.

**Color reaction in typhoid.** E. SILVESTRI. *Riforma medica* 34, 812(1918); *J. Am. Med. Assoc.* 72, 78.—The test is performed by floating 3 cc. filtered urine on a mixt. of 2 cc.  $\text{FeCl}_3$  and 4 or 5 drops pure  $\text{H}_2\text{SO}_4$ . At the zone of contact a brownish yellow tint appears and spreads upward. A ring of turbidity, with greenish reflections, forms on the surface but disappears on agitation, while the brownish yellow tint shows no change even on heating. If albumin or excess urates are present they should be removed before testing. The test is positive in the first days of typhoid or paratyphoid B and, though less pronounced, with paratyphoid A.

L. W. RIGGS.

**Experimental osmosis with a living membrane.** EDWARD KREMER. *Univ. Wis. Science* 48, 599-600(1918).—A dahlia stem in late fall was observed to be filled with water between the nodes. This suggests using a node and internode as an osmotic cell, the node acting as a living semipermeable membrane. Such a cell was improvised by capping the stem with a rubber stopper carrying a glass tube. The cell was filled with salt soln. and placed in water, whereupon the salt soln. rose 6 inches in the tube in less than 1 hr.

L. W. RIGGS.

**Ultrafiltration of small quantities of liquid by centrifugal force.** D. J. DE WAARD. *Arch. Néerl. de physiol.* 2, 530-3; *Chem. Weekblad* 15, 1361(1918).—Instead of high air pressure, the principle of centrifugal force is used in an app. designed for use with blood serums, etc. Ultrafiltration of very small quantities is possible with this app.

JULIAN F. SMITH.

**Ether which colors benzidine, a possible source of error in blood analysis.** F. WREHUIZEN. *Geneesk. Tijdschr. voor Nede. Indië* 58, 201-3; *Chem. Weekblad* 15,

1521(1918).—A warning against using  $\text{Et}_2\text{O}$ , without a control test, in the detection of small quantities of blood. The presence of  $\text{H}_2\text{O}$  is favorable to the formation of the substance in  $\text{Et}_2\text{O}$  which colors benzidine.

JULIAN F. SMITH.

**Volumetric determination of sulfates.** VANSTENBERGHE AND BAUZIL. *Ann. chim. anal.* 23, 210-4(1918).—The method, devised for the examn. of biological fluids is as follows: Treat a known vol. of the fluid with  $1/4$  of its vol. of 15%  $\text{Na}_2\text{CO}_3$  soln., heat to 60-70°, filter, and transfer 30 cc. of the filtrate to a flask. Slightly acidify with  $\text{HCl}$ , heat nearly to boiling, add 20 cc. of  $\text{BaCl}_2$  soln. (12.2 g. per l.), boil not over 1 min., and centrifuge, or filter through talc. To the filtrate add an excess of  $\text{Na}_2\text{CO}_3$ , centrifuge or filter, wash with  $\text{H}_2\text{O}$  until washings are neutral to litmus paper, wash the  $\text{BaCO}_3$  ppt. into a beaker, add 10 drops of 0.1% Me orange soln., and titrate with 0.1  $N$   $\text{HCl}$ . The end point is taken as the tint matching that obtained on adding 10 drops of the indicator and 0.5 cc. of 0.1  $N$   $\text{HCl}$  to an equal vol. of  $\text{H}_2\text{O}$  (0.5 cc. is therefore deducted from the buret reading). **Urine:** Remove the albumin from 100 cc. of the urine, treat at 60-70° with 20 cc. of  $\text{Na}_2\text{CO}_3$  soln., and filter. To det.  $\text{SO}_4^{--}$ , acidify 30 cc. of the filtrate with  $\text{HCl}$  and proceed as above outlined. Oxidized S is detd. in another 30 cc. of the filtrate after hydrolyzing the sulfo-ethers by boiling 15 min. with 3 cc. of  $\text{HCl}$  and 50 cc. of  $\text{H}_2\text{O}$ . Total S is detd. in 30 cc. of the filtrate after destruction of the org. matter by boiling (until decolorized) with 3 cc. of  $\text{KClO}_3$  soln. (0.3 g. in 25 cc.  $\text{H}_2\text{O}$ ). **Serum:** Dil. 10 cc. of serum with 40 cc. of 10%  $\text{NH}_4\text{Cl}$  soln., add a few drops of  $\text{AcOH}$ , heat to boiling to coagulate the albumin; filter through  $\text{Na}_2\text{CO}_3$ , wash the filter, evap. the filtrate to 10 cc., acidify with  $\text{HCl}$ , and continue as above, adding 5 cc. of the  $\text{BaCl}_2$  soln. **Blood:** Calcine 10 or 20 cc. of blood in a crucible with a mixt. of equal parts of  $\text{Na}_2\text{CO}_3$  and  $\text{KNO}_3$ , take up with  $\text{H}_2\text{O}$ , evap. to dryness, dissolve the residue in  $\text{HCl}$  and continue as with serum.

F. W. SMITHER.

**Analyses of blood gases. I. Qualitative and quantitative detection of acids in small quantities of blood by estimation and distribution equilibria.** H. STRAUB AND KLOTHILDE MEIER. *Biochem. Z.* 89, 156-77(1918); *J. Chem. Soc.* 114, II, 467-8.—The laws of mass action regulate the relationship between (a) the undissociated, (b) the dissociated parts of the electrolytes of the blood, and (c) the H-ion concn. If 2 of these are known, the 3rd can be calcd. A method is described for detg. whether acids stronger or near the strength of  $\text{CO}_2$  are present, which depends upon the soly. of  $\text{CO}_2$  in blood or serum. It consists in the detn. of the equilibria of distribution between  $\text{CO}_2$  and the non-volatile acids of the blood. The detn. of the abs. soly. of  $\text{CO}_2$  at a given partial pressure of the gas, or at a given H-ion concn., gives a means of estg. the amt. of pathological acids present in the blood. Various examples of the use of the method are given.

C. J. WEST.

**Volumetric estimation of histidine and other glyoxaline derivatives.** C. L. LAUTENSCHLAGER. *Z. physiol. Chem.* 102, 226-43(1918); *J. Chem. Soc.* 114, II, 466.—Histidine can be estd. by treating its soln. with an excess of diazobenzenesulfonic acid, boiling with alc. to destroy the excess of acid and then titrating the stable histidine dye with  $\text{TiCl}_3$  by Knecht and Hibbert's method. An alternative method consists in adding standard  $\text{AgNO}_3$  to the histidine soln. until a drop no longer gives a red coloration with an alk. soln. of diazobenzenesulfonic acid. As only the free base reacts with the acid to form a red dye, while the Ag salt gives no color reaction, the end-point is revealed by the non-appearance of the red color. For its detn. in protein, the histidine must 1st be sepd. from the other products of hydrolysis, especially tyrosine; this can be effected by means of Ag lactate or  $\text{HgCl}_2$ , which forms insol. compds. with histidine.

C. J. WEST.

**Estimation of the purin bases in nucleic acids after cleavage without the production of humin.** R. FEULGEN. *Z. physiol. Chem.* 102, 244-51(1918); *J. Chem.*

Soc. 114, II, 464.—The nucleic acid is heated with a soln. of  $\text{NaHSO}_4$  at  $160^\circ$  under pressure, whereby a colorless, humin-free hydrolysate is obtained. On cooling, the guanine seps. quant., while the adenine in the filtrate is pptd. as phosphotungstate, then converted into the  $\text{Ag}_2\text{SO}_4$  compd. and finally weighed as the picrate.

C. J. WEST.

Estimation of the residual nitrogen in blood serum. FISCHER. *Z. physiol. Chem.* 102, 266–74(1918); *J. Chem. Soc.* 114, II, 452.—In the detn. of the residual N in blood serum, it is essential that the proteins should be so completely removed by pptn. that no trace of the latter can be detected in the filtrate. This result can be achieved by pptg. with  $\text{AcONa}$  or  $\text{NaCl}$  in the presence of  $\text{AcOH}$  at  $100^\circ$ , or by treatment with uranium acetate at the ordinary temp. F. recommends the latter method, which yields values for the residual N varying from 20 to 90 mg. of N per 100 cc. of blood serum.

C. J. WEST.

Mistletoe (BONNAMOUR, NIQUET) 17. An iodine-tannin reagent (TSAKALOTOS, DALMAS) 7. Determination of dextrose with hypiodite (WILLSTÄTTER, SCHUDEL) 7.

### C. BACTERIOLOGY.

The bactericidal action of whole blood with a new technic for its determination. G. O. HEIST, S. SOLIS-COHEN AND M. SOLIS-COHEN. *J. Immunology* 3, 261–75(1918).—The serum of a pigeon does not differ in its action upon pneumococci from the serum of the mouse or the rabbit. If small numbers of living pneumococci are seeded by a suitable method in pigeon's blood before it coagulates, the pneumococci fail to multiply. On the contrary, if pneumococci are seeded in mouse or rabbit blood before it coagulates, they grow with great vigor. Fresh defibrinated blood of both immune and susceptible species is an excellent culture medium for the pneumococcus. This organism fails to multiply in the blood of a rabbit which has been suitably inoculated with killed pneumococci, the reaction being sp. to type. The blood of a man who has recovered from lobar pneumonia prevents the development of pneumococci belonging to the type causing his disease.

GEO. T. CALDWELL.

Methods of isolation and identification of the members of the colon-typhoid group of bacteria. Late fermentation of lactose. J. BRONFENBRENNER AND C. R. DAVIS Harvard Univ. *J. Med. Res.* 39, 33–7(1918).—An increase of lactose concn. above 1% in liquid media may greatly hasten the identification of organisms which ferment lactose slowly, after isolation from the plate.

GEO. T. CALDWELL.

Identification of tubercle bacilli using alcoholic alkali solutions as decolorizer. LOUIS BOURDY. Grenoble. *Bull. sci. pharmacol.* 25, Pt. 2, 296–8(1918).—A rapid, simple technic involving fixation and staining as usual with Ziehl's soln., washing with  $\text{H}_2\text{O}$  and decolorizing 3–5 min. in a soln. of 10 cc. officinal aq.  $\text{NH}_3$  and 90 cc. 96° alc., restaining preferably with Gabbet's soln. (2 g. methylene blue to 100 cc.  $\text{H}_2\text{SO}_4$  (1:4)) for several seconds, washing with  $\text{H}_2\text{O}$ , and drying. Excellent results are claimed with difficult sputa, urinary sediments, milk, butter, and feces.

M. H.

New culture medium for general use in human microparasitology. DOMENICO CROZZI. Firenze. *Sperimentale* 72, 291–308(1918).—Media hitherto employed for general use have been deficient owing to their prepn. from the flesh of animals, have been poor in free amino acids, free from vitamins, of unsuitable  $\text{H}^+$  concn., or have contained insufficient mineral salts or carbohydrates. The use of the human placenta is recommended as a material furnishing the necessary elements and one accessible without difficulty. The fresh placentas are thoroughly washed, comminuted with a meat chopper, weighed, placed in a flask with 2 parts by weight of Ringer-Locke soln., and treated with 1% of the total weight of pancreatin and 0.5%  $\text{CHCl}_3$ , after making sure that the alkalinity is the same as that of human blood (alk. to litmus but not to phenol-

phthalein). Generally after 24 hrs. digestion at 40-2° the biuret reaction is very weak and the tryptophan reaction very strong, and the mixt. is then filtered, first through cloth, then through paper, and the alkalinity is again tested as above and corrected if necessary. For use as broth the yellow liquid is steamed 1 hr., filtered again, the alkalinity again controlled, and 0.5% glucose and 2% glycerol added, followed by sterilization. Agar and gelatin media are prepared from the liquid in the usual way. 3 drops of unheated human blood are added to each tube immediately before use in order to supply vitamins; after the 1st transplantation and in the case of the more resistant microorganisms this addition is unnecessary. Good results are claimed with anaerobes as well as aerobes, rapid growth, long life, and late development of degenerative forms being obtained even with the bacteria ordinarily considered difficult to cultivate.

M. HEIDELBERGER.

**Action of fruit juices upon the typhoid bacillus.** R. KO. *Taiwan Igakukai Zasshi* 179, 569-80(1917); *Jap. Med. Literature* 3, 73(1918).—Most fruit juices, which are acid, exert a bactericidal action on *B. typhosus*; juice of half-ripe fruit usually is more efficient than that from fully ripe fruit. "Tannic acid is the strongest of the vegetable acids, followed by citric and tartaric and finally by malic. Sugars and starches have no antiseptic action no matter how strong." "Lemonades" prepd. from the acids have considerable bactericidal action, most marked in those containing HCl, less marked with tartaric acid or H<sub>2</sub>SO<sub>4</sub>, and least marked with citric acid. Fruits whose juices do not favor the viability of *B. typhosus*, are: *Ananas sativus*, *Pisidium gayana*, *Eugenia javanica*, *Diospyros kaki* (persimmon), *Musa sapientum*, *Nephelium litchii* (litchii nut), *Vitis vinifera* (grape), *Prunus persica* (peach), *Prunus communis*, *Citrus decumana*, *Myrica rubra*, *Averrhoa carambola*. Fruits whose juices do not kill *B. typhosus*, are: *Nephelium longana* (longan fruit), *Citrus nobilis* (navel orange), *Eryobotrya japonica* (Biwa), *Mangifera indica* (mango), *Citrullus vulgaris* (watermelon), *Eigen cariae*, *Pyrus sinensis* (pear).

JULIAN H. LEWIS.

**Consideration of methods for demonstrating tubercle bacilli in the urine.** ERNEST M. WATSON. *Am. J. Med. Sci.* 156, 636-43(1918).—The methods of Walker, Uhlenhuth, Ellerman and Erlandsen, Lange and Nitsche, Kozlow, Petroff and that of Crabtree are given briefly. The present method herein described involves centrifuging urine collected from a patient who has had the intermittent organ washed, previously, with sterile water and the ureter irrigated. Antiformin is used where there is much sedimentation. Smears are made from the sediment stained with carbo-fuchsin, decolorized in HCl (2%) and counterstained with Löffler. A guinea-pig test may be positive when the above method is negative.

W. MORSE.

**Effect of heat on the spores of *Bacillus botulinus*.** GEORGINA SPOONER BURKE. Stanford Univ. *J. Am. Med. Assoc.* 72, 88-92(1919); cf. Dickson and G. E. Burke, *C. A.* 12, 2087.—Ten strains of *B. botulinus* were studied. The technic is given in detail and the results assembled in five tables. The most important conclusions are as follows: Free spores of *B. botulinus* grown in either broth or brain cultures are highly resistant to heat, those from brain cultures being the more resistant. A temp. of 100° or more inhibits the development of the spores so that the incubation period is very much increased. None of the household methods of canning will kill the spores of the more resistant strains of *B. botulinus*. Fractional sterilization on three successive days is of doubtful value because the first exposure to 100° for 15 min. retards the germination of the spores so that they do not develop before the third sterilization period.

Canning under pressure at prolonged periods may render the food sterile, but a pressure of 15 pounds for 10 min. does not kill the more resistant spores. The source of *B. botulinus* is not at present known, but it is quite certain that it is not under the skin of perfectly sound fruit and vegetables that are not over-ripe. Such fruit and vegetables should be washed before peeling and every detail of cleanliness, including the elimination of flies, be observed throughout the process. The contents of the jar must not be tasted "to see if it is spoiled," as the smallest taste is fatal if the toxin is strong. Canned food should be condemned if there are bubbles inside the jar and gas or liquid escapes as the top is unscrewed; if the odor somewhat resembles that of rancid cheese; or if the solid portions have a mushy disintegrated appearance. The toxin of *B. botulinus* may be entirely destroyed by boiling five min. although the spores are not killed by this treatment. It is the toxin and not the spores that produces illness, for the bacilli do not produce toxin when taken into the body. Since *B. botulinus* produces toxin only in material that has been sealed in an air-tight container for a week or more, there is no danger of botulism from uncooked or freshly cooked fruit or vegetables.

I. W. RIGGS.

Theory and practice of disinfection by alcohol. JOHANNE CHRISTIANSEN. *Z. physiol. Chem.* 102, 275-305 (1918); *J. Chem. Soc.* 114, I, 564; cf. *C. A.* 12, 1990.—The disinfecting power of alc. depends not only on its ability to ppt. the proteins of bacteria but on its capacity to penetrate the cell walls, and thus exert its action on the protoplasm of the bacteria. The latter quality is dependent on the surface tension of the alc. Propyl alc. seems to be the most suitable of all the alcs. for direct application to the skin as a means of disinfection prior to surgical operation. Its toxicity is considerably greater than that of EtOH, and on account of its dissolving power over fats, it is able to enter readily the pores of the skin.

C. J. WEST.

#### D. BOTANY.

CARL L. ALSBERG.

Immunity of plants against compounds which they produce. RAOUL COMBES. *Compt. rend.* 167, 275-8 (1918).—A study of the effect of the glucoside agrostemma-saponin upon rose-campion (*Agrostemma githago*), peas (*Pisum sativum*), buckwheat (*Polygonum fagopyrum*), and radishes (*Raphanus sativus*). Knop's soln. alone was used, and also with 0.10, 0.25, 0.50, 1.0, 2.0 and 10 parts per 1000 of the saponin added. Injurious effects were noted on the last 3 named plants even in the dil. concns., while even the concd. solns. produced no ill effects upon *Agrostemma githago*. It is noteworthy that this last-mentioned plant produces the glucoside under study, and that it is not produced by the other three. C. concludes that it is not advisable from the standpoint of plant physiology to study the effects of sp. compds. upon plants not producing them and draw conclusions therefrom as to the part they play in the tissues of species which, in nature, do produce them.

R. B. DEEMER.

Chemical changes accompanying abscission in *Coleus blumei*. HOMER C. SAMPSON. *Bot. Gas.* 66, 32-53 (1918).—Abscission of leaves in *Coleus blumei* is the result of the conversion of cellulose into pectose, and this is further changed into pectin and pectic acid. The amt. of pectic acid formed is in excess over that of the available calcium sufficient to maintain the solidity of the middle lamella of the cell walls of the abscission layer. These processes are perhaps initiated and probably accelerated by the presence of oxidases and ferric ions, both of which accumulate in the abscission layer.

B. HARROW.

Contributions to the knowledge of the carbohydrates of vegetables. ERNST BUSOLT. *J. Landw.* 64, 357 (1916); *Biedermanns Zentr.* 47, 287 (1918).—B. had previously sepd. mannitol from aq. exts. of asparagus, green French beans and cauliflower and mannitol and dextrose from savoy. In this investigation he obtained mannitol

and dextrose from *carrots* in a similar manner. Besides proving mannitol and dextrose present in aq. exts. of green *peas* the presence of fructose and glucuronic acid was shown.

##### NORMAL.

The constancy of the protein quotient during intensive digestion and prolonged starvation. S. HANSON. *J. Immunology* 3, 67-74(1918).—The object of the expts. performed was to det. the influence on the protein quotient of a disturbance or metabolism produced by periods of digestion alternating with prolonged periods of starvation, using rabbits as the exptl. animal. The quotient was found to remain normal during the digestion periods.

GEO. T. CALDWELL.

The relative content of antiscorbutic principle in limes and lemons. HARRIETTE CHICK, E. MARGARET HUME AND RUTH F. SKELTON. *Lancet* 1918, II, 735-8.—The antiscorbutic value of the juice of fresh limes is distinctly inferior to that of fresh lemons. The former has a potency of about  $\frac{1}{4}$  that of the latter. Preserved lime juice was found useless for the prevention of scurvy in young monkeys.

GEO. T. CALDWELL.

The influence of diet on teeth formation. MAY MELLANBY. Univ. London. *Lancet* 1918, II, 767-70.—A diet containing in abundance those articles with which the fat-soluble A accessory food factor is associated, *e. g.*, cod liver oil, butter, allows the development in puppies of sound teeth. A diet otherwise adequate but deficient in these substances brings about the following defects in puppies' teeth: (a) delayed loss of the deciduous teeth, (b) delayed eruption of the permanent teeth, (c) irregularity in position and overlapping, especially of the incisors, (d) partial absence of or very deficient enamel, (e) low Ca content of the teeth. These results cannot be considered as being due to acute illness or "malnutrition," for the improvement of the teeth by the addition of substances containing fat-soluble A is as characteristic as the deleterious effect of a deficient diet. There is evidence that the defective teeth are most pronounced in the rapidly growing puppies.

GEO. T. CALDWELL.

The antiscorbutic value of the raw juices of root vegetables with a view to their adoption as an adjunct to the dietary of infants. HARRIETTE CHICK AND MABEL RHODES. *Lancet* 1918, II, 774-5.—Cow milk preserves distinct antiscorbutic properties, but these are present in small degree in comparison with other antiscorbutic food-stuffs. Its value in this respect is further reduced after heating or drying. Various materials that might suitably be included in an infant's diet were tested exptly. on guinea pigs. Among fresh fruit juices that of the orange is easily the most suitable and possesses a value about 10 times as great as that of fresh grapes. Of the raw vegetable juices examd., raw swede juice is far the most potent, approxg. in value to raw orange juice. The raw juice of carrots is much inferior, and that of beet roots fails to prevent scurvy in the largest dose (20 cc.) that can be administered to the exptl. animals.

GEO. T. CALDWELL.

The value of germinated beans in the treatment of scurvy. H. W. WILTSHIRE. *Lancet* 1918, II, 811-3.—Germinated beans were found quite as potent as raw lemon juice in the treatment of scurvy. In cooking vegetables the destruction of the vitamins cannot be ascribed to the production of alkalinity.

GEO. T. CALDWELL.

Relative morbidity of breast and bottle-fed infants. H. M. McCLANAHAN. Omaha, Neb. *Arch. Pediatrics* 35, 652-60(1918).—Breast milk contains natural anti-

bodies, and thereby renders the infant fed less susceptible to infections (except influenza and tuberculosis), increases the resistance if infection occurs, and decreases the morbidity. Breast milk is digested by the infant more rapidly and with less work by the digestive organs than is modified cow milk. Hence breast milk is superior to cow milk as an infant food.

JOSEPH S. HEPBURN.

**Somatose.** WILLIAM THOMSON. *Mem. and Proc. Manchester Lit. Philos. Soc.* 62, Part 1, Memoir 5, 14 pp. (1918).—Somatose, an invalid food, is prepd. from the residue obtained on extn. of meat with hot water. The residue is heated with water for some time at a pressure of 90 lbs. to the sq. in. (320° F.), and dissolves to a large extent. The soln. is filtered, evapd. to dryness, and powdered. The brownish product is somatose; it contains 13.13% N. Tame mice were the exptl. animals. They gained wt. on rations of (1) oats and water, (2) oats, lean meat, and water, and (3) oats, plasmon (casein), glucose, and water, and lost wt. on rations of (4) oats, somatose, glucose, and water, (5) oats, port wine residue (total solids), and water, and (6) oats, water, and residue from port wine which had contained somatose in soln. The loss in wt. was greater on ration (6) than on ration (5) during a feeding period of 19 days. Mice fed ration (4) minus somatose remained at or above their initial body wt. The conclusion is reached that somatose is neither a food nor a neutral body, but an irritant producing gastric disturbance and diarrhea. Expts. are also reported in which mice were fed a diet of oats, water, and a species of raw starch. After ingestion of either potato- or sago-starch, large quantities of intact starch granules, and some slightly digested, were excreted in the feces which had a white color. When the ration contained either maize- or tapioca-starch, a small quantity of intact starch granules was present in the feces. Apparently both rice- and wheat-starch were completely digested by the mice.

JOSEPH S. HEPBURN.

**Food requirements of the Japanese people as indicated by prison dietsaries.** R. INABA AND T. UYENO. *Tokyo Igakukai Zasshi* 31, No. 20, 3-20 (1917); *Jap. Med. Literature* 3, 75-6 (1918).—A prisoner at full labor received a daily grain ration of 4.2 go of rice and 1.8 go of barley; 1 go = 180 cc. This was supplemented with vegetables as soups or boiled mixts., with sea weed, pumpkin, potatoes, bean curd, and fish occasionally; meat was not given. The ration had the following daily value; figures in parentheses represent the amt. utilized: N 17.31 g. (12.59 g.), protein 108.21 g. (78.59 g.), fat 34.67 g. (28.50 g.), carbohydrate 556.97 g. (552.05 g.), cal. 3050 (2850). Expts. were made to ascertain the exact diet required for maintenance of wt. under these conditions, the only variable being the amt. of rice and barley in the ration. Seven prisoners were studied separately. The max. and minimum values obtained during maintenance of wt. and a positive N balance included 76.07 and 108.21 g. protein daily, 29.5 and 43.7 cal. per kg. of body wt. daily.

JOSEPH S. HEPBURN.

**Nitrogen partition in the urine of dogs fed on different substances and subjected to strenuous exercise at high temperatures.** N. GORO. *Tokyo Igakukai Zasshi* 32, No. 4, 51-8 (1918); *Jap. Med. Literature* 3, 78 (1918).—A diet of Kara (the refuse from beans in the manuf. of Tofu or bean curd) increased the  $\text{NH}_3$  of the urine to 10 to 20 times the normal amt., and decreased the urea, but produced no change in the total N of the urine; it caused the excretion of acetone and diacetic acid in considerable amt. A diet of egg white increased the amino acid N to approx. 6 times its normal value, made no change in the  $\text{NH}_3$ , and caused a slight reaction for acetone and diacetic acid in the urine. Sugar produced an increase in body temp. and in amino acid N,  $\text{NH}_3$ , uric acid (to 3 times normal), and purine bases (to approx. 8 times normal); during rest at room temp., the urea gradually returned to its normal value.

JOSEPH S. HEPBURN.

**Influence of fats upon the toxicity of food proteins; their role in the utilization of nitrogenous materials. Therapeutic applications.** F. MAIGNON. *Compt. rend.* 167,

281-3(1918).—The conclusions of the previous recent papers (cf. *C. A.* 12, 2001-2) are restated. In support of these exptl. results the evidence of clinical observation is added, which confirms the hypothesis of the intervention of fats in the metabolism of nitrogenous foods. Among such observations may be mentioned cod-liver oil in cases of tuberculosis and of those affections accompanied by N denutrition; also the substitution of fats for carbohydrates in diabetes. L. W. RIGGS.

**Soldier's ration and physiology.** F. RHO. *Riforma medica* 34, 561(1918); *J. Am. Med. Assoc.* 71, 1256.—A reply to Bottazzi's arguments (cf. *C. A.* 12, 2603) and a discussion of the physiologic bases of a well balanced diet. On the smaller vessels there is often no settled ration and the men eat to suit their taste. Under these conditions it was found that they did not take over 2800 cal. and were satisfied with 90 to 96 g. of protein. The soldiers and sailors in general have gained from 3 to 5 kg. in wt. since the war opened. The present ration allows some liberty of choice, and consists of 130.5 g. protein. 45 of fats and 535.5 carbohydrates. This provides 3149 gross cal., or including the wine ration 4329 cal. The more vegetable and fruit diet of the Italians in peace times should not be regarded as a token of inferiority but the reverse. Quoting Alfieri, "The plant man thrives better in Italy than elsewhere." L. W. RIGGS.

**Some nutritive properties of corn.** J. S. HUGHES. *Kansas Agr. Expt. Sta., Tech. Bull.* 5, 39(1918).—Expts. were conducted on the feeding of corn to pigeons, squirrels and chickens. Corn is shown to contain relatively large quantities of anti-neuritic substances, similar to those found in rice polishings. The corn germ did not prevent polyneuritis. J. J. SKINNER.

**Is vitamine identical with secretin?** B. C. P. JANSEN. *Geneesk. Tijdschr. voor Ned. Indië* 58, 191-7; *Chem. Weekblad* 15, 1520-1(1918).—Various statements occur in the literature about the identity of secretin with vitamine. Expts. showed that the vitamine from rice hulls is not identical with secretin. If it were, the fact could be used as the basis for a quant. method of detg. vitamine. An incidental result of the expts. was the observation that *K salts injected into the blood vessels are poisonous.*

JULIAN F. SMITH.

#### ABNORMAL.

**Action of beri-beri serum upon the heart of the frog.** G. KANEKO. *Chugai Iji Shimpo* 895, 807-11(1917); *Jap. Med. Literature* 3, 56(1918).—The serum and milk of nursing beri-beri patients usually, though not invariably, contain a toxin which contracts the heart of a frog. JOSEPH S. HEPBURN.

**Examination of the cerebrospinal fluid in beri-beri.** H. IIDA. *Chugai Iji Shimpo* 895, 812-5(1917); *Jap. Med. Literature* 3, 56(1918).—In certain cases of beri-beri the pressure of the cerebrospinal fluid was greatly increased, especially during the acute stage; the pressure was as low as 100 mm. in slight cases, and as high as 180 to 280 mm. in certain cases; the blood pressure remained low. Cerebrospinal fluid, which exerted a high pressure, was drawn from the patient and was perfused through a rabbit ear; it was found to possess a powerful vasoconstrictor action. JOS. S. HEPBURN.

**Diet in hypertension.** GEORGE CARROLL SMITH. *J. Am. Inst. Homeopathy* 11, 645-54(1918).—A discussion of the diet in cases of high blood pressure of the benign or presclerotic type, the cardioarterial type, and the type due to interstitial nephritis. Attention is paid to the relation between carbohydrate, fat, and protein in the ration, its content of Fe and of acid-forming and base-forming elements. JOS. S. HEPBURN.

**Metabolism in a case of hemochromatosis.** C. W. McCLURE. *Boston. Arch. Intern. Med.* 22, 610-16(1918).—There was a retention of iron. The respiratory quotient and basal metabolism were normal. There was no gross disturbance in the intermediary metabolism. F. HULTON-FRANKEL.

The excretion of creatine, creatinine and uric acid in acute febrile conditions. C. W. McCLURE. Bethlehem, Pa. *Arch. Intern. Med.* 22, 719-49(1918).—The end products of protein metabolism, creatine, creatinine and uric acid, were studied on patients suffering from typhoid fever who were on a "Schaffer-Coleman" diet at the time of the expt. This diet is rich in fat and carbohydrate. The finding showed that there is no const. relation between the presence of pyrexia and creatinuria. Creatinuria, while usually occurring coincidentally with loss in body wt., is not definitely related to either the rapidity or the amt. of wt. loss. During the period of pyrexia creatinuria may occur unaccompanied by disturbances in the excretion of uric acid, and of creatinine. An increase in the output of creatinine is not always related to a loss in body wt. An increase in the output of uric acid during the course of an infectious disease is not wholly dependent on the presence of pyrexia. No definite relationship is found between the severity of the symptoms manifested by the patients and the amts. of creatine, creatinine and uric acid found in the urine. The disturbances in the excretion of creatine, creatinine and uric acid in fever are expressions of the effects of toxins in metabolism, and these continue during the period of convalescence. The loss of uric acid, creatine and creatinine is retarded by high-caloric diets rich in carbohydrates.

F. HULTON-FRANKEL.

The comparative food value of protein, fats and alcohol in diabetes mellitus, as measured by nitrogen equilibrium. HERMAN O. MOSENTHAL AND GEORGE A. HARROP. Baltimore. *Arch. Intern. Med.* 22, 750-758(1918).—The aim of the investigation was to det. the comparative values of protein, fats and EtOH as N spacers when added to a carbohydrate-free diet, in diabetes mellitus. The patients were given diets of a const. protein, fat and starch content, and of such caloric value that there was a negative N balance. This was the control period. Different amts. of protein, fat and EtOH were added to the diet and effects on the N balance studied. The results showed that the addition of an equal number of calories of protein, fat or EtOH to a low caloric carbohydrate-free diet, results in the assimilation of considerable amts. of N when the protein is used, a favorable N balance in only occasional instances with fat, and no change in N equil. with EtOH. This would point to a high-protein diet as the most advisable low-calorie diet, free of carbohydrate, by which to conserve the body tissues and furnish a maintenance ration for diabetics.

F. HULTON-FRANKEL.

Content of ketone and ketogenic products in the urine of patients with traumatic shock. RENÉ FABRE AND RENÉ CLOGNE. *Compt. rend. soc. biol.* 81, 884-6(1918).—"Ketone substances" (preformed  $\text{Me}_2\text{CO}$  and acetoacetic acid) were detd. by acidifying urine with  $\text{H}_2\text{SO}_4$  and distg.; "ketogenic substances" ( $\beta$ -hydroxybutyric acid, etc.) were detd. by treating the residue from the 1st distn. with  $\text{K}_2\text{Cr}_2\text{O}_7$  and again distg.  $\text{Me}_2\text{CO}$  in both cases was detd. by producing  $\text{CHI}_3$  in the alk. distillates by addition of a 0.1 N I soln. and titrating the excess of I with  $\text{Na}_2\text{S}_2\text{O}_3$  soln. The contents of  $\text{Me}_2\text{CO}$  from "ketone" and "ketogenic" substances in the urine of normal individuals was 0.003-0.005 g. and 0.011-0.018 g. per l., resp. These contents were only slightly greater with slightly fatigued patients (soldiers) than with normal individuals. The contents of  $\text{Me}_2\text{CO}$  from "ketone" and "ketogenic" substances in the case of patients with traumatic shock were 0.021-0.044 g. and 0.044-0.175 g. per l., resp.; in the case of patients with gaseous gangrene these contents were 0.015-0.039 g. and 0.054-0.125 g. per l., resp. These values cannot be attributed to fatigue, fast or effect of anesthesia, since seriously wounded patients under the same conditions showed practically normal values.

H. S. PAINE.

Metabolism of the organism in a state of shock and observations on the peculiar sensitiveness of shocked subjects to anesthetics. W. MESTREZAT. *Compt. rend. soc. biol.* 81, 888-91(1918).—The peculiar sensitiveness of shocked subjects to anes-

thetics was shown by a remarkable rise in the formol index curve ( $\text{NH}_3$  + amino acids expressed as  $\text{NH}_3$ ) when anesthetics were administered. Metabolism was greatly disturbed by shock, this being shown by the abundant presence in the urine of N, C and H compds. which are not normally present or which are present in much smaller proportions. The ratio to urea of residue at  $100^\circ$ —(ash + urea) was much greater than the physiol. value. The coeff. of acidosis was considerably greater than normal.

H. S. PAINE.

**Intoxication from war wounds; nitrogen retention by the wounded.** P. DUVAL AND A. GRIGAUT. *Compt. rend. soc. biol.* 81, 873-81(1918).—Observations of wounded soldiers showed an increase in non-protein N compds. and residual N of the blood which was parallel to a decrease in the non-protein N of the traumatized tissue; this increase was proportional to the intensity of the phenomena of intoxication. The av. normal values for content of total non-protein N in the plasma, whole blood and corpuscles were 23, 32 and 48 cg. per 1000 g., resp. The av. normal values for content of residual N (subtracting the urea N content from the above) in the plasma, whole blood and corpuscles were 10, 20 and 32 cg. per 1000 g. Both total non-protein and residual N were, as a rule, increased (not greatly in most cases) in the wounded. This increase commenced immediately after the wounding, passed through a max. on the 2nd day and decreased progressively to normal with convalescence. Regardless of the intensity of additional causative factors such as infection, jaundice and anesthesia the increase in non-protein N of the blood rarely resulted, in most cases, in values reaching twice the normal. On the contrary, values greater than twice the normal were usually encountered in the plasma of wounded in a state of shock. This increase affected the corpuscles as well as the plasma. The latter was first affected, however, and the changes in its non-protein N curve always preceded those of the similar curve for the corpuscles. In cases of recovery the total non-protein and residual N decreased progressively to normal; in case of death the increase was const. and regular until death ensued. In 1 instance the blood 5 hrs. before death contained 0.673 g. residual N and 0.347 g. urea N per 1000 g. This increase in the non-protein N of the blood during shock resembles the azotemia of Bright's disease with the exception that the latter is a case of retention of urea, while N retention during shock is a case of retention of residual N. In the case of shock the residual N value varied practically proportionally to N retention. While increase in residual N is due to alteration in the hepatic cells, hepatic insufficiency is not the primary cause. Retention is primarily due to the influence of the sudden afflux to the liver of the N reserve of the tissues which is liberated by the traumatism. W. Mestrezat, commenting on the above, directed attention to the relation during shock of an unusually high content of undetd. N in the urine (cf. preceding abstr.) and the increase in residual N in the plasma as indicated above.

H. S. PAINE.

#### F. PHYSIOLOGY.

ANDREW HUNTER.

**The pigmentation of nerve cells. I. The non-fatty melanotic pigment in the dog and rabbit produced by chronic depression.** D. H. DOLLEY AND FRANCES V. GUTHRIE. Univ. Missouri. *J. Med. Res.* 39, 123-42(1918).—Pigment is not a natural constituent of the cells of any region of the central nervous system or of the Gasserian, spinal, vagus and superior cervical ganglia of the rabbit and dog. A melanotic pigment is produced by functional depression of some duration in any or all cells in these animals. Under no conditions does a fat-holding pigment occur in these cells. GEO. T. CALDWELL.

**Action of chicken serum upon the blood-vessels.** M. TOTO. *Chugai Iji Shimpō* 897, 947(1917); *Jap. Med. Literature* 3, 57(1918).—Blood serum from normal chickens was dild. with Ringer soln. and injected into the leg of a frog; it caused a

pronounced contraction; the degree of contraction was in direct proportion to the concn. of the serum. This vasoconstricting property was not destroyed by heating the serum at 60° for 1 hr., but was weakened or removed by keeping the serum in an ice-box for 1 to 2 days. Vasoconstriction was not produced when the serum was applied directly to the exposed mesentery of a frog or rabbit. Serum from chickens, which were affected with rice disease—a form of beri-beri—produced vasoconstriction even more decidedly than did that from normal birds.

JOSEPH S. HEPBURN.

Oxygen capacity of blood combined with lung extract. A contribution to the study of the gas exchange in the lung. M. HASHGAWA. *Tokyo Igakukai Zasshi* 31, No. 12, 1-12(1917); *Jap. Med. Literature* 3, 59(1918).—Lung tissue was thoroughly cleansed, then extd. with Ringer soln. Blood was treated with CO<sub>2</sub> and with H, then mixed with the ext. The mixt. was enclosed in a separatory funnel for 30 min., and the O content of the blood then detd. For a control, the same blood was mixed with Ringer soln. The exptl. blood proper never contained more O than the control. Therefore participation of an enzyme in the mechanism of the gas exchange in the lung is apparently excluded.

JOSEPH S. HEPBURN.

Power of the lens of the eye to neutralize alkaline solutions. R. HAYANO. *Tokyo Igakukai Zasshi* 31, No. 21, 1-35(1917); *Jap. Med. Literature* 3, 60(1918).—In the eye of normal animals, including cattle, dog, guinea pig, goat, cat, and man, the lens possesses the power to neutralize alk. solns. The power depends on the size of the lens, is not specific for any animal, is less in old animals than in young ones, and has disappeared in eyes that have been removed for a considerable period of time, or have been taken from dead bodies. A soln. prepd. from the lens has this property; a concd. emulsion of the lens combines with relatively more alkali than is neutralized by a more dil. emulsion of the same amt. of lens. The more concd. the alkali soln., the greater is the amt. of lens substances with which it combines. Higher temps. apparently decrease the combining power; however, the power is not readily lost by a soln. kept at a const. temp. The peripheral portion of the lens is more anti-alk. than the central portion. The neutralizing power is below normal in a lens affected by cataract. The power to neutralize alkali is ascribed to Krystallin A and B, and not to the albumin and albuminoids of the capsule.

JOSEPH S. HEPBURN.

Heat hemolysis and its relation to blood serum. Y. KUNO. *Tokyo Igakukai Zasshi* 32, No. 2, 1-36(1918); *Jap. Med. Literature* 3, 77(1918).—Mixts. of serum and a suspension of erythrocytes were kept at various temps., and the time at which hemolysis occurred was compared with a control. The power to inhibit hemolysis was greater in fresh serum than in older samples. Inhibition was obtained with serum diluted 1:20,000 and reached its max. with serum diluted 1:50. No difference was observed between homologous and heterologous series, even when the species were far apart. The inhibitory power was completely destroyed by inactivation of the serum for 30 min. at 50°.

JOSEPH S. HEPBURN.

Remarks on the concentration of urea in normal blood. LUDWIG KAST AND EDNA L. WARDELL. New York. *Arch. Intern. Med.* 22, 581-92(1918).—Of 244 cases studied 84%, with not more than 20 mg. of urea N per 100 cc., showed no symptoms of kidney lesion or very slight symptoms. Those individuals with more than 20 mg. showed symptoms of renal function impairment. It is concluded that 20 mg. of urea N per 100 cc. of blood may safely be taken as the upper limit for the normal and that the detn. of urea N is a safe index of renal function.

F. HULTON-FRANKEL.

The effect of thymus gland injections on the growth and behavior of guinea pigs. D. M. OLKON. Chicago. *Arch. Intern. Med.* 22, 815-29(1918).—The injection of thymus gland intraperitoneally into male guinea pigs caused a reduction in wt. There

were muscular spasms, dyspnea and convulsions, spasms being greater than those caused by the injection of muscle or NaCl. Large doses killed some of the animals. The appearance of the animals was that of grave metabolic disturbances, emaciation, dryness and roughness of hair. F. HULTON-FRANKEL.

**Studies in the functional estimation of stomach contents. III. Effects of hydrochloric acid therapy on the acid titer of the stomach during digestion.** BURRILL B. CROHN. *Am. J. Med. Sci.* 156, 656-65(1918).—Small doses of HCl at frequent intervals are advised. No stimulation of the mucosa was observed. W. MORSE.

**Lactic acid in the gastric contents.** L. PRON. *Compt. rend. soc. biol.* 81, 468-9 (1918).—Examn. of a large no. of gastric contents free from alimentary debris (during fast) showed a considerable preponderance of positive Uffelmann reactions when free HCl was present and a practically equal no. of positive and negative results when free HCl was absent. Somewhat similar results were obtained with a smaller no. of gastric contents examd. after an Ewald test meal. In a no. of cases of alimentary retention through stenosis of the pylorus lactic acid was detected less frequently than in the above instances with normal pylorus, the reaction being negative in the majority of cases with free HCl and positive in the majority of the very small no. of cases without free HCl. These results confirm P.'s previous observation (regarded as doubtful in view of the results of Gérard and Regnault—cf. C. A. 13, 458) that lactic acid is of extremely frequent occurrence in the gastric contents and especially in the free HCl gastric content of fast. The positive Uffelmann reactions cannot be attributed to the use of glycerol (as pointed out by G. and R.) employed for moistening the tube used for withdrawal of gastric contents, since no glycerol was used in the present cases. Contrary to the view of Timbal and others the presence or absence of lactic acid in the free HCl gastric contents of fast has no significance so far as occurrence of ulcer is concerned. The following slight modification of the technic of the Uffelmann reaction is recommended. Instead of pouring several cc. of gastric liquid into the mixt. of  $H_2O$ ,  $Fe_2Cl_6$  and  $PhOH$ , allow a small portion of gastric liquid to flow on the surface of the reagent and observe the color produced as the liquid slowly drops to the bottom of the test tube. When the reaction is positive a characteristic reddish fawn-colored train is produced; when the color is yellow the reaction is regarded as doubtful. H. S. PAINE.

**Studies of the osmotic-chemical equilibrium between the liquid of blood corpuscles and the serum. I.** H. J. HAMBURGER. *Arch. néerl. de physiol.* 2, 636-43; *Chem. Weekblad* 15, 1360(1918).—The liquid obtained by pressing red corpuscles through infusorial earth and that obtained by the freezing out method both have a lower osmotic pressure than that of the serum. The ultrafiltrate from the pressed-out liquid has a still lower osmotic pressure. This is attributed to absorption of electrolytes from the stroma. These are preliminary expts. in a study of the question whether or not K predominates in the red corpuscles and Na in the serum. JULIAN F. SMITH.

**The influence of calcium salts on the processes of phagocytosis.** J. DE HAAN. *Arch. néerl. de physiol.* 2, 674-84; *Chem. Weekblad* 15, 1361(1918).—To find whether the influence of Ca salts on phagocytosis in the horse is similarly exerted on the leucocytes of other animals the rabbit was studied. The influence of Ca salts was found to be analogous in both cases. JULIAN F. SMITH.

#### G. PATHOLOGY.

H. GIDEON WELLS AND ANDREW HUNTER.

**Studies on the antitypsin of serum.** B. FUGIMOTO. *J. Immunology* 3, 51-66 (1918).—The temps. that must be applied for the inactivation of antitypsin of serums differ not according to individuality but according to species and lie between 65°

and 75°. As serums never coagulate at 75° in their lower concn., it is better at first to dil. them and then heat at 75° for 10-30 mins. for their complete inactivation. The antitryptic action of urine cannot be affected as easily as that of serums. Urine must be heated at 100° for one hour for its complete inactivation. The antitrypsin of serum cannot be inactivated by shaking and it is not dialyzable. Both the globulin and albumin fractions of serum are antitryptic, but the former is less so than the latter. The ether ext. of serum has no antitryptic action but cryst. serum albumin is antitryptic.

GEO. T. CALDWELL.

**The immunologic properties of uveal pigment.** A. C. WOODS. *J. Immunology* 3, 75-91(1918).—The pigment of the uveal tract of the eye acts as antigen in homologous animals and in the immunologic reactions in organ but not species specificity. These findings can be demonstrated by the complement fixation reaction with the sera of properly immunized animals. In the case of the perfusion expts., the anaphylactic reaction is manifested by a marked contraction of the pupil, and the occurrence of small hemorrhages in the fundus. This reaction was used to study the antigenic properties of uveal pigment, and the results shown by complement fixation were confirmed.

GEO. T. CALDWELL.

**Experiments upon the passive transfer of antibodies from the blood to the cerebrospinal fluid.** J. A. KOLMER AND S. SEKIGUCHI. *Univ. Pa. J. Immunology* 3, 101-7 (1918).—The removal of blood from normal dogs followed by the intravenous injection of human syphilitic serum in amts. varying from 30 to 50 cc. per kg. of body wt. was followed by the presence of small amts. of syphilis reagin (the antibody concerned in the Wassermann reaction) in the cerebrospinal fluid. This appeared as early as 3 hrs. after transfusion with syphilitic serum and apparently disappeared after 22-4 hrs. as detd. by completely negative Wassermann reactions. After irrigation of the spinal meninges by the preliminary injection of sterile horse serum the amt. of reagin gaining access to the cerebrospinal fluid after transfusion appeared to be somewhat greater. The intravenous injection of dog typhoid immune serum into a normal dog in amt. of about 30 cc. per kg. of body wt. was followed by the appearance of traces of agglutinin in the cerebrospinal fluid within 3 hrs. after transfusion; fluid removed 48 hrs. later was free from agglutinin.

GEO. T. CALDWELL.

**A new method of estimating the antitryptic index of blood serum.** T. B. ROBERTSON AND S. HANSON. *Univ. Calif. J. Immunology* 3, 131-8(1918).—It is shown that for varying proportions of an antitrypsin ( $A$ ) added to a specified amt. of trypsin (regarded as unity) the relation  $T/[A(I - T)] = C$  holds good for any given serum,  $T$  being the proportion of the trypsin neutralized by the serum and  $C$  a const. which is a direct measure of the number of mols. of antitrypsin contained in a specified vol. of serum. The mol. concn. of antitrypsin in blood serum is in great excess of the mol. concn. of proteolytically active material in a 1% soln. of Gruebler's trypsin.

GEO. T. CALDWELL.

**The non-influence of injections of trypsin upon the protein quotient in blood serum.** S. HANSON. *Univ. Calif. J. Immunology* 3, 139-46(1918).—The normal variation in the antitryptic index is very marked in any particular rabbit, and is even greater in different animals. The progress of immune body production against trypsin is very peculiar in that at first there is a marked fall in the antitrypsin, followed soon, however, by rather a sudden rise which is at best only 300% above the normal variation. At this level the antibody content remains approx. stationary for a comparatively brief period and then rapidly returns to normal, in spite of continued periodical injections of trypsin. Immunity to pancreas trypsin appears to cause no change in the protein quotient. This fact may serve as additional evidence in favor of the recently

emphasized view that immunity is non-dependent on the concn. of the serum proteins.

GEO. T. CALDWELL.

A study of the immunizing properties of bacterial vaccines prepared after various methods. M. W. PERRY AND JOHN A. KOLMER. *J. Immunology* 3, 247-59(1918).—All vaccines of *B. typhosus* prepd. in various ways and including living, autolyze, chem. and heat-killed and alc.-killed sediment usually produced slight leucocytosis and slight increase of temp. when administered to rabbits by subcutaneous injection in doses according to body wt. and comparable to those given to persons. The alc.-killed sensitized sediment produced these non-sp. reactions in highest degree. Agglutinin and complement-fixing antibodies were produced in highest degree by administration of living and autolyzed vaccine. An antigen of *B. typhosus* prepd. by cultivating the organism in plain neutral broth for 48 hrs. and sterilizing the culture with 0.1 % of commercial formalin (40%) in a cold dark place for a period of 4-5 days, proved of particular value in macroscopic agglutination tests.

GEO. T. CALDWELL.

Complement fixation with protein substances. R. L. KAHN AND A. MCNEIL. *J. Immunology* 3, 277-93(1918).—Gelatin, racemized proteins, proteoses, Vaughan's sol. poison from casein, insol. residue remaining from the prepn. of Vaughan's poison from casein and animal tissues, did not produce complement-fixing antibodies when injected into rabbits. What has been found to be true in the case of other immunity reactions, appears to be true, also, in the case of the complement-fixation reaction, namely, that the specificity of the complement-fixation reaction depends upon the chem. structure of the protein mol. and if the mol. be split or modified by racemization, its sp. complement-binding power is lost.

GEO. T. CALDWELL.

A contribution to the study of the complement fixation reaction in tuberculosis. M. A. WILSON. New York. *J. Immunology* 3, 345-50(1918).—Not all guinea-pig serums are efficient for tuberculosis complement fixation. The serum from each guinea pig should be tested for fixability with tuberculous antigen plus tuberculosis serum before pooling the complement for diagnostic tests.

GEO. T. CALDWELL.

A contribution to the study of the complement-fixation reaction for tuberculosis. H. VON WEDEL. New York. *J. Immunology* 3, 351-69(1918).—Pooled complement from at least six guinea pigs should be used in making the tests, as the complement from single pigs should be tested for its complement-fixation value with known positive serums. Double the original Wassermann amt. of patient's serum should be used and no report should be made until the serum has been tested after having been kept under sterile conditions in the ice chest for from 4 to 6 days, preferably 6 days. These results seem to indicate that if these modifications are used, 100% of non-tuberculous cases will give abs. negative results; nearly 100% of the primary and active cases will give positive results with the exception of the dying cases; and about 35% of the partially inactive and inactive cases will give only weak positive results.

GEO. T. CALDWELL.

The role of immunity in the conduct of the present war. J. A. KOLMER. Phila. *J. Immunology* 3, 371-4(1918).—An address.

GEO. T. CALDWELL.

The mode of action *in vitro* of the preparation of hemolytic antibodies. A. K. BALLS AND J. W. KARNS. New York. *J. Immunology* 3, 375-87(1918).—The work was undertaken with the idea of studying the mechanism of amboceptor action *in vitro* and of ascertaining, if possible, what part of the red blood cells is responsible for their antigenic property. *In vitro*, as hemolysis proceeds, the total amt. of amboceptor is const. As the stroma of the laked red blood cells increases in amt. the latter become less and less satd. with amboceptor and so split off less of it by dissociation, thus causing the velocity of hemolysis to decrease. *In vivo*, the stroma produces sp. hemolytic and agglutinative bodies of high titer. Alc. and ether exts. of the stroma do not bind amboceptor *in vitro*.

The ext. of stroma with alk. physiol. salt soln. (0.2% NaOH) does bind amboceptor *in vitro* and on injection causes the development of sp. hemolysins but not of agglutinins. This alk. ext. contains nucleoprotein, but not simple albumin or globulin. It also contains lipoids but these probably are not essential to its antigenic function. The presence or absence of the anaphylactic reaction is not a certain criterion for specificity when nucleoproteins are used as antigens. Hemolysins, showing species specificity, were present in the absence of anaphylaxis. GEO. T. CALDWELL.

Studies in pneumonia. VIII. A skin reaction to pneumotoxin. C. WEISS AND J. A. KOLMER. *J. Immunology* 3, 395-411 (1918).—See C. A. 12, 2619. G. T. C.

A method of preparing bacterial antigens. J. C. SMALL. *J. Immunology* 3, 413-22 (1918).—The efficiency of a bacterial antigen is raised by the removal of the  $\text{CHCl}_3\text{-Et}_2\text{O}$ -sol. constituents of the dried bacteria. Standardized dry antigen preps. can be made and rendered available for work over long periods. The complement deviation reaction has limited uses in the differentiation of type within the bacterial groups studied. The failure to differentiate type is more pronounced in the pneumococcus and in the meningococcus groups. In the typhoid group the striking thing is the degree of complement deviation by the typhoid antigen in cross titration with the paratyphoid bacilli A and B serums. Paratyphoid B is less efficient than paratyphoid A in fixing complement with typhoid immune serum. In the dysentery group the results rather sharply differentiate the Shiga from the Flexner and "Y" types.

GEO. T. CALDWELL.

A study of saponin hemolysis. T. FURUHATA. Tokyo. *J. Immunology* 3, 423-34 (1918).—The hemolytic action of saponin or sapotoxin is, to a certain extent, inhibited in a non-electrolyte medium. As nonelectrolyte media isotonic solns. of glucose and of sucrose were employed. As the viscosity of the medium increases there is an increased inhibition of the hemolysis by saponin. Ions of various salts favor saponin hemolysis, except  $(\text{NH}_4)_2\text{SO}_4$  which can alter the red cells in higher concn.  $\text{BaCl}_2$  and  $\text{CaCl}_2$  are indifferent. The resistance of red blood cells against saponin is different in the different species of animals, the order of increasing resistance being horse, guinea pig, rabbit, pig, sheep and pigeon among the red blood cells tested against jegosaponin.

GEO. T. CALDWELL.

Specific fats as factors in immune processes. C. C. WARDEN. Univ. Mich. *J. Infec. Dis.* 23, 504-21 (1918); cf. C. A. 12, 1483.—The fat complexes of certain bacteria (typhoid, gonococcus, and pneumococcus) and other cells (red blood cells of sheep blood), obtained either from the cells or assembled artificially, are capable of replacing the cells themselves in the production of sp. antibodies in the blood of rabbits injected with them. The specificity of the antibodies obtained by the injection of cells probably depends in part or wholly on the configuration of the fats constituting the bulk of the cell surfaces.

JULIAN H. LEWIS.

Studies on cholesterol. V. The blood cholesterol in malignant disease and the effect of radium on the blood cholesterol. GEORGINE LUDEN. Rochester, Minn. *J. Lab. Clin. Med.* 4, 849-62 (1918).—See C. A. 13, 37. GEO. T. CALDWELL.

Immunity in tissue transplantation. IV. The influence of immune serum upon the reactions about transplanted tissues. M. S. FLEISHER. St. Louis. *J. Med. Res.* 39, 1-14 (1918); cf. C. A. 12, 2365.—In passively immunized animals the same reactions occur about homoiotransplants as in normal animals. About heterotransplants there is possibly a slower clearing of the peripheral portion of the tissue of leucocytes but otherwise the reactions are like those in normal animals. G. T. CALDWELL.

Studies in pneumonia. IX. The properties of pneumotoxin and its probable function in the pathology of lobar pneumonia. C. WEISS. Phila. *J. Med. Res.*

39, 103-22(1918).—Living virulent washed pneumococci when dissolved in dil. soln. of sodium choleate liberate an endocellular hemolytic toxin (pneumotoxin). Different preps. of pneumotoxin vary considerably in their toxicity. Sp. pneumococcal substances such as anti-pneumococcus horse serum or solns. of various cinchona derivs. will not neutralize the toxicity of pneumotoxin either *in vivo* or *in vitro*. This substance is very labile, much or all of its activity being lost upon aging, Berkefeld filtration or heating. It is a true protein giving all the color reactions, being digested by trypsin, serving as an antigen, producing an antihemolytic serum, and a state of allergy in sensitized guinea pigs. It produces a sp. precipitin reaction with the corresponding type anti-pneumococcus horse serum. It is present in pneumonic lung exudates and is demonstrable by means of a skin test in acute lobar pneumonia patients. Hemoptysis and icterus in pneumonia are regarded as partly or entirely the result of that hemolytic activity of pneumotoxin. GEO. T. CALDWELL.

**The standardization of the Wassermann reaction.** W. D'ESTE EMERY. *Lancet* 1918, II, 547-52.—By extg. sheep's heart with abs. alc. for 7 to 10 days an antigen can be prepd. which is almost abs. const. In actual practice three exts. prepd. from three different hearts are kept separate and later mixed and cholesterol is added before using. Syphilitic sera prepd. aseptically and free from foreign materials remain const. for at least a month and probably longer, at room temp. The use of such sera affords an easy means by which an experimenter can obtain comparable results. Accurate standardization of such sera will enable workers by any technic to obtain comparable results. GEO. T. CALDWELL.

**The agglutinating properties of certain sera against *B. typhosus*, *B. paratyphosus* A and B.** T. T. O'FARRELL. Dublin. *Lancet* 1918, II, 626-7.—The results obtained with 496 sera of inoculated men show that the number of sera which fail to agglutinate *B. typhosus* increases as the time following the last inoculation is prolonged. There is a sudden increase in the number of negative sera at the end of 15 months. In so far as agglutinins can be taken as an index of immunity against infection, the immunity is high for the first 3 months after inoculation, moderate from 4 to 15 months and low thereafter. The typhoid agglutinin content is higher in mixed vaccine cases, at practically all periods, than in cases inoculated with typhoid vaccine alone. G. T. C.

**The use of "antigens" in diagnosis by the Wassermann reaction; the necessity for further investigation.** C. W. BROWNING AND E. L. KENNEWAY. *Lancet* 1918, II, 733-5.—In the absence of an ideal antigen a proportion of weak positive reactions will be missed if only a single antigen be used in performing the Wassermann test. It is advised that parallel tests be made with heart cholesterol and liver lecithin plus cholesterol antigens. Where tests were performed with only one antigen, all sera should be preserved so that if a positive reaction fails to be obtained in cases which are clinically suspicious, the test may be repeated with the other antigen. GEO. T. CALDWELL.

**Postdiphtheritic paralysis and the spinal fluid findings.** JOSEPH C. REGAN. Kingston Ave. Hospital for Contagious Diseases, New York City. *Arch. Pediatrics* 35, 641-5(1918).—In 6 cases (including 4 fatal cases) of this disease, the findings were normal in all instances, except a slight increase in the albumin and globulin content of the fluid in 1 patient. The cell count never exceeded 7 per mm.<sup>3</sup>; lymphocytes predominated. Reduction of Fehling soln. was normal. The fluid was clear, transparent, and usually under a slight hypertension. "The spinal fluids were taken at various stages in the disease from a period shortly after paralysis developed in some cases, until just preceding or following death in others. It seemed rather doubtful, therefore, that a transient meningeal reaction could exist and yet leave no trace at the diverse periods of the disease in which punctures were performed. All the patients

in the series were suffering from a grave and usually mortal type of paralysis, a type in which central involvement of the nervous system could be most expected."

JOSEPH S. HEPBURN.

**Epidemic of dengue among soldiers in Formosa.** S. HANABUSA. *Gunidan Zasshi* 70, 578-94(1917); *Jap. Med. Literature* 3, 72(1918).—In 88 cases of dengue, the diazo reaction of the urine was positive in 81.2%; the positive reaction was closely connected with the appearance of the exanthem, reached its acme at the same time as, and disappeared with, the latter. Albumin occurred in the urine of 8.3% of the cases.

JOSEPH S. HEPBURN.

**Calcium soap deposit in the liver during diabetes.** R. HAGIWARA. *Iji Shimbum* 981, 1201-2(1917); *Jap. Med. Literature* 3, 62(1918).—At the autopsy of a patient who had shown acetonuria, deposits of Ca soaps were found in the liver such as occur in fat necrosis as a result of pancreatic lesions. No lesion could be demonstrated in the latter organ, and no explanation could be found for the deposits. J. S. H.

**Experimental study of sera and placental extract in eclampsia.** I. OBATA. *Tokyo Igakukai Zasshi* 31, No. 19, 37-61(1917); *Jap. Med. Literature* 3, 74-5(1918).—The placental exts. of normal women apparently differ in no way from those of eclamptic women. Normal serum has a detoxicating action on placental ext.; this property is markedly decreased in the sera of eclamptic women, but is rapidly regained, as a rule, within 2 or 3 days after delivery. The decreased detoxicating action of the serum is a cause and not the result of eclamptic seizures. On injection of placental exts. into animals, the phenomena produced more or less resembled those of eclampsia. Gradual introduction of placental ext. (e. g., during a period of 12 days) produced far more profound pathological changes than a single, large dose: fatty changes in liver, kidneys, and heart; increased coagulability of the blood; parenchymatous bleeding; thrombus formation in liver and lungs; and more or less evidence of profound intoxication such as occurs in eclampsia. It is concluded that eclampsia is a temporary lowering of the power of the maternal serum to detoxicate placental ext. JOSEPH S. HEPBURN.

**Placental antigen in its relation to serum of pregnant women.** G. FUJIMURA AND T. HIROSE. *Tokyo Igakukai Zasshi* 31, No. 24, appendix, pp. 18(1917); *Jap. Med. Literature* 3, 76(1918).—The serum of pregnant women contains antibodies which bind complement in the presence of placental ext. These antibodies are rather closely specific for pregnancy, disappearing approx. 3 weeks from the time of delivery; they are distinct from the protective enzymes, and have no relation to any complicating disease. JOSEPH S. HEPBURN.

**Toxicity of immune serum.** Y. YAMADA. *Tokyo Igakukai Zasshi* 32, No. 1, 1-32(1918); *Jap. Med. Literature* 3, 76-7(1918).—Anti-goat dog serum was used for injection into guinea pigs. Goat cells which had been heated to 120° retained the power to produce a toxic and hemolytic serum. Intraperitoneal injection of the serum failed to produce demonstrable intravital dissolution of the guinea-pig corpuscles; it was immediately followed by intense symptoms, thereby differing from serum anaphylaxis; repeated intraperitoneal injection of sublethal doses of serum eventually produced immunity, and anaphylaxis was no longer possible. Anaphylatoxin could not be demonstrated in (a) blood of guinea pigs in the anaphylactoid state, or (b) a mixt. of goat-blood-immune dog serum, emulsion of guinea-pig organs, and complement. The titer of hemolytic action did not run parallel to the temp. curve obtained after injection of the serum. The toxicity of the serum was greatly influenced by the mode of its withdrawal, and by the period of time elapsing thereafter, and was quite resistant toward the action of acids and alkalies. The albumin fraction, and not the globulin, was toxic. Intraperitoneal injection of adrenaline inhibited the anaphyl-

actoid reaction to a certain extent. The anaphylactoid reaction had no relation to serum sickness, and was not a manifestation of true anaphylaxis. J. S. HEPBURN.

**Clinical study of hyperemesis gravidarum.** N. KUJI. *Tokyo Igakukai Zasshi* 32, No. 4, 1-49(1918); *Jap. Med. Literature* 3, 78(1918).—Observations were made on 17 patients. The temp., and positive albumin and diazo reactions in the urine have no prognostic value; a decrease in the vol. of the urine is not a measure of the severity of the disease. When an intravenous saline infusion is given, the vol. of the urine should increase, and its sp. gr. should *not* be persistently low; otherwise conditions are serious. In serious cases acetone and diacetic acid are usually present in the urine, and its  $\text{NH}_3$  content is increased. The % and amt. of total urinary N and the ratio total N:total S decrease; the S decreases in proportion to the severity of the disease, and increases with recovery. Inorganic S usually decreases, in severe cases, to less than half the total S; conjugate sulfates are not materially changed; neutral S definitely increases, in fulminant cases both absolutely and in comparison with the total figure; in severe cases it coincides more or less closely with the value for conjugate sulfates. Total P is always low; and its ratio to total N becomes less the more severe the condition. The PhOH figure usually is unchanged, but, as a rule shows a sudden and marked rise just before death. "These findings are not those of starvation, in which the intestinal putrefaction is in abeyance, but they signify rather a change in the process of oxidation in the body, and a disturbance in the function of the liver which in turn is doubtless the result of a toxic process." JOSEPH S. HEPBURN.

**Renal function as measured by the elimination of fluids, salts and nitrogen and specific gravity of the urine. II. The effect of high and low normal diets.** H. O. MOSENTHAL. Atlanta. *Arch. Intern. Med.* 22, 770-804(1918).—The expts. showed that certain characteristics as indicated by sp. gr. of all specimens and vol. of the night urine are preserved regardless of diet. There are periods of polyuria with low sp. gr. alternating with oliguria and high sp. gr. If only small amts. of water are taken the urine output is low, const. from one 2-hour period to the next and the sp. gr. becomes fixed at a high level. Tests on high- and low-protein diets were carried out on individuals suffering from impairment of the renal function. Nocturnal polyuria occurs more frequently on high- than on low-protein diet. There is apparently an effort to eliminate solids by means of polyuria, when the concn. of solids is no longer possible. Nocturnal polyuria on low-protein diet is a much graver sign of renal insufficiency than when it occurs on high-protein diet. When edema was present there were rapid changes from oliguria to polyuria. In such cases the clinical aspect of the case must be taken into consideration and not the elimination of the urine alone. F. HULTON-FRANKEL.

**The coagulation of the blood and anaphylactic shock.** HAROLD A. BULGER. Harvard Med. School, Boston. *J. Infect. Dis.* 23, 522-32(1918).—The changes in the coagulability of the blood during anaphylactic shock are due to changes in that stage of the coagulation process at which thrombin is formed through the interaction of prothrombin, Ca, thromboplastin and antithrombin(?). These changes are probably due to variations in thromboplastin. Antithrombin changes are not great. In some animals there may be an increase in antithrombin which would aid in retarding the coagulation of the blood. There is no increase in antithrombin in rabbits. There was a marked increase in the rate of fibrinolysis after anaphylactic and peptone shock.

JULIAN H. LEWIS.

**The Bartlett and O'Shansky modification of the Wassermann reaction.** E. H. REUDIGER. Bismarck, N. D. *J. Infect. Dis.* 23, 533-36(1918).—Compared with the regular method used by the author, the Bartlett and O'Shansky modification of the Wassermann reaction (*C. A.* 11, 3289; 12, 64, 383), designed to reduce the time used for the reaction, gives by far too many negative results.

JULIAN H. LEWIS.

**Failure to obtain potent serum from a horse injected with poliomyelitic material.** SAMUEL G. DIXON AND JAMES B. RUCKER, JR. *J. Infect. Dis.* 23, 543-6(1918).—Protective substances could not be demonstrated in the serum of a horse injected repeatedly over a period of 7 mos. with the unheated filtrate of a 1:50 emulsion of poliomyelitic brain and cord. JULIAN H. LEWIS.

**Studies in the metabolism of pathogenic *Actinomyces* (*Streptothrices*).** I. SELMAN A. WAXSMAN. Cutter Biol. Lab., Berkeley, Calif. *J. Infect. Dis.* 23, 547-54 (1918).—The purpose of these expts. is to find a bio-chem. basis of classification of the *Actinomyces*. The present report concerns only the pathogenic form. The observations made are: Blood agar is a very good medium for the growth of pathogenic *Actinomyces*, a good growth being obtained in 24-72 hrs. at 37°. The production of hemolysis on blood agar, the liquefaction of blood serum, the clotting and subsequent peptonization of the milk, the liquefaction of gelatin, run parallel; the organism that produces most hemolysis produces liquefaction of the blood serum and gelatin and a greater digestion of milk proteins; the organism that does not produce any hemolysis of the blood does not liquefy the blood serum and the gelatin, does not clot milk and has only a small action on the milk proteins. These characters can be used advantageously in the identification and classification of the *Actinomyces*. Some pathogenic. *Actinomyces* grow readily on synthetic mediums. JULIAN H. LEWIS.

**Immune reactions with diplococci isolated from measles and rubella.** RUTH TUNNICLIFF AND MARY WILMARTH BROWN. John McCormick Inst. for Infect. Dis., Chicago, Ill. *J. Infect. Dis.* 23, 572-7(1918).—Complement-fixing bodies for the diplococci isolated by Tunnicliff from measles and rubella are present in the blood of measles and rubella patients to a slight extent as the symptoms subside. The blood of rabbits injected with various strains of measles and rubella diplococci develops agglutinins and opsonins. Agglutinins are demonstrable in the blood of measles-immune rabbits often in high dilns., both with homologous and heterologous strains. Satisfactory agglutination expts. are not possible as a rule until long after isolation of the diplococcus on account of spontaneous agglutination. Agglutinins are present in the serum of immune rubella rabbits, but generally only for the homologous strains. Sp. opsonins are demonstrable in the blood of immune measles and rubella rabbits in high dilns., and furnish the easiest and most reliable immunological method so far found, to differentiate measles and rubella diplococci from each other and from other non-hemolytic diplococci and streptococci. JULIAN H. LEWIS.

**The toxicity of emetine hydrochloride, with special reference to the comparative toxicity of various market preparations.** GLEASON C. LAKE. Washington, D. C., U. S. Public Health Surv., Hyg. Lab., *Bull.* 113(1918).—The toxicity of emetine-HCl was studied in rabbits, white rats, and white mice, with the result that, with the same prepn. of the drug, a widely variable individual susceptibility was found in each of these species. Rowntree and Levy's work shows that the same holds true for cats and dogs. From the small amt. of data obtainable it seems probable that in man the range of susceptibility to emetine poisoning is fully as great as in exptl. animals, and perhaps more so, in so far as it has to do with cases of amebic dysentery, where there is always present a pathol. condition varying in intensity. The pathol. changes most often produced in exptl. animals are acute degenerative changes in the parenchymatous organs. Expts. carried on in a large no. of white mice failed to show any considerable variation in the toxicity of 12 market prepns., and make it highly probable that such apparent variations are largely attributable to the widely varying susceptibility of animals to the drugs. JULIAN H. LEWIS.

**Blood-pressure and kidney function findings in orthostatic albuminuria.** E. H.

MASON AND R. J. ERICKSON. *Am. J. Med. Sci.* 156, 643-656(1918).—Low pulse pressure is the cause of the albuminuria. W. MORSE.

**Sensitization and anaphylactic shock in guinea pigs by repeated injections of copper glycocholate.** A. CH. HOLLANDE. *Compt. rend. soc. biol.* 81, 58-61(1918).—Guinea pigs (300-500 g. wt.) died of anaphylactic shock after repeated intracardiac and intraperitoneal injections (1.5 cc. daily for a max. of 6 days) of a physiol. NaCl soln. containing 0.50 g. of Cu glycocholate per 100 cc. Some of the animals which received intracardiac injections died after the 3rd injection, while those which received intraperitoneal injections only showed anaphylactic shock after the 4th injection. Intracardiac or intraperitoneal injection of 7.5 mg. of Cu glycocholate produced no untoward results in unsensitized animals. It was possible to de-anaphylactize the anaphylactized animals by means of the Besredka method. In view of the fact that guinea pigs may be anaphylactized by Cu glycocholate and polypeptides such as diglycylglycine and triglycine (cf. expts. of Zung and Diakonov) composed of several mols. of glycine but not by glycoll itself, H. concludes that sensitization is probably a function of the  $\text{NH}_2$  group and that sensitization and particularly the production of anaphylactic shock may require the presence of at least 2  $\text{NH}_2$  groups in the compd. injected. At any rate, the chem. constitution of the peptide mol. plays an important role in establishing anaphylaxis. H. S. PAINÉ.

**Disappearance of the lipocholesterol deposits of the human suprarenal during motor activity.** M. LAIGNEL-LAVASTINE. *Compt. rend. soc. biol.* 81, 324-5(1918).—The suprarenals of patients with senile dementia, dementia praecox, maniacal excitation and pneumonia who died after at least 5 days of sustained and intense motor activity were characterized by total absence of lipocholesterol deposits in the cortex. Decrease of lipocholesterol content was not so pronounced in patients with the above affections but with less motor activity. These results have a bearing on the importance of the myotonic function of the suprarenals. Decrease in lipocholesterol content cannot, however, be attributed solely to sustained motor activity. H. S. PAINÉ.

**Effects of certain chemical reagents on the endotoxin and antigenic power of the Eberth bacillus.** L. BLAIZOT. *Compt. rend. soc. biol.* 81, 356-8(1918).—B. attempted to ascertain whether it is possible chemically to destroy the endotoxin of the typhoid bacillus without destroying its immunizing power. An 18-hr. culture of typhoid bacilli on gelose was washed with distd.  $\text{H}_2\text{O}$  and subjected in the presence of distd.  $\text{H}_2\text{O}$  to the action of the following reagents: (oxidizing agents) 1:100 chromic acid, 1:3  $\text{HNO}_3$ , 1:2  $\text{H}_2\text{O}_2$ ; (reducing agents) 1:10  $\text{HCHO}$ , 1:10 hydroquinone; (lipoid solvents) abs. alc., Na alcoholate (the 2 latter acted on bacteria free from  $\text{H}_2\text{O}$ ). Contact between bacteria and reagents was maintained 24 hrs. at  $37^\circ$ . All of the reagents reduced bacterial toxicity, but none of them entirely destroyed the endotoxin. The latter showed greater resistance to the oxidizing than to the reducing agents. The endotoxin showed considerable resistance to abs. alc. but was almost totally destroyed by Na alcoholate. This effect of alks. is also produced in an aq. medium as was shown by the action of 0.1 *N* NaOH. The injurious effect of the various reagents on the endotoxin was greater than that produced by heating at  $58^\circ$  for 20 mins., but less than that due to heating at  $120^\circ$  for the same period, no febrile reaction being produced in rabbits after injection of bacteria subjected to the latter treatment. The endotoxin of bacteria previously treated with  $\text{HCHO}$  was likewise thermolabile at  $120^\circ$ . Bacteria treated with  $\text{H}_2\text{O}_2$ ,  $\text{HNO}_3$ ,  $\text{HCHO}$  and hydroquinone and by heating at  $58^\circ$  and  $120^\circ$  immunized rabbits against amts. of living bacilli which killed the controls in 24 hrs. Bacteria treated successively with  $\text{HNO}_3$  and very dil. NaOH soln. and those treated with hydroquinone or heated at  $120^\circ$  were capable of producing immunity without causing the appearance of agglutinins. The agglutinating power of sera due

to injection of bacteria subjected to varying treatment was as follows: heating at  $58^{\circ}$ , 1:2,500-12,000;  $\text{HCHO}$ , 1:1000-5,000;  $\text{H}_2\text{O}_2$ , 1:2,500; chromic acid, 1:500-1000; abs. alc., *nil*; Na alcoholate, *nil*;  $\text{HCHO}$  followed by heating at  $120^{\circ}$ , *nil*. When the bacteria were treated with 1:3  $\text{HNO}_3$  and then centrifuged, washed with distd.  $\text{H}_2\text{O}$ , dild. to a definite vol. and then treated with dil.  $\text{NaOH}$  soln. added drop by drop a point was reached where the addition of another drop of  $\text{NaOH}$  soln. suddenly clarified the emulsion and produced the xanthoproteic reaction. After centrifuging, a clear soln. was obtained which was capable of immunizing rabbits without causing formation of agglutinins.  $\text{Me}_2\text{CO}$  pptd. from this soln. a yellow mass which carried with it the endotoxin and the immunizing property, the portion sol. in  $\text{Me}_2\text{CO}$  exhibiting neither toxic nor immunizing action.

H. S. PAINE.

**Antipepsin of the serum.** M. RUBINSTEIN. *Compt. rend. soc. biol.* 81, 511-2 (1918).—A normal serum (human, rabbit, guinea pig, cattle) dild. 1:10 with physiol.  $\text{NaCl}$  soln. and heated to  $100^{\circ}$  not only preserves its antipeptic action (as shown by Briot, Perin and Jochmann and Kantorowicz), but the inhibiting action also becomes more pronounced as the temp. increases. R. attributes this change to the fact that the serum after being heated neutralizes a portion of the free  $\text{HCl}$  which is requisite for the activity of the pepsin. Egg white, as well as blood serum, exhibits this antipeptic action; this anti-enzymic action of egg white is also intensified by heating. In so far as the antipepsin of immunization is concerned it is difficult to increase the antipeptic action of the serum in rabbits in spite of the presence in the serum of the immunized animals of antibodies detectable by the precipitin and fixation reactions (these antibodies may, on the whole, be regarded as directed against the impurities of com. pepsin). With the goose and chicken it is possible with difficulty to increase the antipeptic action of the serum (after long prepn.), but this artificial "antipepsin" as well as the normal "antipepsin" is intensified by heating to  $100^{\circ}$ . These results are to be considered in connection with Linossier's conclusion that the effect produced by heating to  $100^{\circ}$  is inconsistent with the hypothesis of the existence of a sp. antibody and that the inhibiting effect is due to the mutual reaction of the colloids of the serum and digestive liquid.

H. S. PAINE.

**Thermolability of syphilitic antibodies.** P. GÉRARD. *Compt. rend. soc. biol.* 81, 835-7 (1918).—Syphilitic antibodies are thermolabile in varying degree when heated at  $56^{\circ}$ . In some cases the capacity for fixing complement was reduced about  $\frac{1}{4}$ , while in other cases it was reduced as much as  $\frac{3}{4}$ . The beginning of this degradation was distinctly observed at  $45^{\circ}$  and often reached a value of 50% after heating  $\frac{1}{2}$  hr. The same degree of degradation was obtained after 24-48 hrs. at  $37^{\circ}$ . It was not detd. whether the varying degree of thermolability of syphilitic antibodies corresponded to definite periods of the disease. This thermolability is also shown by other antibodies, especially the natural human anti-sheep hemolysins; anti-sheep hemolysins produced by injection of erythrocytes in rabbits are much less sensitive. It is advisable, in performing the Wassermann reaction, to det. the maxima of fixation and to differentiate with respect to injection between various reactions which have been simply recorded as (+++). The reactions obtained with heated and unheated sera should be compared. In order to avoid as far as possible the destruction of antibodies the period of heating at  $56^{\circ}$  for destruction of complement should be reduced from  $\frac{1}{2}$  hr. to  $\frac{1}{4}$  hr.; the latter period is ample.

H. S. PAINE.

**Anergy in influenza.** ROBERT DEBRÉ. *Compt. rend. soc. biol.* 81, 913-4 (1918).—Expts. with 100 influenza patients showed a condition of anergy to exist in 72 cases, as compared with its occurrence in 90% of cases of measles (Netter and Porak); this was shown by using another antigen, *i. e.*, smallpox vaccine. The frequent occurrence and serious character of the secondary infections of influenza are probably due to this

condition and the relative inefficacy of antipneumococcic and anti-streptococcic sera, even when used in large doses, may likewise be due in part to the same condition. The biological resemblance between influenza and measles may possibly be associated with an etiological resemblance; the unknown agent of influenza is probably a filterable virus as in the case of measles.

H. S. PAINE.

## H. PHARMACOLOGY.

ALFRED N. RICHARDS.

Effects of intravenous injections of a colloid (gelatin) upon rabbit sera. G. W. CLARK. Univ. Calif. *J. Immunology* 3, 147-56(1918).—The serum proteins of individual rabbits vary through a wide range and the variation is even greater between different rabbits. Intravenous injection of large amts. of gelatin does not produce any marked change in the ratio of the globulins to the total proteins. The gelatin begins to disappear from the blood immediately after injection and continues to do so at a fairly const. rate, being completely eliminated at some time between 6 and 24 hrs. A hydremic plethora results.

GEO. T. CALDWELL.

The influence of arsphenamine and mercuric chloride upon complement and antibody production. I. TOYAMA AND J. A. KOLMER. Phila. *J. Immunology* 3, 301-16(1918).—The intravenous administration of arsphenamine to normal rabbits in doses varying from 0.01 g. to 0.004 g. per kg. of body wt. did not result in an increased output of immune hemolysin to sheep cells but rather suppressed its production; smaller doses did not appear to retard hemolysin production to sheep and human cells but likewise they did not result in an increase. The smaller doses, however, generally produced a slight increase of agglutinin for sheep and human cells. Similar results were observed with HgCl<sub>2</sub>. A single large dose of arsphenamine (0.06 g. per kg.) administered intravenously to rabbits reduced the hemolytic activity of their sera within a period of 24 hrs. after injection, probably by an influence upon the hemolytic complement. The administration of a smaller dose (0.6 g.) to syphilitic persons as part of their treatment was found generally to produce a depression in the hemolytic activity of the serum as tested 1 hr. after injection, followed by a general increase within 18 hrs. Large doses of arsphenamine and HgCl<sub>2</sub> to rabbits tended to limit agglutinin production for typhoid bacilli; single doses of arsphenamine (0.6 g.) in adults did not influence the amt. of normal typhoid agglutinin in their sera.

GEO. T. CALDWELL.

The clinical pathology of mustard gas (dichlorethylsulfide) poisoning. G. R. HERRMAN. Ann Arbor. *J. Lab. Clin. Med.* 4, 1-30(1918).—Moderately severe and severe cases of mustard gas burns of the skin with some involvement of the upper respiratory tract show after the first week a diminution of the urinary output, increased concn. and acidity of the urine, albuminuria and diminished urea and chloride output. Coincident with these ordinary changes, the blood urea is found to be high, but approaches normal with the improvement in the urinary condition when fluids are forced.

GEO. T. CALDWELL.

The comparative values of some local anesthetics. H. C. HAMILTON. Detroit. *J. Lab. Clin. Med.* 4, 60-8(1918).—As a result of the intracutaneous administration in four cases it is definitely shown that novocaine is about  $\frac{1}{3}$  as efficient as cocaine, while apothesine is practically equal to cocaine in anesthetic value. That both novocaine and apothesine are inferior to cocaine by surface application agrees with clin. evidence which has demonstrated cocaine to be exceptionally rapid in its absorption from mucous surfaces.

GEO. T. CALDWELL.

The salicylates. X. The specificity of the salicylates in rheumatic fever. P. J. HANZLIK, R. W. SCOTT AND P. C. GANCHAT. Cleveland. *J. Lab. Clin. Med.* 4, 112-22(1918).—Salicylate seems to possess no thoroughly demonstrated sp. action in rheu-

matic fever. It is no more than a symptomatic remedy which can be safely administered in very large doses, and represents a very fortunate combination of both antipyretic and analgesic qualities. GEO. T. CALDWELL.

Cocaine poisoning. Report of a case with necropsy. E. KELLERT. Albany, N. Y. *J. Lab. Clin. Med.* 4, 129-32(1918). GEO. T. CALDWELL.

The ocular lesions produced by dichlorethylsulfide (mustard gas). A. S. WARTHIN, C. V. WELLER AND G. R. HERRMANN. *Ann Arbor. J. Lab. Clin. Med.* 4, 785-832 (1918); cf. *C. A.* 12, 2363.—The action of mustard gas upon the cornea and conjunctiva is essentially the same as that upon the skin. The amt. of necrosis produced in the conjunctiva is always less than that in the cornea or epidermis. Exposures to dil. concns. of the vapor produce slight degeneration of the corneal and conjunctival epithelium followed by simple conjunctivitis. Stronger concns. produce more or less complete necrosis of the corneal vertex extending throughout the entire depth of the cornea. No metastatic lesions of the eye could be produced exptly. by applications of mustard gas to other regions of the body, or by subcutaneous or intraperitoneal injections. For the mustard gas conjunctivitis, immediate irrigation with a 0.5 to 1% chlorcosane soln. of dichloramine-T followed by frequent irrigation with satd. boric acid soln. is recommended. GEO. T. CALDWELL.

The treatment of dichlorethylsulfide (mustard gas) injuries. A. S. WARTHIN, C. V. WELLER, L. ROOS AND G. R. HERRMANN. *Ann Arbor. J. Lab. Clin. Med.* 4, 833-48(1918).—Of clinical interest chiefly. GEO. T. CALDWELL.

The pharmacology of alcohol. R. B. WILD. Manchester. *Lancet* 1918, II, 623-5. GEO. T. CALDWELL.

Carrell method in infected war wounds. A. SANTUCCI. *Rend. d. adunanze dell'accad. med.-fis. Fiorentina; Sperimentale* 72, 309-25(1918). M. HEIDELBERGER.

Three-day, or "pappataci" fever. F. MICHELI AND G. SATTA. *Rend. d. adunanze dell'accad. med.-fis. Fiorentina; Sperimentale* 72, 399-400(1918).—Clinical findings are discussed. In cases of marked infection "salts of chemicals" do not show any prophylactic action, while in experimental infections arsenicals have a certain preventive power. An intravenous injection of neosalvarsan given during the 1st day results either in a sudden fall in the temp. or in a diminution of the fever and other symptoms. M. H.

Review of the relative and actual efficiency of medicaments for the sterilization of tooth structures. THOMAS B. HARTZELL. Univ. Minnesota. *J. Nat. Dental Assoc.* 6, 48-56(1919).—A summary of researches conducted by various investigators since 1909. JOSEPH S. HEPBURN.

Statistical study of poisonings in Japan. G. TAKATA AND M. KOMINAMI. *Kyoto Igaku Zasshi* 14, No. 6, 1-130(1917); *Jap. Med. Literature* 3, 63-6(1918).—A study of the 4893 cases of poisoning (suicidal, homicidal, medicinal, and accidental) officially reported in Japan during the years 1913-5. The following were represented by more than 50 cases each:  $K_2Cr_2O_7$ ,  $HgCl_2$ ,  $H_2SO_4$ ,  $HCl$ ,  $As_2O_3$ ,  $HCHO$ ,  $AcOH$ ,  $PhOH$ , morphine, strychnine, and rat poison. Other compds. used were:  $HNO_3$ ,  $KCN$ ,  $NaOH$ ,  $CuSO_4$ ,  $CO_2$ ,  $KMnO_4$ ,  $KOH$ ,  $K_2CrO_4$ ,  $KClO_3$ ,  $Na_2CO_3$ ,  $CHI_3$ ,  $AgNO_3$ ,  $NaNO_3$ ,  $Cu$  acetate, spirits, antifebrin, atropine sulfate, kerosene, sulfonal, heroine-HCl, cocaine, illuminating gas, green powder (probably Paris green). Other poisons recorded are: gold paint, green paint, *Aqua Pruni Armeniaceae*, bean oil, leaves, roots and berries of various plants, mushrooms (42 species), and certain animal foods. Chemicals were ordinarily used for suicidal purposes; the plants were either mistaken for edible ones or eaten, in excessive amt.; the animal foods either were unfit for consumption when eaten or were from the poisonous parts of certain animals. JOSEPH S. HEPBURN.

**Physiological action of tetrodonin, the toxin from the roe of the globe fish.** F. ISHIIHARA. *Tokyo Igakukai Zasshi* 31, No. 12, 12-55(1917); *Jap. Med. Literature* 3, 60(1918); cf. *C. A.* 12, 2020.—Tetrodonin is a cryst. compd., and a powerful nerve poison acting chiefly on the sympathetic system; it leaves the myo-neural junction intact. On injection, it produces a fall in blood pressure and circulatory slowing; the heart is greatly affected by tremors, fibrillation, and agitation; heart block finally occurs. In acting on the pupil, the oculo-motor and sympathetic post-ganglionic fibers are involved, but the endings remain intact. Through interference with the sympathetic, peristalsis is quickened, and secretion of perspiration and saliva is inhibited. Death probably results from a direct action upon the respiratory center, rather than from interference with the phrenic nerve. The toxin, in a concn. of 0.00002%, paralyzes a nerve fiber in 30 min., and a striated muscle in 1.5 hrs.; these tissues can be restored by washing. The toxin has very little action on the smooth muscle of the stomach, intestine, blood vessels, iris and bladder. JOSEPH S. HEPBURN.

**Ulcerative changes in the stomach induced by tobacco extract and nicotine solution.** T. HAYASHI. *Tokyo Igakukai Zasshi* 31, No. 21, 37-65(1917); *Jap. Med. Literature* 3, 60-1(1918).—Aq. exts. of tobacco and a soln. of nicotine neutralized with tartaric acid, were administered daily to guinea pigs by subcutaneous injection, producing poisoning just short of the fatal point. Uniform results were not obtained. A tendency to tolerance was overcome by either an occasional interruption of or an increase in the dosage. The stomach of a guinea pig normally is always full; expts. were made on such animals, and on animals which had been starved overnight. Ulceration of the stomach developed in 35% of the 20 guinea pigs which were given tobacco ext. and were allowed to feed as usual. In the animals which were starved overnight, gastric ulceration developed in 52% of the 25 pigs given tobacco ext., and in 30% of the 10 pigs given neutralized nicotine soln. "The ulcerative lesion produced was uniformly a hemorrhagic erosion, but in the early stages the mucosa was not affected superficially. The lesions were situated more commonly near the pylorus, but occasionally in the fundus. Sometimes there was hemorrhage, but always in the early initial stage there was definite anemia." Observations, made by means of the X-ray on the living animal's stomach after the injection, showed that a cramp-like contraction of the muscularis propria first occurred, producing an intense anemia, followed later by an ulcer. The ulcers were of the same type as those caused by pilocarpine and physostigmine. J. S. H.

**Distribution of iron compounds in the body after intravenous injection.** I. T. YAMADA. *Tokyo Igakukai Zasshi* 32, No. 1, 33-4(1918); *Jap. Med. Literature* 3, 77(1918).—Dogs were fed for ten days on soy bean residue obtained in the manuf. of Tofu or bean curd; then each dog was injected intravenously with 1 g. of ferratin and killed in 30 min. Chem. and histological examn. for Fe was made of the organs and tissues. "Nothing especially new was brought out except that this drug is a good one for exptl. work because its dose of efficiency is far from toxic." JOSEPH S. HEPBURN.

**Electrocardiographic investigation of the action of bufagin, a crystalline principle from the venom of the toad, and a comparison with that of digitalis.** S. SAKAI AND S. SHIMIDZU. *Tokyo Igakukai Zasshi* 31, No. 24, 1-19(1917); *Jap. Med. Literature* 3, 76(1918).—No essential difference in action was found between bufagin and the glucosides of digitalis, except that bufagin exerted a stronger and more toxic action. JOSEPH S. HEPBURN.

**The physiology of the stomach. I. Studies on the control of hunger by drugs.** HARRY GINSBURG AND ISIDOR TUMPOWSKY. Chicago. *Arch. Intern. Med.* 22, 553-570(1918).—Gastric fistulas were produced in 12 dogs; in four both the splanchnics and vagi were cut. The drugs were used on animals with "intact stomachs" with the nerves intact and on "isolated stomachs" having the peripheral nerves sectioned.

Hypodermic injections of atropine sulfate in doses of  $1/80-1/40$  gr. inhibited contractions and counteracted the effect of pilocarpine and eserine in this regard. The action takes place in 5-10 min. and persists for hrs. Since the reaction is the same with the isolated stomach, action is on the myoneural junction. Pilocarpine given hypodermically in doses of  $1/15-1/6$  gr. augments the contractions, at the same time giving a decreased pulse rate. The first dose is absorbed in 7-10 min. and subsequent doses in 5-10 min. The same effect is noticed on the section of the nerves, so pilocarpine is effective even after nerve degeneration. Eserine given subcutaneously has a long latent period; intravenously it produces stimulation which persists for 4 hrs. Similar results with the isolated stomach show that it acts on nerve endings. Cocaine gives profound inhibition with doses of 1 cc. of 0.5% cocaine per kg. Cocaine delays hunger pangs. Camphor as camphorated oil is only effective when administered intramuscularly. In large doses the contractions become more intense and frequent and the period of activity is prolonged. Strychnine furnishes no expl. evidence for its supposed gastric effect. There is a slight increase in hunger contractions. Direct application to Auerbach's ganglia causes stimulation. Amyl nitrate used in 5 minim pearls causes only temporary inhibition. The contractions which follow are not reduced in frequency, intensity or duration. The same inhibition is noticed in animals with nerves sectioned. After removal of the drug, tonus is depressed for a long time and returns gradually. Adrenaline causes prompt and marked inhibition of hunger contractions. Inhibition also occurs with the isolated stomach. Fluid extract of ergot given intravenously causes an increase in spontaneous movements of the alimentary tract. There is a temporary inhibition followed by lowered tonus, although contractions ensued. Fluid pituitary ext. caused an inhibition of short duration.

F. HULTON-FRANKEL.

**The effect of continuous intravenous injections of ethylhydrocuprein on experimental pneumococcus infections in rabbits.** JULIAN H. LEWIS. Chicago. *Arch. Intern. Med.* 22, 593-600(1918).—Ethylhydrocuprein can be injected into rabbits intravenously over long periods at the rate of 10 mg. per kg. per hr. without apparent toxic effects. When injected in this manner for 7 hours, it produces a slight bactericidal effect on the serum. If injected at the rate of 15 mg. per hour for 7 hrs. a greater bactericidal effect is produced. The injection of ethylhydrocupreine does not neutralize the effect of a fatal dose of pneumococcus. This method of administration with a suitable drug ought to be of advantage in the treatment of infections.

F. HULTON-FRANKEL.

**An experimental investigation of the toxicity of certain organic arsenic compounds.** GEORGE B. ROTH. Washington, D. C. U. S. Public Health Service, Hyg. Lab., *Bull.* 113(1918).—The toxicity of American and German salvarsan was tested by intravenous injection into rabbits and rats. On account of the decided variation in the susceptibility of the test animals employed, the only general conclusion which could be drawn from the expts. was that there was no marked variation, if any, in the toxicity of the various preps. examd., and that their toxicity in animals, in a general way, runs parallel with their As content.

JULIAN H. LEWIS.

**The early diagnosis of lead poisoning with special reference to abdominal pain.** GEORGE L. APFELBACH. *Am. J. Med. Sci.* 156, 781-95(1918).—Anemia is an early prognosis datum of Pb poisoning. This is associated with fine tremor. The rise of blood pressure was not constant. Nephritis, arterial disease and pulmonary tuberculosis are common accompaniments.

W. MORSE.

**Chlorinated alum solution for irrigation of infected wounds.** W. MESTREZAT. *Compt. rend. soc. biol.* 81, 504-5(1918).—In prep. this soln. (cf. *C. A.* 12, 232, 233) it is

indispensable that the alum soln. be free from  $\text{NH}_3$ , since  $\text{NH}_4$  salts react with  $\text{HClO}$ . The alum employed may be satisfactorily tested in the following manner: Dissolve 2 g. alum in 20 cc.  $\text{H}_2\text{O}$ , add 20 cc. of 30:100  $\text{NaOH}$  soln., shake, suspend a moistened red litmus paper above the liquid and close the container. The paper should not change color to an appreciable extent within 10 mins. if the alum is acceptable. Many samples of com. alum do not comply with this requirement. The amt. of alum required for prepn. of the chlorinated alum soln. is such that the latter, after diln. with an equal vol. of 20:100 hyposulfite soln., should show an acidity (phenolphthalein indicator) corresponding to 50-150 cc. of 0.1  $N$  soln. per l. The acidity of the final soln. may be tested by mixing 2 cc. horse serum with 6 cc. of the soln.; a soln. of correct acidity should ppt. the serum without causing coagulation *en masse*. Insufficient acidity is corrected by addition of alum and too great acidity by addition of  $\text{NaOH}$  soln. H. S. PAINE.

**Poisoning by water hemlock.** G. A. STUTTERHEIM. *Pharm. Weekblad* 55, 1494-7 (1918).—After some fatal cases of water hemlock poisoning, the poisonous principle *cicutine* was studied. It can be isolated by extg. with  $\text{EtOH}$  containing tartaric acid, and purifying from the soln. by evapg., taking up in  $\text{H}_2\text{O}$  and filtering. The residue may be dissolved again in  $\text{EtOH}$ , and the process repeated till the *cicutine* is pure. It is insol. in  $\text{H}_2\text{O}$ , but sol. in alk., from which it can be repptd. by acid. Atropine is the best antidote found so far. In children, 10 g. of the rhizome may cause death.

JULIAN F. SMITH.

POWERS, EDWIN BOOTH: The Goldfish (*Carassius carassius*) as a Test Animal in the Study of Toxicity. Urbana, Ill.: Univ. of Illinois. 73 pp.

## I. ZOÖLOGY.

R. A. GORTNER.

Artificial production of echinoderm larvae with two water-vascular systems, and also of larvae devoid of a water-vascular system. E. W. MACBRIDE. *Proc. Roy. Soc. London* 90B, 323-48 (1918).—From expts. on larvae of *Echinus miliaris*, it was found that exposure to the action of hypertonic sea water for a week commencing with the 4th day of development caused many of the larvae to develop an additional hydrocele or water-vascular rudiment with the accompanying structures (spines, tentacles, and dental sacs). Starvation of the larvae during the first week of their existence, followed by favorable conditions of food and space, caused many of the larvae to be devoid of hydrocele and certain other organs. The relation of hormones to these abnormalities is discussed.

JOSEPH S. HEPBURN.

The part played by calcium oxide of the shell of the hen egg in the formation of the skeleton of the chick during incubation. C. DELEZENNE AND E. FOURNEAU. *Ann. Inst. Pasteur* 32, 413-29 (1918).—The av. wt. of  $\text{CaO}$  in a fresh hen egg (of about 60 g.) is 0.0354 g.; it is about 0.067 on the 16th day of incubation, 0.129 on the 18th, 0.180 on the 20th, and reaches or even surpasses 0.200 on the 21st day at the time of hatching. The av. wt. per 100 of the  $\text{CaO}$  was 0.340 for the chicks at the time of hatching. The increase of  $\text{CaO}$  in the egg during the incubation is about 500%. In the non-fertilized but incubated hen egg, the wt. of  $\text{CaO}$  per 100 after 21 days is exactly the same as in the fresh egg. No trace of  $\text{CaO}$  has passed from the shell into the interior of the egg. In the egg of the peacock, the incubation period of which is 25 days, the wt. of  $\text{CaO}$  per 100 changes from 0.0964 to 0.457. In duck eggs, whose incubation period is 28 days, the increase in  $\text{CaO}$  is about 400%. The P content is not increased during incubation. These results show that the chick takes from the shell the greater part of the  $\text{CaO}$  necessary for its development and the formation of its skeleton.

GEO. T. CALDWELL.

## 12. FOODS.

W. D. BIGELOW AND F. F. FITZGERALD.

What to teach the public regarding food values. E. V. McCOLLUM. *J. Home Econ.* 10, 195-206(1918); cf. C. A. 12, 1069.—M. points out some of the mistakes made in teaching dietetics to the public. He advises the classification of foodstuffs on the basis of function rather than entirely on chem. compn., with special emphasis on the fact that most of the foodstuffs have deficiencies which are corrected by use of milk and of leafy vegetables. These foods are valuable because of the "fat-sol. A" and "water-sol. B" contained in them.

HELEN N. ELLIOTT.

The use of lime water in the preparation of soldiers' bread. BALLAND. *Compt. rend.* 167, 198-201(1918).—The amts. of lime added to the bread decreased the acidity only slightly. Usually the addition of lime could not be detected by taste and the quality of the bread was little changed.

L. D. ELLIOTT.

A quick method of calculating food values. CAROLINE L. HUNT. *J. Home Econ.* 10, 212-8(1918).—Tables and examples.

L. D. ELLIOTT.

The detection of coconut oil in butter by the Polenske method of distillation and the determination of the melting point of the phytosterol acetate according to Bömer. CHR. BARTHEL AND KLAS SONDEN. *Mon. sci* 8, 268-72(1918).—The  $n_{40}$  is a satisfactory figure for the rapid sorting of butters into genuine and doubtful samples, but because of the comparatively wide limits of the factor for pure butters and the small effect upon it of coconut oil, it cannot be considered more than a preliminary test. The Polenske and R.-M. values of all doubtful butters should be detd., and these factors compared with each other. The Polenske value for a R.-M. No. of 29-30 is about 3.5. The limits for pure butters are 1.7-3.4 and the R.-M. Nos. 25.7-31.2. Five % of coconut oil usually raises the P. No. above 3.4 but if the butter adulterated had a low value itself even 10% of coconut oil could not be detected in this way with certainty. Analyses of butters made from the milk of cows fed with 1.5 kg. of coconut cake per day indicate that such feeding, which is common in France, gives the butter an abnormally high P. No. Palm-nut cake, however, does not affect this figure appreciably. The feeding of beet leaves raises the R.-M. No. of the milk fat and to a lesser extent the P. No. and while the ratio between these two is not quite the same, perhaps, as for normal butter the P. No. may lie between 3.7 and 4.1 which are the figures corresponding to a R.-M. No. of 33.3-34.1, the values found for the butter of cows fed on beet leaf. Other feeds such as the legumes and beet pulp have little effect on the P. No. In those instances where the above tests do not give conclusive evidence of the purity of butter, the m. p. of the phytosterol acetate (Bömer method) should be detd. The m. p. should be between  $113^{\circ}$  and  $116^{\circ}$ , 10% of vegetable oil will raise the m. p. above  $117^{\circ}$  and even 5% can often be detected.

H. S. BAILEY.

Comparative study of the influence of various methods of preparation on the refraction of milk serum. A. J. H. KAM. *Versl. van het Centr. Lab. t. b. v. h. Staat-soets. op de Volksgesondh. over 1917*, 67-9(1918); *Chem. Weekblad* 15, 1390.—Milk serum was prepd. by the following means: spontaneous, HOAc (5 different ways),  $\text{CaCl}_2$ , rennet, asaprol, copper,  $\text{Zn}_2\text{Fe}(\text{CN})_6$ , tartaric acid and trichloroacetic acid. The best serums are the tetraserum of Phyl and Turnau, and those made with  $\text{Zn}_2\text{Fe}(\text{CN})_6$  and with  $\text{CaCl}_2$  according to Ackermann.

JULIAN F. SMITH.

Factors which influence the yield and consistency of ice cream. M. MORTENSEN. Iowa Agr. Expt. Sta., *Bull.* 180, 261-83(1918).—Fresh raw cream produced smaller yields of ice cream than cream which had been allowed to age 24 to 48 hrs., there being a difference of over 6%. The yield from pasteurized cream is also increased by aging.

Aged cream produces an ice cream of a better texture than that produced from fresh cream. Fillers have no influence on the yield of ice cream. A temp. of 6° F. for the brine is most desirable when using a 20% raw cream. For pasteurized cream a temp. of 8° to 10° gave best results. The holding of ice cream does not influence the distribution of fat. The texture, firmness and keeping qualities of ice cream are influenced by the air cells, the fillers added to the mixt. and the milk solids of the cream.

J. J. SKINNER.

**The calculation of the dry matter of milk from the fat and specific gravity.** J. J. OTT DE VRIES. *Vereeniging tot exploitatie eener proefsuivelboerderij te Hoorn; Jahresbericht 1916*, p. 107; *Biedermanns Zentr.* 47, 271-3(1918).—The tentative formula proposed as the result of analyses of twelve samples of Holland milk is  $t = 1.23 \times \text{fat} + 2.56(100s - 100)/s$ , where  $t$  is the dry matter and  $s$  is the specific gravity A. R. MERZ.

**Experiments to improve musty grain. II.** M. HEINRICH. *Versuchsstationen* 90, 49-67(1917).—Supplementing an earlier investigation (*Versuchsstationen* 88, 399 (1916)) on this subject, H. has tested a further method which consists of dusting the grain with a mixt. of powdered freshly ignited CaO and MgO in a bicarbonate compd., permitting this to remain in contact with the grain for a period and then mechanically removing it. The action of this procedure is claimed to be the removal of moisture from the grain by the oxides with the production of heat which causes part of the CO<sub>2</sub> in the bicarbonate to be liberated and change the hydroxides of Ca and Mg into harmless carbonates. The oxides are at the same time destructive of injurious NH<sub>3</sub> compds. which are formed in the moist store-room. The following results were established: No noticeable diminution of the moisture content was obtained in any case. With oats of moderately high moisture content the powder had a slight favorable action on the germinative power though it is questionable whether this is of practical significance. With oats of high moisture content there was no effect if storage was with free access of air. If storage was air-tight injury resulted from promotion of bacteria activity.

ALBERT R. MERZ.

**Occurrence and origin of nitrites in sausage and meats.** H. W. VAN URK. *Pharm. Weekblad* 55, 1450-5(1918).—In the usual practice, any nitrite present in meat preps. is detd. as nitrate. It would be much better to det. nitrites separately, since expts. have shown that a high nitrite content may be an indication of decay in meats. The origin is ascribed to reduction by microorganisms of added saltpeter. J. F. SMITH.

**Studies on the food plants of Formosa. I.** O. OKUMURA. *J. Tokyo Chem. Soc.* 39, 983-97(1918).—The swellings on *Fizania latifolia* Turcz., caused by the attack of *Ustilago esculenta*, P. Henn., are used as a food in the orient. A sample obtained from the Agr. Expt. Station ground, Formosa, Japan, gave the following analysis: H<sub>2</sub>O 90.36%, ash 0.58%, crude protein 1.03, protein N 0.16, non-protein N 0.05, Et<sub>2</sub>O ext. 0.69, crude fiber 0.87, sol. non-N matter 6.19, reducing sugar 3.46, dextrin 0.21, starch 1.22, pentosan 0.82; the ash contains SiO<sub>2</sub> 4.17, SO<sub>2</sub> 4.58, Cl 1.36, P<sub>2</sub>O<sub>5</sub> 3.71, Fe<sub>2</sub>O<sub>3</sub> 2.78, Al<sub>2</sub>O<sub>3</sub> 6.93, Mn<sub>2</sub>O<sub>3</sub> 0.27, CaO 0.39, MgO 1.78, K<sub>2</sub>O 55.28, Na<sub>2</sub>O 1.67%. From the warm 50% alc. ext., *d*-glucose was isolated; this is the main constituent of the reducing sugars. Adenine, histidine, arginine, stachydrin and choline were found in the 80% alc. ext.

S. KOMATSU.

**Chemistry of sweet-clover silage in comparison with alfalfa silage.** C. O. SWANSON AND E. L. TAGUE. *Kans. Agr. Expt. Sta. J. Agr. Research* 15, 113-32(1918); cf. C. A. 11, 2834.—In milk bottle containers silage was made from alfalfa, sweet-clover, and sweet-clover + ground corn 10:1. At intervals 3 samples were removed. Upon 1 detns. were made of loss of wt. and total H<sub>2</sub>O content. The 2nd sample was dild. with 4 times its wt. of H<sub>2</sub>O and to the 3rd enough EtOH was added to make the EtOH content

50%, and the H<sub>2</sub>O and EtOH extracts were used for detns. of: acidity as shown by titration with phenolphthalein and also by using the H electrode; amino N as shown by the method of Sorensen (*Biochem. Z.* 7, 45-101) and also by a modification of Sorensen's method using the H electrode to det. the end-point; total N; and total N not pptd. with phosphotungstic acid. The loss in wt. was approx. 1% on all samples. When titrated against phenolphthalein the alc. ext. showed higher acidity than the H<sub>2</sub>O ext., but using the H electrode and titrating to  $P_H$  8.3 the two exts. gave concordant results. The acidity of the 3 silages increased sharply for the 1st 15 days and then more gradually until about the 50th day; after this there was very little increase. The alfalfa required about twice as much alkali as the sweet-clover and the clover + corn had an acidity about midway between the two. The alfalfa silage was also higher in amino N than was the silage from the sweet-clover, while the addition of corn to the clover had little effect. The total N was about twice the amino N in all cases. The results would indicate that silage can be made from sweet-clover more easily than from alfalfa.

Somatose (THOMSON) 11B. Tomato seeds (ANON.) 27. Effect of heat on the spores of *Bacillus botulinus* (BURKE) 11C. Determination of sugar in milk (SJOLLEMA) 11B.

---

**Desiccated milk.** C. H. CAMPBELL. U. S. reissue 14,567, Dec. 17. See original pat. 1,233,446; C. A. 11, 2595.

**Cocoa fat; theobromine; caffeine.** E. DE GROUSSEAU and A. VICONGNE. Brit. 120,178, June 4, 1918. To obtain fat, theobromine, and caffeine from cocoa and chocolate waste, the waste is treated with a mixt. of tetrachloroethane and phenol in the presence of aq. NH<sub>3</sub>. The solvents are removed from the ext. thus obtained by distn., and the fat is removed from the residue by a solvent such as petroleum ether or dichloroethylene. The theobromine and tannin are next removed by treatment with soda or potash, and the theobromine is pptd. free from tannin by CO<sub>2</sub>. The extg. and distg. app. are specified. Cf. C. A. 12, 2111.

**Coffee substitutes.** J. L. KELLOGG and B. KAZMANN. Brit. 120,121, Nov. 15 1917. A dry sol. ext. for use as a substitute for coffee is formed by extg. with H<sub>2</sub>O a partially dextrinized and roasted starch-bearing material, and evapg. the ext. As starch-bearing materials, legumes, tubers, roots, fruits such as bananas, seeds such as cottonseed, St. John's bread, or algaroba beans, grain such as wheat, rye, barley, corn, Kaffir corn or rice, or fat-bearing beans such as soy beans or peanuts, may be used. Preferably a mixt. of wheat flour, rye flour, and bran or whole meal is used. The material is mixed with H<sub>2</sub>O, the dough obtained is formed into loaves which are heated under steam pressure for some time, to form dextrin. The loaves are allowed to dry in the air, pulverized, the particles are further dried, roasted, extd. with H<sub>2</sub>O, and the liquid ext. is evapd. and dried *in vacuo*. Cf. 17,255, 1915 (C. A. 11, 1501).

**Coffee substitutes.** J. L. KELLOGG and B. KAZMANN. Brit. 120,279, Nov. 15, 1917. In prepg. a coffee substitute by partially dextrinizing and roasting starch-bearing materials, as described in 120,121 (*supra*), malt, malt ext., *Aspergillus oryzae*, or other diastatic ferment or enzyme is added to the materials and the formation of maltose is prevented by the heating to cause dextrinization. The steps of extg. the roasted material and evapg. the ext. may be omitted.

**Leavening mixture.** F. B. LA FORGE. U. S. 1,288,428, Dec. 17. A mixt. of gulonic lactone with NaHCO<sub>3</sub> is prepd. for use as a leavening agent. The pat. is dedicated to the public for free use without payment of royalty.

## 14. WATER, SEWAGE AND SANITATION.

EDWARD BARTOW AND W. F. MONFORT.

Can water for analysis be kept several days in the refrigerator? P. A. A. F. RIJKEN. *Geneesk. Tijdschr. voor Ned. Indië* 58, 163-7; *Chem. Weekblad* 15, 1519(1918).—This investigation showed that it is not advisable to keep water for bacteriol. analysis overnight in the refrigerator, even at 0°.

JULIAN F. SMITH.

Report on the investigation of the water supply for Banjermasin. G. GRIJNS. *Geneesk. Tijdschr. voor Ned. Indië* 58, 28-42; *Chem. Weekblad* 15, 1520(1918).—Bacteriol. analysis was used to decide which of 3 possible sources was the best to provide drinking water for Banjermasin.

## 15. SOILS, FERTILIZERS AND AGRICULTURAL POISONS.

J. J. SKINNER.

The classification of soils according to their electric conductivity. BÉLA VON HORVÁTH. *Intern. Mitt. Bodenk.* 6, 231(1916); *Biedermanns Zentr.* 47, 283(1918).—After describing the method used for the detn. of the cond. of soils the values found are arranged and compared with the soil types. The conclusion is reached that an exact classification of all soils by this means is impossible. The circumstance that in the artificial alteration of the sequence of the soil strata, such as is brought about by plowing, the cond. of the uppermost layer is altered renders the possibility of such a classification especially questionable. The data given show plainly, however, that the cond. of a soil varies with depth.

ALBERT R. MERZ.

The alkali soils of Iowa. R. L. BANCROFT. *Iowa Agr. Exp. Sta., Bull.* 177, 187-232(1918).—In the alkali soils of this state Ca(HCO<sub>3</sub>)<sub>2</sub> is the principal salt. Other more harmful salts occur in insufficient amts. to be dangerous. These soils are reclaimed by drainage and applying farm manure. The greatest % of sol. salts is present in low areas in pasture soils, while in cultivated soils the amt. is much

greater at the high elevation, this being due to lack of drainage in the pasture soils, the salts accumulating in the low places. In the cultivated soils the salts are removed first from the lower places and more gradually from the higher places.

J. J. SKINNER.

The phosphoric acid in calcined soils. JOSEF SEISSL. *Z. landw. Versuchs.* 20, 212(1917); *Biedermanns Zentr.* 47, 241-3(1918).—Twenty-four soils were ignited in order to destroy the org. matter contained. The content of  $P_2O_5$  sol. in  $HNO_3$  (d. 1.2) after ignition exceeded that before ignition by 20 to 40%. The organically bound  $P_2O_5$  occurs in the form of proteins or as lecithins or phosphatides which are derived from the subterranean portions of plants or from incorporated leaves, the straw of stable-manure, the indigestible and undigested portions of animal food and the dead bodies of insects, snails, worms, etc. The relative order of availability for plant nutrition of org.  $P_2O_5$  compds. is lecithin, phytin and nuclein. Besides the direct absorption of these by plants there is undoubtedly a gradual decompn. into simpler org. and even inorg. compds. (processes promoted by the presence of basic substances such as lime and liquid manure) through the activity of microorganisms. ALBERT R. MERZ.

Studies on proteolytic activities of soil microorganisms, with special reference to fungi. SELMAN A. WAKSMAN. *J. Bact.* 3, 475-92(1918).—Different organisms behave differently in their power to attack proteins and in the production of amino N and  $NH_3$ . Most of the molds which grow very rapidly, as manifested by the increase in wt. of their mycelium, allow a small amt. of amino N to accumulate in the medium, while the amt. of  $NH_3$  accumulated increases with the period of incubation. Certain molds, particularly the slower growing ones, the actinomyces studied, and *B. mycoides* favor a large accumulation of amino N in the medium and a comparatively smaller accumulation of  $NH_3$ . The growth of *Aspergillus niger* upon a soln. containing peptone shows that the amino N produced in the medium is used by the organism, so that no great accumulation takes place.  $NH_3$ , on the other hand, which seems to be a waste product of the metabolism of the organism, accumulates readily in the medium, particularly when the organism stops growing and begins to autolyze. The process of ammonification in the presence of available carbohydrates, is found to be an autocatalytic chem. reaction. In the absence of available carbohydrates, the observed data deviated from the data calcd. by the use of the curve of autocatalysis. The study of ammonification is of doubtful importance in revealing the proteolytic activities of microorganisms, since the quantity of  $NH_3$  accumulated in the medium depends on a great number of controlling factors; it has not been proved as yet that  $NH_3$  is an end product of protein metabolism. Asparagine N is rapidly converted into  $NH_3$ , after the organism has made its max. growth; but, where the atm. of asparagine N is small, particularly in the presence of a comparatively large excess of available carbohydrates, no  $NH_3$ , or only a very small quantity of it, will accumulate in the medium.

JOHN T. MYERS.

The way in which nitrates and nitrites are formed in bog soils. TH. ARNDT. *Landw. Jahresb.* 51, 297-328(1917); *Biedermanns Zentr.* 48, 291-4(1918).—The theory, recently advanced by G. A. Ritter (*C. A.* 8, 1180) and based on his expts. with peat soil, that there is a possibility of the formation of nitrates chemically without the intermediation of nitrifying organisms in addition to their formation by the action of nitrifying bacteria could not be verified by A.'s expts. None of the samples of un-inoculated soil, regardless of whether or not  $CaO$ , nutritive ammoniacal soln. or  $(NH_4)_2SO_4$  or  $HgCl_2$  were added, showed any formation of  $HNO_3$  or  $HNO_2$  during the time of the expt. The quantities of  $NH_3$  originally present or added were still present at the expiration of the expt. in the limed and unlimed samples to which  $HgCl_2$  had been added; there was an evident diminution of  $NH_3$  due to assimilation of the ammoniacal

N in the limed samples to which  $\text{HgCl}_2$  was not added. Similarly no  $\text{HNO}_2$  formation took place in the unlimed samples inoculated with sandy soil or "Rohkultur;" the limed soils which had not received any  $\text{HgCl}_2$  showed, however, an active formation of  $\text{HNO}_2$ . "All exts. of samples which had been kept sterile with  $\text{HgCl}_2$ , whether limed or unlimed, inoculated or un-inoculated, or to which  $\text{NH}_3$  had or had not been added, showed that nitrification had taken place." The traces of  $\text{HNO}_2$  which were found in the inoculated samples were derived from the nitrate-containing sandy soil or the raw culture of nitrifying bacteria which naturally also contained nitrates. To meet the objection that the time chosen for the expts. was not sufficient a series of upland bog soils obtained from the collection of the institution was subjected to qualitative tests for  $\text{NH}_3$ ,  $\text{HNO}_2$  and  $\text{HNO}_3$ . These samples were gradually dried in the air at ordinary temp. With exception of one, which contained traces of  $\text{HNO}_2$ , all these soils contained  $\text{NH}_3$  and were entirely free from nitrites and nitrates. If the assumption of Ritter that there was a nitrification in raw, drying upland bogs were correct these would naturally have to give distinct reactions for nitrate. A. R. MERZ.

**The influence of plant residues on nitrogen fixation and on losses of nitrates in the soil.** H. B. HUTCHINSON. *J. Agr. Sci.* 19, Pt. 1, 92-111(1918).—Lab. expts., plot, and field tests were performed with soils and sand, using dextroses, sucrose, straw, and wheat stubble ground with elm leaves. The data corroborate the work of others and give definite evidence that the N content of sand or soil may be increased by the activity of *Azotobacter* when a suitable source of energy is supplied, sugars being the most effective, but plant residues are also beneficial. The lab. and field expts. agreed closely. The general soil conditions making for the successful operation of N-fixation are, in addition to the supply of some source of energy, a suitable temp., presence of phosphates, and basic materials such as  $\text{CaCO}_3$ . In order to avoid adverse processes, which finally adjust themselves, a crop should not be planted immediately following the application of the materials. Temp. is an important factor in detg. the duration of these adverse changes. R. B. DERMER.

**The influence of potsherds on nitrification in the Indian alluvium.** J. N. SEN. *J. Agr. Sci.* 9, Pt. 1, 32-42(1918).—From the detn. of nitrates in the percolates, which were obtained from mixts. of 3 lbs. per cu. ft. of barnyard manure and fine alluvial soils of Pusa with varying amts. of potsherds (0, 10, 20, and 30%) in jars, it appears that potsherds increase nitrification and that 30% are most beneficial. This is attributed to the introduction of more O into the soils which oxidizes the org. matter. In order to study the effect of drainage upon nitrification lysimeter pits, having only soil walls, were constructed and filled with manured soil of the same compn. and percentages of potsherds used in the pot expt. Soil samples were taken for the detn. of nitrates. In general the pits containing 30% potsherds contained the largest amts. of nitrates. The expts. extended over a period of 8 months or more. In the lysimeter expt. it was observed that in each tank the amt. of nitrates was practically the same for the first 3 months, a fact found to be true in actual practice. The influence of the rise and fall of a nearby river upon the amt. of nitrates in the soil is also discussed in detail. R. B. DERMER.

**Stable manure and nitrification in the soil.** II. CHR. BERTHEL AND N. BENGTSSON. *Kungliga Landbruks-Akad. Handlingar Tidskrift.* 57, 353-367(1918).—This part of the series of expts. on the nitrification of stable manure N in soil is concerned with the influence of Ca. The Ca is added as  $\text{CaCO}_3$ .  $\text{CaCO}_3$  in ordinary amts. seems to have no influence whatever. If the  $\text{CaCO}_3$  is added in large amts. it has an inhibitory effect but this is merely of academic interest, as the amts. needed to produce this are much above the amts. that will be used in ordinary agricultural practice. A. R. ROSE.

**Rational preparation of superphosphates.** Study of the relations connecting the technical process of preparation of superphosphates, chemical constitution and physico-mechanical characters of the product. A. AITA. *Ann. chim. applicata* 10, 45-103 (1918).—As regards the chem. process the industrial prepn. of superphosphates is to-day still carried out in an empirical direction. Only lately has important work been done in this field (Pratolongo, cf. *C. A.* 10, 3130; Aita, cf. *C. A.* 11, 682). Pratolongo asserts that the content in free  $\text{H}_2\text{PO}_4$  of superphosphates, besides depending upon the stoichiometrical relations of the reagents, is a close function of the temp. of reaction of formation. A. points out that this statement is clearly in contradiction to the detd. fact in the technical process of superphosphate prepn., i. e., that the use of concns. of  $\text{H}_2\text{SO}_4$  greater than ordinarily employed, effects a remarkable improvement in the physico-mechanical state of the product. To clear up this contradiction A. investigated the subject anew in order to verify and control the methods of extn. of free  $\text{H}_2\text{PO}_4$  from superphosphates. He then extended his studies further. In the system  $\text{H}_2\text{PO}_4\text{--CaO--H}_2\text{O}$ , which exists essentially in the system  $\text{H}_2\text{PO}_4\text{--CaO--H}_2\text{O--H}_2\text{SO}_4$  representing the formation of superphosphate, the following is true: Normally in it there is a solid phase formed of  $\text{CaH}_4(\text{PO}_4)_2$  and  $\text{CaHPO}_4$ , and a liquid phase composed not only of  $\text{H}_2\text{PO}_4$  and  $\text{H}_2\text{O}$  but also of  $\text{CaH}_4(\text{PO}_4)_2$ ; the estn. of the free  $\text{H}_2\text{PO}_4$  and of the  $\text{CaHPO}_4$  depends upon the quantity of  $\text{H}_2\text{O}$  that makes a part of the solid phase. Since com. superphosphates run from 12 to 20% in sol.  $\text{P}_2\text{O}_5$  and from 10 to 20%  $\text{H}_2\text{O}$ , they represent high concns. of  $\text{P}_2\text{O}_5$  in contact with low quantities of  $\text{H}_2\text{O}$ . On the basis of the statement above, the ideal superphosphate would have a content of free  $\text{P}_2\text{O}_5$  of from  $1/20$  to  $1/10$  of the total sol.  $\text{P}_2\text{O}_5$ . With this in view A. compared the estn. of free  $\text{P}_2\text{O}_5$  by the various methods available—extn. by 95% alc., abs. alc., acetone, anhydrous  $\text{Et}_2\text{O}$ ,  $\text{H}_2\text{O}$  either with direct titration or after addn. of K oxalate. If the solvent neither dissolves nor hydrolyzes the  $\text{CaH}_4(\text{PO}_4)_2$ , it will ext. from the product not the entire liquid phase but only  $\text{H}_2\text{O}$  and free  $\text{H}_2\text{PO}_4$ . With solvents absolutely anhydrous (e. g.,  $\text{Et}_2\text{O}$  free of  $\text{H}_2\text{O}$  by distn. over Na) there is not the least trace of CaO in the ext. Aq. solvents on the other hand, give exts. containing more or less considerable portions of CaO, which varies according to the proportion of  $\text{H}_2\text{O}$  present. Therefore extn. with  $\text{Et}_2\text{O}$  is the only method which furnishes results approximating to the content in free  $\text{H}_2\text{PO}_4$  theoretically, corresponding to the system  $\text{H}_2\text{PO}_4\text{--CaO--H}_2\text{O}$ . The aq. solvents, owing to their hydrolyzing action upon  $\text{CaH}_4(\text{PO}_4)_2$ , ext. from superphosphate appreciably greater fractions of  $\text{P}_2\text{O}_5$ , varying according to the amt. of  $\text{H}_2\text{O}$  they contain. Abs. alc., while containing no  $\text{H}_2\text{O}$ , behaves like an aq. solvent, the presence of the OH group in its structure causing hydrolysis of the  $\text{CaH}_4(\text{PO}_4)_2$ . Acetone may serve for extn. of free  $\text{H}_2\text{PO}_4$  from superphosphate if perfectly pure and anhydrous. By the use of the  $\text{Et}_2\text{O}$  extn. method, A. arrived at these conclusions from various expts. on preps. of superphosphate: (1) Fresh preps. have a higher content of  $\text{P}_2\text{O}_5$  than those seasoned; (2) free  $\text{H}_2\text{PO}_4$  of the liquid phase becomes gradually less and less and tends towards the theoretical amt. in normal superphosphates prepd. by exact stoichiometrical conditions of the reagents; in other words, the conditions altered by the temp. of the reaction during the technical process of prepn. proceed slowly to renew the definite equil. outlined in the system  $\text{H}_2\text{PO}_4\text{--CaO--H}_2\text{O}$ . These considerations (outside of the error due to his method of extn.) explain the increase in content of free  $\text{H}_2\text{PO}_4$  found by Pratolongo in samples of superphosphate treated in a closed tube in an autoclave at elevated temp. These increases correspond to states of false equil. so that the stable equil. altered by the temp. is not restored to the product except after a relatively long lapse of time. The  $\text{H}_2\text{O}$  contained in superphosphate (using the knowledge of the system  $\text{H}_2\text{PO}_4\text{--CaO--H}_2\text{O}$  as guide) can be looked upon as making up 2 fractions:— $\text{H}_2\text{O}$  of crystn. of the solid constituents,  $\text{CaH}_4(\text{PO}_4)_2$ ,  $\text{CaHPO}_4$ ,  $\text{CaSO}_4$ , and humidity, or more properly, the portion of  $\text{H}_2\text{O}$

moistening the product and forming part of the liquid phase. The distinction between these 2 fractions cannot be effected by the ordinary methods of drying at different temps. because heating of superphosphates liberates other substances than  $\text{H}_2\text{O}$ . *e. g.*,  $\text{HF}$ ,  $\text{SiF}$ , besides  $\text{H}_2\text{O}$  of crystn. of some of the salts of the product. Also increase of temp. creates various labile states of equil. in the chem. system out of which the superphosphate is formed, so that there does not correspond to a given temp. any definite state of the system and of the product. Therefore Pratolongo's method of detg. "true humidity" and  $\text{H}_2\text{O}$  of crystn. is erroneous and misleading. The use of  $\text{Et}_2\text{O}$  instead of  $\text{EtOH}$  avoids the errors of Pratolongo's method. A.'s method is as follows: Ext. 2 g. of the superphosphate with  $\text{Et}_2\text{O}$ , dry the fiber (previously tared) together with the residue in an oven at  $40^\circ$ , and weigh. The difference this wt. and the orig. 2 g., less the amount of free  $\text{H}_3\text{PO}_4$  found in the  $\text{Et}_2\text{O}$  ext., is the measure of the  $\text{H}_2\text{O}$  of the liquid phase. Keep then in a desiccator over 95%  $\text{H}_2\text{SO}_4$  to const. wt. The difference between the final wt. and the previous wt. gives the amount of  $\text{H}_2\text{O}$  of crystn. of the solid constituents. A. gives tables of superphosphates derived from various phosphorites, showing total  $\text{P}_2\text{O}_5$ ,  $\text{P}_2\text{O}_5$  sol. in  $\text{H}_2\text{O}$  and citrate,  $\text{P}_2\text{O}_5$  in the form of  $\text{H}_3\text{PO}_4$  extd., resp., with  $\text{Et}_2\text{O}$ , com.  $\text{Et}_2\text{O}$ , abs. alc., and 95% alc.;  $\text{H}_2\text{O}$  of the liquid phase and that of crystn., the acid used, the seasoning of the superphosphate, and its physico-mechanical properties. A. concludes (1) that the physico-mechanical characters of the superphosphate depend on the content of the product in  $\text{H}_2\text{O}$  and free  $\text{H}_3\text{PO}_4$  taken together. The free  $\text{P}_2\text{O}_5$  varies from 0.15 to 9.07%, the  $\text{H}_2\text{O}$  of the liquid phase from 1.33 to 15.90% and the  $\text{H}_2\text{O}$  of crystn. from 1.10 to 4.90%. (2) Free  $\text{H}_3\text{PO}_4$  and  $\text{H}_2\text{O}$  of superphosphate are intimately bound together, this condition depending particularly upon the concn. of the  $\text{H}_2\text{SO}_4$  employed, on the stoichiometrical conditions of the reagents taking part in the process of formation, but not depending upon the temp. of the reaction. A. divides superphosphates of commerce into 2 classes—normal and abnormal, the first class including those prepd. under exact conditions of stoichiometrical relations between reagents and with not too low concd. acid., the 2nd class including products obtained by defective treatment, either because of excess of  $\text{H}_2\text{SO}_4$ , of low concn. of  $\text{H}_2\text{SO}_4$  or both. J. Kolb (*Compt. rend.* 78, 825) inferred that the technical reaction of formation of superphosphates was carried out in 2 phases, (a) reaction of  $3\text{Ca}_3(\text{PO}_4)_2$  with  $6\text{H}_2\text{SO}_4$  to form  $4\text{H}_3\text{PO}_4$ ,  $\text{Ca}_3(\text{PO}_4)_2$  and  $6\text{CaSO}_4$ ; (b) reaction between  $\text{Ca}_3(\text{PO}_4)_2$  and  $4\text{H}_3\text{PO}_4$  to form  $3\text{CaH}_4(\text{PO}_4)_2$ . A., from analysis of the mixt. of phosphorite and  $\text{H}_2\text{SO}_4$  at different stages of the reaction, concluded that the  $\text{Ca}_3(\text{PO}_4)_2$  is attacked exclusively by the  $\text{H}_2\text{SO}_4$  in one reaction with formation of  $\text{CaH}_4(\text{PO}_4)_2$  and  $\text{CaSO}_4$ , with a velocity of reaction depending upon the fineness, nature and content in  $\text{CaO}$  of the phosphorite. In detg. the amount of  $\text{H}_2\text{SO}_4$  to be used to give the largest amount of sol.  $\text{P}_2\text{O}_5$  in the superphosphate, the method generally employed is to make repeated tests on new lots of phosphorite on the industrial scale, using varying amounts of  $\text{H}_2\text{SO}_4$ , and checking by analysis of the product. A. believes that equally good or better results can be obtained by the use of empirical factors in connection with the principal components of the phosphorite employed, *e. g.*,  $\text{Ca}_3(\text{PO}_4)_2$ ,  $\text{CaCO}_3$ ,  $\text{Fe}_2\text{O}_3$  and  $\text{Al}_2\text{O}_3$ . The losses sustained by the mixt. of phosphorite and  $\text{H}_2\text{SO}_4$  depend largely on the temp. of the reaction. The temp. in turn depends upon the following factors: temp. of the reagents, concn. of the  $\text{H}_2\text{SO}_4$ , fineness of the phosphorite meal, nature of the phosphate mineral, and quantity of charge of the reagents. It is most desirable to employ in industrial prepn. the greatest concn. of  $\text{H}_2\text{SO}_4$  for the mixt. which is permitted by the app. in use and by reasons of a technical nature. A. considers 3 types of grinding mills: (a) Krupp ball mill, (b) Griffin hammer mill, (c) Kent roller mill. Types (b) and (c) are more recent and are preferred in modern plants to the ball mill because they are easier to handle and give comparatively higher yields for the same power consumption. A. studied the grinding action of (b) on different
